Dr. A. J. McCosh of New York City has written on the surgical treatment of septic peritonitis. In describing the use of saline solution for irrigation of the peritoneal cavity we think it would have been as well to have mentioned how this solution should be made; it is not sufficient to say, "Salt solution in physiological strength." Tuberculous peritonitis has been discussed by Dr. Nathan Jacobson of Syracuse, New York. The author considers that the best results from operations for this affection are obtained when manifestations have become stationary. Dr. E. Wyllys Andrews of Chicago, Illinois, has contributed the article on hernia. He describes fully his original method of radical cure of inguinal hernia, and his method appears to have been the first in which overlapping of the cut edges of the fasciæ was considered of importance. Dr. McCosh has also written the chapter on diseases of the appendix, which represents the current views on this important subject, and it is especially good in that part which deals with the analysis of the symptoms which may be present with appendicitis. Dr. C. W. Oviatt of Oshkosh, Wisconsin, has contributed the section on the surgery of the intestines, omentum, and mesentery. It is well illustrated. The account of colostomy is hardly sufficiently detailed.

Dr. J. P. Tuttle of New York City, and Dr. S. T. Earle of Baltimore, have described the surgery of the anus and rectum, and they have acted wisely in commencing their articles with an account of the anatomy of this region. This article occupies nearly 200 pages, and is as satisfactory as the names of its authors would suggest. The authors speak very highly of the perineal operation for removal of malignant disease of the rectum, and they advise that whenever a rectal tumour cannot be removed by the perineal method it should be treated either by the abdominal method or the combined method. In this section we have a very satisfactory account of appendicostomy.

Technical Mycology: The Utilisation of Micro-organisms in the Arts and Manufactures. By Dr. FRANZ LAFAR. Translated by CHARLES T. C. SALTER. Vol. II., Eumycetic Fermentation. Part II., with 50 figures in the text. London: Charles Griffin and Co., Limited. 1910. Pp. 748. Price 18*s.* net.

THIS publication completes a series of three volumes upon a very interesting and important subject. The publication of the concluding number with index has been considerably delayed owing to a difficulty in obtaining the final sheets from the German publishers. Seven years have, in fact, elapsed since the previous volume was issued, a review of which appeared in our columns of July 11th, 1903, p. 104. This delay has perhaps not been without its advantages, as, for one thing, it has given the author an opportunity of bringing his materials into line with modern contributions. The importance of the subject grows rapidly day by day, for great departments of industry depend for their success upon an accurate knowledge of the life-history and habits of micro-organisms. The author possesses an intimate knowledge of the subject gained largely from the fact of his occupying the position of professor of fermentation-physiology and bacteriology in the Imperial Technical High School at Vienna, and he may be congratulated upon the completion of a work which, so far as we know, is the only compilation of its kind. In this he has had the advantage of the assistance given by some distinguished German authorities on the significance of fermentations. The volume before us contains five important sections of the subject of eumycetic fermentation, which are dealt with in the following order: Section XIII., Yeast Nutrition and Yeast Culture; Section XIV., Life-history and Variability of the Saccharomycetes, with a Classification of Saccharomycetes and Schizosaccharomycetes; Section XV., Morphology and Classification of Certain Technically Important Higher Ascomycetes and Allied Forms; Section XVI., General Morphology, Physiology, and Classification of Technically Important Budding Fungi of the Group "Fungi Imperfecti"; and Section XVII., the Enzymes and Enzymic Actions of Yeast. A consideration of these headings will indicate what an important number of technical applications are involved. To mention a few, the great brewing industry would soon bring disaster upon itself if care was not taken to select a healthy race of yeast; the manufacture of cheese is rapidly becoming a standardised and healthy process by paying attention to the habits of the organisms concerned in its production; the quality of tobacco, again, is largely a matter of organism activity; thousands of butts of wine have been spoilt by disregarding the exact conditions under which the organised activities convert the juice into wine; and oftentimes the grape harvest might have been saved from ruin if only preventive measures based on a knowledge of the nature of the attacks of disease had been applied. In short, there is a pathology of art and industry which, when it comes to be studied in all its details, promises to lead to a handsome reward in the shape of an assured yield of produce of a uniform wholesome character. The labours which help this movement forward need no commendation from us; we regard Professor Lafar's work as invaluable alike to the student and to the practical man.

Allen's Commercial Organic Analysis. Vol. III. Edited by W. A. DAVIS, B.Sc., A.C.G.I., and SAMUEL S. SADTLER, S.B. London: J. and A. Churchill. 1910. Pp. 635. Price 21*s.* net.

WITH each succeeding volume the reader of the original "Allen's Commercial Organic Analysis" will recognise the gradual insertion of the work of new hands and the disappearance of the school of the old master and his pupils. For our part we are sorry that some effort was not taken to

preserve the style and method of treatment outlined by the original author. As it is, the work is rapidly approaching a shape in which all traces of the original design are lost, and somehow there was an attractive personality about Allen's work which is missing in the new edition. He wrote his work, we may say, in the laboratory, for every paragraph appeared to be the result of practical personal experience gained at the bench, and when the laboratory student wanted information on experimental points he invariably found it—he was led straight to a trustworthy test, and was warned of fallacies which might arise in connexion with it. Mr. Allen, of course, took a strong practical interest in analyses relating to foods and medicines, and his experience on these points was valued; and we think we are right in saying that it was on account of this experience that his work enjoyed a considerable reputation. "Commercial Organic Analysis" is, however, a wide title, and we are not surprised that the technological or industrial side of the subject has demanded development. The present volume, for example, is almost exclusively technological or industrial, if we leave out the section on aromatic acids, in which certain drugs (e.g., oil of bitter almonds, tolu, and storax) have clearly to be discussed, and the salicylates in their rôle as preservatives of food. The rest of the chapters deals with hydrocarbons, bitumens, naphthalene and its derivatives, anthracene and its associates, phenols, aromatic acids, gallic acid, phthalic acid, and modern explosives. There is no relief from technology here, and the editors acknowledge their indebtedness to four technological chemists in America connected with coal and iron works, tar distilleries, and asphalt production. Dr. Leffmann has ceased to continue as American editor owing to pressure of work elsewhere, and he is succeeded by Mr. Samuel S. Sadtler of Philadelphia, who is responsible for the articles on bitumens, anthracene, and phenols. The subsection of the chapter on phenols dealing with phenolic disinfecting liquids is disappointing in analytical particulars, having regard to the considerable attention which this subject has received within recent years. On the other hand, in the section on aromatic acids there is recent and useful information relating to the detection and estimation of antiseptics in food.

There are yet five volumes to come, and a glance down the synopses of these shows that we may confidently expect a very interesting series of monographs written by a well-recognised authority in each case.

LIBRARY TABLE.

Bier's Hyperemic Treatment, in Surgery, Medicine, and the Specialties: a Manual of its Practical Application. By WILLY MEYER, Professor of Surgery at the New York Post-Graduate Medical School and Hospital, and Professor Dr. VICTOR SCHMEIDEN, Assistant to Professor Bier, University of Berlin. Second revised edition, enlarged. Illustrated. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 280. Price 13*s.* net.—The value of the treatment introduced by Bier has received throughout the world due recognition, but there are still many who are not conversant with the methods of application of the treatment and who would be willing to employ it if they knew how to apply it. As was natural with a new method of treatment, somewhat extravagant claims were made at first by some of the exponents of the Bier treatment, and an entirely undeserved opprobrium which in some cases followed was due to the unintelligent application of the method. It is, therefore, in the mode of application of Bier's treatment that the great need for instruction exists, and we are glad to see that the exposition by Professor Willy Meyer and Dr. Victor Schmeiden has reached a second edition. It contains the information required in a more easily assimilable condition than do the original writings of Bier, and, moreover, it contains later applications of the method than are to be found in any other work. The book is well worthy of careful study by those who are only imperfectly acquainted with the subject, while a valuable bibliography concludes the volume.

Manuel de Neurologie Oculaire. Par F. DE LAPERSONNE, Professeur de Clinique Ophtalmologique, et A. CANTONNET, Chef de Clinique Ophtalmologique à la Faculté de Médecine de Paris. With 106 figures. Paris: Masson et Cie, 1910. Pp. 368. Price 6 francs.—The ever-growing specialty of ophthalmology is divisible into three branches—optic, surgical, and medical. The compactly and lucidly written volume before us is concerned solely with the third of these divisions, and commends itself alike to the oculist and the neurologist. Nor ought the limits of its serviceableness to be thus confined, for owing to an excellent index—a feature that does not characterise all the volumes produced by our continental *confrères*—it may be regarded as a dictionary of clinical ophthalmology wherein the general practitioner will find references to any symptom of an ocular or visual nature that he is likely to be confronted by. The first part of the book is analytical, and consists of an anatomical description of the different systems of the eye, motor, sensory, visual, vaso-motor, and secretory, each of which is followed by a corresponding description of the physiology, and finally of the physiological pathology, of the system. Thus there is no structure, peripheral or central, no function, simple or complex, no symptom of low or high level, that is not adequately considered. A medical review *d'ensemble* of this kind is not readily accessible in ordinary text-books, and the authors deserve hearty congratulations on the way in which their task has been performed. The second part of the book is synthetic: ocular and visual affections in diseases of the nervous system, the digestive, respiratory, circulatory, and genito-urinary systems are fully and concisely set forth, as also in various intoxications and infectious diseases. We can cordially recommend the volume to all who are interested in the scientific side of the subject, as well as to any who merely desire a work of reference for ocular or visual symptoms.

A Prescriber's Companion. By THOMAS D. SAVILL, M.D. Lond. Fourth edition. Revised by the Author, assisted by CHARLES F. HARFORD, M.A., M.D. Cantab., Principal of Livingstone College. London: Henry J. Glaisher. 1910. Pp. 59. Price 1*s.* net.—This little book contains a large number of convenient prescriptions, a list of the doses of the more important drugs, directions for preparing fomentations and baths, and many other things likely to be of use to the busy practitioner. The section on serum and vaccine therapy, though brief, is likely to prove useful; it was entirely rewritten by Dr. Savill within a few weeks of his death. Not the least valuable section is that dealing with the antidotes of the more common poisons.

The Science of Happiness. By HENRY SMITH WILLIAMS, M.D., LL.D. London and New York: Harper and Bros. 1910. Pp. 350. Price 7*s.* 6*d.* net.—We welcome the increasing popularity of the doctrine that the moral life, with its self-knowledge, self reverence, and self-control, is a sure high road to happiness. It is of good augury when the youth of a nation are taught that virtue is not a continual painful struggle after the unattainable, but rather the obedience to hygienic laws of life, which brings its own reward in lifelong happiness. The volume under review should have a wide circulation, because Dr. Smith Williams preaches healthy-minded obvious common-sense. His illustrations from physiological laws of health are just and practical, his examples from history are apt and to the point, he has not weighted his matter with descriptive methods culled from Yogi

practices or mystic auto-suggestive repetitions of absurd phrases. He discusses his subject under four headings—(1) the physical aspect of happiness, which involves obedience to laws of health; (2) mental (education of the memory and reason); (3) social; and (4) moral. He resembles his compatriots in that he advises the frank pursuit of material success. Time alone will show whether this modern philosophy will stand the test of the suffering and the pain and the self-sacrifice which the wisdom of the ages tells us are real and which have proved in the past to be the cleansing fires necessary for the highest growth of the human character.

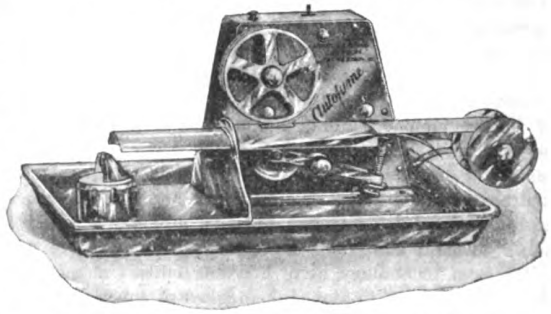
Science German Course. By E. W. PAGET MOFFATT, M.A. Lond., M.B., B.C. Camb. Second edition, enlarged. The University Tutorial Series. London: W. B. Clive. 1910. Pp. 243. Price 3*s.* 6*d.*—In noticing the first edition of this book we were able to speak very favourably of it, and this second edition is an improvement even on the first. A number of extracts from scientific works have been added, and we are glad to see that the small error we pointed out has been corrected. The importance of German as a language for all who study science can hardly be over-estimated, and no student can wish for a better introduction to scientific German than is provided by this book.

Fly-leaves from a Fisherman's Diary. By Captain G. E. SHARP. London: Edward Arnold. Pp. 175. 1910. Price 5*s.*—Fishing as a recreation is so much in vogue among medical men that in recommending this little book in our columns we are addressing many who know already how to throw a line and are sensible also to the keen yet soothing delights of the art. Captain Sharp's book is not a guide to the beginner; it appeals to those who are able to criticise the methods of a dry-fly man, but who yet are not above taking practical hints from one who is an expert in the process of getting fish, which some men who fish a great deal are not. It is an impulsive book, written obviously because the writer felt that it was almost his duty to try to communicate to others some of the "golden glamour which surrounds fishing as it does no other sport"; and being written in this spirit Captain Sharp becomes a successful author. In his little idyll he bubbles over with love for the country and all that dwells in it, and lights up the common elements of the river-side, which might otherwise pass unappreciated, with a spirit of phantasy. We assume that Captain Sharp is no poacher, but he is most humanly alive to all the devices of the illegitimate brotherhood; he fishes also in the spirit of the sportsman, with proper self-abnegation in restoring to its natural element the trout which, after a regretful caress, he finds to be below the standard regulation. Would that all sportsmen were equally conscientious! The book is furnished with some pretty photographs of the river and its surroundings by Mr. Parker.

New Inventions.

THE "AUTOFUME."

THIS is a very ingenious apparatus designed for the relief of certain respiratory disorders, and particularly asthma. The use of the "autofume" assumes that the fumes of a medicated paper affords relief to the patient, and the apparatus supplies the sedative fumes automatically and at regular intervals by means of a clockwork "feed." A glance at the accompanying illustration will make the working of the apparatus clear. A clock regulates the movement of the medicated paper between a spool on the right hand side of the apparatus and a night-light on the left side, which is of a special kind, and is provided further with a safe holder. When the paper comes into contact with the flame of the night-light a fume is thrown off, the character of which may be prescribed by the medical man according to the special needs of the patient. The paper burns regularly and uniformly like ordinary "touch paper." The combustion of the paper takes a few seconds and then a lapse of so many minutes follows according to the adjustment which has been made. The speed of the apparatus can be varied according to the size of the room and to the requirements of the patient. Two driving wheels are provided with each machine. One wheel has three spaces cut in the rim and when running at fast speed the paper takes 7½ minutes to reach the flame, burning 12 inches of paper in one revolution, while at slow speed 15 minutes are occupied in the paper reaching the flame. The



other wheel has two spaces cut in the rim, and when running at fast speed the paper takes 7½ minutes to reach the flame, then rests for 4½ minutes, and when running at slow speed the paper takes 15 minutes to reach the flame and rests again for 9½ minutes, bringing 8 inches of paper through in one revolution, or one-third less paper than with the other wheel. It is stated that the machine will work for a full nine hours if required, or it can be put out of action at any moment and restarted again just as quickly. The apparatus which we examined was submitted to us by Messrs. Arnold and Sons of 26, 30, and 31, West Smithfield, E.C., and the "autofume" was invented by an engineer who suffered severely with distressing asthmatic spasm.

WECHSELMANN'S APPARATUS FOR THE INJECTION OF "606."

THE complete success of the use of "606" depends in no small degree on attention to the technique. Already many methods of injecting "606" have been employed, and that devised by Wechselmann has been widely used. The apparatus for employing this method has been made by Messrs. Hirsch and Co., of 18, Lindower Strasse, Berlin N.39, and 236, High Holborn, London. The mode of using the apparatus is as follows. "606" is dissolved by grinding with 1–2 c.c. caustic soda in an agate mortar. A few drops of glacial acetic acid are added to produce a yellow paste, which is thinned by addition of distilled water and exactly neutralised to litmus paper by means of 1 per cent. acetic acid or 0·1 per cent. normal caustic soda. The resulting suspension is taken up by means of a pipette and introduced into the sterilised tube of a centrifuge. After rotation in the centrifuge, the tube is removed and the upper liquid poured off. The yellow deposit remaining in the tube is agitated with physiological saline solution and poured into a porcelain basin from which it can be drawn through the cannula into the syringe. The required amounts of distilled water and physiological saline solution should be *poured* out from the bottles into the two porcelain dishes. It is not advisable to insert the pipette into the liquids in the stock bottles, as, having once been in contact with the yellow paste, it is naturally apt to make the liquids turbid.

THE LANCET.

LONDON: SATURDAY, DECEMBER 10, 1910.

Pellagra Investigation.

IN the early part of the present year a committee of pathologists and epidemiologists was formed for the purpose of investigating the causation of pellagra,[1] and at a meeting in February it was resolved that Dr. L. W. SAMBON'S hypothesis—viz., that the disease was possibly due to a protozoal organism gaining access to the human body by means of some biting fly—should be investigated; an appeal was then made for the necessary funds. Dr. SAMBON proceeded to Italy in March, and recently presented an interim or progress report[2] on his researches. He claims to have established: (1) that pellagra is not due to the eating of maize, either sound or deteriorated, as hitherto almost universally believed; (2) that it has a striking, peculiar, and well-defined topographical distribution; (3) that its endemic foci or "stations" have remained exactly the same in many places for at least a century; (4) that its stations are closely associated with streams of running water; and (5) that a minute blood-sucking fly, of the genus Simulium, is in all probability the agent by which pellagra is conveyed. He has not been able to carry out the experimental work necessary to prove the agency of Simulium in the transmission of the disease, but has brought together a body of evidence sufficiently powerful, as he believes, to render it almost a certainty.

The various theories at present held as to the causation of the disease, generally connected with maize consumption, are stated, and dismissed as insufficient; there is no difficulty in this, because it is now known that the disease has been repeatedly observed in places where maize is neither grown nor eaten, and in persons who have seldom or never partaken of it. CASANA has stated this to be the case in Spain, and numerous instances are quoted by Dr. SAMBON from different provinces in Italy. It has, however, been claimed by the Italian supporters of the maize theory, the "zeists," that great benefit has resulted from the law of 1902, which (*inter alia*) prohibited the importation of damaged maize, and ordered that poor persons affected with pellagra should be given free meals for not less than 40 days twice a year. Professor G. SANARELLI, now Under-Secretary for Agriculture, reported in 1909 that the number of "pellagrins" within the kingdom had been reduced to barely 55,000 in 1905, showing a decrease of 17,000 in the previous six years; and that the deaths from this cause had fallen from 10,284 in the three years 1887-89 to 4649 in the three years 1906-08. Dr. SAMBON disputes the inference: there has certainly been a diminution in the general death-rate from the disease, but he points out that this has been in progress ever since 1898, long before the law was enacted. In Lombardy and Venetia, the two regions most affected, the number of pellagrins enumerated has dropped from 36,630 and 55,881 respectively in 1881 to 15,746 and 27,781 respectively in 1905. This is certainly a most remarkable and satisfactory improvement. But Dr. SAMBON points out that "one cannot exclude the intervention of new beneficial economic and social conditions known to all, which may have influenced the sanitary conditions of their populations" (these being Professor SANARELLI'S own words in 1907). On the other hand, in Umbria and the Marches there has been an increase from 872 to 4250 in the former region, and from 406 to 1436 in the latter; the disease is also extending in Tuscany and in Latium. Certain defects in administration are pointed out which would certainly seem to interfere considerably with any material improvement from the measures adopted. For instance, in the *locande sanitarie*, for the reception and feeding of patients, Dr. SAMBON states that in some not one-third of the inmates could be looked on as true pellagrins, and as a rule not one showed acute manifestations of the disease. As to the free issue of salt to poor pellagrins, Dr. SAMBON says that "it has not proved more effective in the prevention of pellagra than the capturing of birds."

Dr. SAMBON came to the belief that pellagra was a parasitic disease because of (1) the recurrence of the symptoms, notwithstanding removal from an endemic district; (3) its peculiarities of distribution and incidence; and (3) its symptoms, course, and morbid lesions. He considered it to be an insect-borne disease, because it is not contagious, cannot be accounted for on any food or water theory, is limited to rural districts, has special seasonal incidence (spring and autumn), and is practically restricted to one class of people—the field labourer. Some species of Simulium appeared to be the most likely carrier, affecting the same topographical conditions, and having the same seasonal incidence in the imago stage, and geographical distribution. Dr. SAMBON criticises the maps that have been published showing relative incidence of the disease, and asserts that they have been compiled from data not always comparable and often inaccurate. As a result of his own observations, he states that pellagra localities are, as a rule, "the narrower valleys of hilly and wooded country, trenched by swift-running streams infested with Simulium." He emphasises "streams of running water." Such, however, are not the conditions in the Landes of France, about Arcachon and elsewhere, where centres of pellagra have long existed. Dr. SAMBON also mentions its prevalence in the flat country about Padua, and in the Euganean Hills, a volcanic group noted for the scarcity of water. Later on he states that he invariably found pellagra to be present in "low, flat, or hilly, well-watered areas," but to be absent from "more or less massive mountainous areas."

Several points come out clearly from the report. One is the permanency of the endemic areas, as proved by records, there being practically the same disease distribution now as in past years; another is that towns are entirely exempt from the disease; a third is its practical limitation to field labourers, though occasionally found in prosperous farmers.

[1] See THE LANCET, Feb. 5th (p. 408), and Feb. 12th (p. 450), 1910.
[2] Progress Report on the Investigation of Pellagra. Bale, Sons, and Danielsson, 1910.

Although chronic in its course, pellagra is prone to recrudesce yearly, either in the spring or autumn or at both seasons; the earlier the warm weather sets in the earlier the pellagrous rash appears. With regard to contagiousness, most authors have denied it, and in Italy opinion is almost, though not quite, unanimous against it. According to Dr. SAMBON'S view, which agrees with the facts, the disease is not transmissible in places devoid of the insect carrier, but in endemic centres where Simulidæ are found it is highly infectious. As to the connexion with some species of Simulium, Dr. SAMBON has not been able to ascertain anything definite; neither has he or any other observer detected any parasite in the blood that might be considered the specific cause of the disease, which may be, as he suggests, some ultra-microscopical germ. It is the fact, however, that "*Simulium* is found, and abundantly found, in all pellagrous districts throughout Italy." We think that most will now admit that the maize theory is disposed of, and that Dr. SAMBON'S view furnishes, at any rate, a very good working hypothesis to go on in regard to preventive measures; meanwhile, hæmatology appears to be the field that requires to be worked over, as has been the case in malaria and sleeping sickness. Our acknowledgments are due to Dr. SAMBON for his zeal and labours in the field of preventive medicine, which indicate the direction of further advance.

Cranio-Cleido-Dysostosis.

IT is one of the most noteworthy facts concerning the development of much of the modern progress of anatomy, that a very great deal of what is most suggestive and helpful has come from the observations of clinicians, rather than from the investigations of systematic anatomists. The reason for this is not far to seek. The clinician in his study of the living, and in his comparison of long series of cases showing the effects of disease or the results of imperfect development, has gone back in his methods two centuries behind the modern specialised anatomist. He has returned to the methods of the physiological anatomist—the man who studied structure only as the handmaid of function, and who saw in the responsive living, rather than in the unresponsive dead, the true meaning of the myriad structural peculiarities of the human body. Pure descriptive anatomy must cease to be the sole stock-in-trade of the anatomist if he is to take his proper share in the advancement of his subject.

A recent contribution[1] towards the solution of vexed anatomical problems comes from Mr. D. C. L FITZWILLIAMS, who has had the daring to tackle one of the debated points of morphology most dear to the heart of the anatomist, and who has embarked on the enterprise armed with the knowledge gained by a careful analytical investigation of the recorded cases of cranio-cleido-dysostosis. This disease is a rare one, but its very peculiarity has made its literature somewhat extensive, and Mr. FITZWILLIAMS has been able to collect and tabulate 58 cases from published records, while he has added two cases of his own. His material is therefore sufficient to justify him in drawing conclusions as to the disposition of the characteristic lesions. Since the main features of the condition are seen in the failure of the proper development of the membrane, or dermal, bones, it is obvious that the examination of a long series of cases should furnish an index to the extent to which dermal ossification enters into the general make-up of the skeleton or into the composition of certain compound bones. The development of the membrane bones of the vault of the skull naturally suffers in this disease; but, as its name implies, the clavicle also shares in the dysostosis, and here the greatest anatomical interest in the condition lies. It is in connexion with the degree of maldevelopment of the clavicle that Mr. FITZWILLIAMS has done such good service in making some obscure points of morphology more clear. The question of the development of the clavicle has long been a vexed one. Is the clavicle developed in membrane, or in cartilage; and is it a bone added to the shoulder girdle, or is it a primordial bone, and one of the intrinsic elements of the primitive pectoral arch? These are the questions upon which, for long, anatomists have ranged themselves into different camps. GEGENBAUR has maintained that the clavicle is a dermal bone, which therefore cannot be regarded as a real part of the primitive girdle; but HOFFMAN and GOETTE have claimed the clavicle as primordial. The question is one on which opinion is likely to be divided when it is derived from a study of the development of the bone, for the ossification takes place so early, and is of such a hurried nature that observations on its exact sequence are necessarily difficult. The secondary question as to what part of the primitive shoulder girdle the clavicle represents, if it is in truth a primordial bone, has received as many answers as there are primitive parts to which to assign it. Upon the question of the ossification of the clavicle the study of cranio-cleido-dysostosis might be expected to throw much light; if it is a dermal bone its development will suffer, but if it is a cartilage bone its development may be expected to be found but little modified. In the series of cases collected by Mr. FITZWILLIAMS it was found that the condition most commonly met with was that the sternal end of the bone was present in some degree, but the acromial end was absent. This is a highly suggestive condition, for there are several anatomical distinctions between the two ends of the clavicle, and a partial demarcation is to be seen at times in the presence of vascular or nervous foramina. In those cases in which the outer extremity of the clavicle is undeveloped, it is generally found that a ligament continues the inner portion of the clavicle towards the scapula; but the curious fact about this ligament is that it does not replace the absent outer third of the bone and run to the acromion; but it becomes, as a rule, attached to the coracoid process. Two elements are therefore indicated in the clavicle, the older cartilaginous portion from the sternal end to the coracoid process, represented in the adult bone by the inner two-thirds of the bone and the coraco-clavicular ligaments; and a new and separate dermal ossification for the flat acromial end which stretches from the ligaments outwards to the acromion.

So much—and morphologists will allow that it is a great deal—the study of this interesting disease has yielded. For the rest Mr. FITZWILLIAMS maintains, and certainly correctly, that the basal centre of the coracoid process has the oldest

[1] See THE LANCET, Nov. 19th, 1910, p. 1466.

philogeny, and that by entering into the formation of the glenoid fossa it declares itself to be the true coracoid element of the pectoral girdle. This is the view that was maintained by the late Professor G. B. HOWES and substantiated by SABATIER. But this portion of the coracoid undoubtedly forms an anatomical continuity with the ligamentous bridge which continues the sternal end of the clavicle in cases of cranio-cleido-dysostosis, and therefore Mr. FITZWILLIAMS is probably correct in assuming that the whole continuity of this bar—the base of the coracoid, the coraco-clavicular ligaments, and the inner two-thirds of the clavicle—are the human representatives of the old coracoid element of the primitive pectoral girdle. There are obviously two elements combined in the human coracoid process, and the other element, which is represented by the free extremity, should correspond to the precoracoid element of the primitive girdle; and this element Mr. FITZWILLIAMS is inclined to continue as the costo-coracoid ligament. The pectoral girdle therefore, as a result of this very interesting investigation, would seem to have resolved itself into some order. The coracoid and precoracoid elements are satisfactorily located in the whole of their extent, and a host of trivial structures have been robbed of the unwarranted importance assigned to them by morphologists who are prepared to see resemblances and remnants in any and every trifling structure which happens to exist in the area in which some more important structure appears to be missing. Mr. FITZWILLIAMS will have the support of all anatomists in relegating the centres of ossification for the tip of the coracoid process to the class of "traction epiphyses" of PARSONS, for their development in connexion with the muscular origins should have been pointed out in the text-books of anatomy long ago. To the anatomist this paper will come as a lesson that it is not by any means only among the dead in the dissecting-room that the secrets of morphology are to be learned; we have ourselves published several papers during the last few months which have done much to make clear to morphologists the meaning of structures concerning which much has been written but little has been known.

Recent Studies in Epidemic Poliomyelitis.

WE have received a reprint of an interesting paper, published in the *Journal of the American Medical Association* of Sept. 24th, by Dr. SIMON FLEXNER of the Rockefeller Institute for Medical Research, under the title of "The Contribution of Experimental to Human Poliomyelitis." The suggestion that infantile paralysis might be a contagious disease was mooted more than a quarter of a century ago, and evidence in favour of this contention, both epidemiological and experimental, has accumulated and now resulted in complete demonstration. Dr. FLEXNER'S paper gives a most valuable and lucid summary of his own and other investigators' work upon this important question. Before 1907 epidemic poliomyelitis was rare in the United States, but since that year it has become widely distributed. It appears that before 1907 the disease had been increasing in frequency in Northern Europe, more especially in Scandinavia, where attention was early attracted to its investigation, and where the important work of WICKMAN laid the foundation of the recent advances. WICKMAN collected some closely allied conditions together under the generic term of Heine-Medin's disease, a name which is now extensively used in Germany. Recent studies in Scandinavia have shown that the contagion may be conveyed from the sick to the healthy by intermediaries, who are themselves healthy but act as carriers, and that the incubation period is a very variable one, ranging from 2 to 20 days, the average being from 8 to 10. Dr. FLEXNER states that in 1907 a pandemic of the disease arose, and that the United States, Austria, Germany, and France have been visited by epidemics since that date. In regard to the American cases, it is suggestive that the original outbreaks of the epidemic in the summer of 1907 occurred along the Atlantic seaboard, particularly about New York and Boston, which constitute the two main channels of entry of the immigrant streams from Northern and Eastern Europe. It is also highly significant that the second large isolated outbreak occurred about Minnesota, to which considerable numbers of immigrants from Norway and Sweden proceed.

Although the infectious nature of poliomyelitis has been suspected for so long, attempts to isolate the causal agent have until recently failed entirely or yielded organisms which subsequent research has proved to be due to contamination or to secondary infections. The recent epidemic spread of the condition, more especially during 1909, led to widespread activity in research in several countries in regard to this disease, with the result that almost simultaneously Dr. FLEXNER and Dr. PAUL A. LEWIS in America and LANDSTEINER and LEVADITI in France described an extremely minute or ultra-microscopic organism as the infective agent. It is this discovery which has proved of such interest and value in regard to our knowledge of this disease. Dr. FLEXNER describes the failure of the earlier attempts made by Dr. LEWIS and himself to transfer poliomyelitis from human beings to monkeys by the inoculation of fluids removed at different stages of the disease through lumbar puncture. It was not until September, 1909, that they were enabled to try the effects of the direct injection of an emulsion of the spinal cords of two fatal cases of the disease into the brain of monkeys, a procedure which was followed by paralysis after an interval of some days of perfect health. During the summer of the same year LANDSTEINER and POPPER also succeeded in inoculating monkeys with the spinal cord of a fatal case, but they made their inoculations into the peritoneal cavity and did not succeed in transferring the disease to other monkeys, whereas Dr. FLEXNER and Dr. LEWIS by their method were successful in transmitting the virus from monkey to monkey. The characters of the virus, so far as they have yet been discovered, are as follows: it is of very minute size and passes readily through the pores of the finest and densest porcelain filters, such as the Chamberland or Berkefeld. It thus belongs to the group of filterable viruses. It is not yet certain whether the virus has been seen. On examining under the dark field microscope an aqueous suspension

obtained by filtering an emulsion in distilled water of the spinal cord of an infected animal, bright dancing points devoid of definite size and form, and not truly motile, can be seen, but it is by no means established that these particles are the micro-organisms of poliomyelitis. The filtrates from such emulsions are very potent and very small quantities are sufficient to induce paralysis when injected into the brain of monkeys. The virus also appears to be highly resistant; it withstands glycerination for weeks or months, and also shows little reduction in potency after drying over caustic potash for weeks. If kept frozen at from 2° to 4° below 0° C. it retains its virulence for weeks, but it is destroyed by heating for half an hour at temperatures from 45° to 50° C. It can also be destroyed by 1 per cent. hydrogen peroxide solution, or by menthol. It is still not certain whether the virus has been cultivated outside the animal body on culture media, although there are some results which suggest that this is possible.

Observations made on the experimental disease in monkeys have resulted in some important additions to our knowledge of the pathology and morbid histology of the disease. The incubation period elapsing between inoculation and the onset of paralysis has varied from 3 to 33 days, the average being eight or nine. In regard to the symptoms, there is a striking similarity with those occurring in the human disease, both in regard to the severe cases and the abortive or evanescent attacks which occur during epidemics of the disease. The mortality among the inoculated monkeys is, however, much greater than that of the human cases, for whereas the death-rate in epidemics in man rarely exceeds 10 per cent., of the inoculated monkeys at least 50 per cent. died. The lesions found after death show very close correspondence with those hitherto observed in fatal cases in man. The changes are more marked in the spinal cord than in the brain, and are more pronounced in the grey matter and membranes than in the white matter. The meninges show diffuse infiltration with round cells, especially about the blood-vessels, of which the adventitial coat is alone involved, although the lumina of the vessels may be lessened by compression. The meningeal cellular infiltration does not lead to exudates on the surface, and is almost exclusively composed of mononuclear cells. The anterior and posterior horns of the grey matter are affected, the anterior more markedly. There are cellular infiltration and œdema of the perivascular spaces, and there may be hæmorrhages. The nerve cells undergo degeneration and necrosis. Changes of similar character but of slighter degree may occur in the white matter, in the brain, and in the intervertebral ganglia.

The pathogenesis of the affection appears to be that the virus gains access to the leptomeninges, setting up cellular infiltrative changes, more especially in the perivascular lymph spaces of the arteries entering the cord and medulla. These vascular lesions and their distribution determine the severity and degree of the involvement of the nervous tissues, and therefore also the extent and distribution of the clinical manifestations. The preponderating character of the lesions in the anterior horns is accounted for by the severe implication of the central arteries entering by the anterior median fissure, and the greater richness of the blood-supply to the cervical and lumbar enlargements explains their liability to severe lesions. Some interesting experiments were carried out to determine the possible modes of infection. Inoculation can be effected with greater or less success by various channels—viz., intracerebral, intraperitoneal, by subcutaneous injection, by injection in large nerves, and by some mucous surfaces. Certain theoretical considerations have led Dr. FLEXNER and Dr. LEWIS to suspect the naso-pharynx of being a common portal of entry of the virus in the human disease; they therefore endeavoured to put this question to the test in the experimental infection of the monkeys. They found that the mucosa of the naso-pharynx was readily permeable by the virus, leading to infection and paralysis. They also bring forward evidence which seems to indicate strongly that the nasal mucous membrane may not only be the channel of entry of the virus, but that it may also be a channel of elimination whereby the virus becomes spread externally. Investigation of the cerebro-spinal fluid by lumbar puncture shows that the number of cells it contains becomes progressively increased shortly after infection and before paralysis supervenes, with the result that the fluid becomes opalescent and may coagulate spontaneously. There is also an excess of protein as shown by NOGUCHI'S butyric-acid test. This cellular reaction is not purely lymphocytic since it includes the polymorphonuclear leucocytes early in the disease. These conditions do not last long, but are soon succeeded by a stage in which the fluid is clear, non-coagulable, and does not contain an excess of protein, while the lymphocytes alone are increased. Dr. FLEXNER suggests that these observations may prove to be of value in the early diagnosis of the human cases, if systematic examination be made of the cerebro-spinal fluid in epidemics of the disease.

The question of the production of immunity to the virus of poliomyelitis has also been studied by Dr. FLEXNER and Dr. LEWIS, and although their experiments have not as yet yielded a practical method applicable to man, yet they show that an artificial immunity can be developed, and they hold out hope for the future. They find that an undoubted attack of poliomyelitis, even when not accompanied by paralysis, produces a condition in which the monkey is refractory to re-inoculation. A condition of active immunity may also be induced by subcutaneous injection of the virus, either crude or modified by various reagents. It has also been shown that in the blood, both of human beings and of monkeys who have recovered from an attack of poliomyelitis, there exist neutralising principles for the virus. Experiments are in progress with the object of endeavouring to produce a serum for use in the treatment of the disease. We have said enough to show how important Dr. FLEXNER'S work is. It is impossible not to admire the remarkable energy and assiduity implied by the acquisition of such important results within the space of one year, while the direct and practical manner in which the problems have been attacked offers an admirable model for the scientific study of diseases of obscure pathology.

Annotations.

"Ne quid nimis."

THE MEDICAL FACULTY OF THE UNIVERSITY OF LONDON.

A MEETING of the Medical Faculty was summoned by the Vice-Chancellor of the University for Friday, Dec. 2nd. Only 29 members attended, and as a quorum is 30 the meeting could not be held. This is the fourth time in succession that a failure of meeting has resulted owing to the non-attendance of a sufficient number of members. The meeting convened for the 2nd inst. was for the purpose of electing or re-electing a dean. The faculty is therefore still without a chairman. This apathy on the part of those comprising the faculty is greatly to be deplored.

THE STETHOSCOPE.

IN his new volume, "Rewards and Fairies," Mr. Rudyard Kipling reintroduces the magical machinery which produced such a charming collection of ancient silhouettes in "Puck of Pook's Hill." The new series of ghosts of the past include Laennec and Nicholas Culpepper, the great herbalist. René Théophile Hyacinthe Laennec was born in 1781 in the beautiful old Breton town of Quimper, and on the north side of the noble cathedral stands his statue. Laennec was a surgeon in the Republican army in 1799 and served in the Morbihan. Mr. Kipling's sketch of the father of auscultation has charm and interest, and if he has taken liberties with facts we do not suggest that he has exceeded the romancer's licence. If we accept Forbes's careful biography of Laennec implicitly—and it was written immediately after the physician's death, being compiled from such excellent sources as the memoirs by Kergaradec and Bayle, supplemented by notes contributed by Laennec's cousin—the true story of Laennec differs from Mr. Kipling's presentment. From these biographers it seems proved that after 1799 Laennec was occupied in Paris at the clinic of La Charité, and up to 1818 was busily engaged in a constant output of important writings. In 1818 he broke down in health, probably from incipient phthisis, to which he ultimately succumbed in 1826. In 1821 he returned to Paris and resumed his post on the staff of the Necker Hospital. Mr. Kipling represents him as a prisoner in England at some date subsequent to the battle of Assaye, and describes him as experimenting with wooden stethoscopes (shaped liked trumpets) in a Sussex village. Laennec in his great treatise describes vividly his first use of an impromptu stethoscope, which consisted of a roll of paper, and the incident, he states carefully, occurred in 1816. The early history of the stethoscope is on the whole well authenticated. In the introduction to Laennec's "Diseases of the Chest" (second edition, 1826) various kinds of materials are mentioned as employed by the discoverer—paper, wood, glass, even goldbeater's skin—but they all had a cylindrical form, and there remains no doubt as to the final shape in which Laennec left the stethoscope, a cylinder of wood 1½ inches in diameter and 12 inches long, perforated by a bore three lines in diameter, and hollowed out at one end into a funnel-shaped cavity of the same depth as the external diameter of the cylinder. The late Sir George Burrows rescued from the wards of St. Bartholomew's Hospital the remains of such an instrument, which had been the property of Dr. Bond, afterwards Regius professor of medicine at Cambridge. Burrows and Bond were two of the first to study auscultation at St. Bartholomew's, when they were serving as clerks to Dr. Latham in 1827. Burrows's instrument had one part missing when it found its way into the Museum of St. Bartholomew's in 1887, and no instrument maker in London could be found capable of restoring it, but a complete example was accidentally discovered at Westerham in Kent by Mr. A. Maude, and this is now in the same museum. The construction of these models corresponds exactly with Laennec's own description.

THE USE OF HYDROCYANIC ACID GAS FOR KILLING RATS AND RAT FLEAS.

EXPERIMENTS have been carried out in the Bombay bacteriological laboratory by Captain W. D. H. Stevenson, I.M.S., with a view of ascertaining the value of hydrocyanic acid gas as a means of killing rats and rat fleas, more particularly in plague-infected houses in India. The results of these researches have been embodied in a preliminary report which is now published as No. 38 of the new series of Scientific Memoirs of the Officers of the Medical and Sanitary Departments of the Government of India. It appears that hydrocyanic acid gas has been of late years largely used in America, Australia, and South Africa for the destruction of insect pests on plants and fruit trees, and also for the "disinfection" of houses, jails, and railway carriages to rid them of vermin. In 1901, when plague was prevalent in Cape Colony, Professor W. J. R. Simpson suggested the use of this gas to cleanse houses infested by bugs, which were then under suspicion of conveying plague infection to man; but though experiments were begun at the time they were not persevered with. Captain Stevenson discusses the action of this gas on plants, animals, insects, food, and fabrics. Its use is not attended with any injury, even to the most delicate plant, rats and mice are readily killed by it, as also are fleas and other insects, their eggs and larvæ being quickly devitalised. Dried grain acquires no poisonous properties when exposed to its fumes, nor is the germinating power affected. Moist foods, on the other hand, such as milk, butter, and flesh, like water, absorb the poison. Unlike sulphurous acid, hydrocyanic acid gas has no deleterious action on metal or textile fabrics, but the fumes do not destroy the plague organisms or other bacteria. Its use, therefore, in connexion with plague is limited to two purposes—firstly, to destroy fleas on the clothing of dirty native travellers and, secondly, to fumigate the interiors of houses to destroy rats and their fleas. So far as the utility of the process for the freeing of clothing from fleas or other vermin is concerned, Captain Stevenson reports favourably upon it and regards it as a very cheap and efficient pulicide. Its use in this direction is, under proper precautions, attended with comparatively little danger to human life. But as regards the disinfection of rat-infested houses by this means the investigator comes to conclusions not so satisfactory. In isolated houses with clear space around them it might, subject to certain necessary restrictions, be usefully employed; but in crowded localities it cannot be safely made use of. The fumes are liable to spread to contiguous houses, and the gas may pass along rat runs from one dwelling to another. There is danger also to those engaged in carrying out the process, and skilled supervision is always essential. The fumes are so deadly that a whiff of fairly strong gas is liable to kill a human being; even a trace of hydrocyanic acid in the air that is breathed causes headache and nausea. It is recorded by an expert, as to an experiment conducted in America, that persons walking 100 feet away from the building that was being fumigated could detect the odour of the gas. The faint almond smell of the fumes and the taste at the back of the throat are only appreciated for the first few moments, the sense of smell and taste being seemingly paralysed by the diluted gas after the first few whiffs. Captain Stevenson, however, describes a delicate

test which can be applied to the air by those engaged in the process of fumigation before the room is re-entered; and if this test be applied the danger to the operators would seem to be much reduced. Further reports are likely to be issued; but so far as our present knowledge goes we fear that the possible dangers associated with the employment of hydrocyanic acid gas for the fumigation of the interior of houses are likely to prevent its use, save in exceptional circumstances. Like carbon monoxide, the risks to human life connected with its employment for destruction of rats and fleas would seem to be too great to permit of its general adoption.

SPONTANEOUS DISLOCATION OF THE HIP FOLLOWING ACUTE INFECTIOUS DISEASES.

SPONTANEOUS dislocation is a rare sequel of infectious diseases. In the *Boston Medical and Surgical Journal* of Nov. 3rd Dr. Charles Greene Cumston has reported the following case. A healthy girl, aged 9 years, had a severe attack of scarlet fever in March, 1910. She was in bed six weeks. When she began to walk in the latter part of May it was noticed that she had a decided limp and that the right leg was shorter than the left. She came under observation on the 27th. She was a well-developed girl with excellent muscles. The right leg was 4 centimetres shorter than the left and in a position of marked adduction with internal rotation. The movements of the hip-joint were much limited, rotation and flexion being almost absent. The trochanter major was 4 centimetres above Nélaton's line. There was no pain on pressure. Iliac dislocation of the femur was diagnosed. To reduce the shortening and to improve the position of the limb extension was carried out for five weeks with little or no improvement. Reduction was attempted under narcosis on July 3rd. After much manipulation the head of the bone was got into the acetabulum. A plaster cast was applied and the limb was placed in abduction with extension until August 17th, when the cast was removed. The joint was in good condition, but there was muscular atrophy. Electricity and massage were applied, and on Sept. 2nd the functions of the limb were perfectly restored. The hip is much more often the seat of spontaneous dislocation than any other joint. Of 80 cases collected by Degez, the hip-joint was involved in 74, the knee-joint in 2, and the ankle-joint in 1. Dr. Cumston suggests that this greater frequency of dislocation of the hip may be due to the youth of the patients, because the hip-joint has a great tendency to the development of pathological processes in early life. Of 90 cases, the patient was over the age of 20 years in only 11. The dislocation was iliac in 80, obturator in 6, and perineal in 1. By far the most important causes of spontaneous dislocation are typhoid fever and articular rheumatism. Then, in order of frequency, follow scarlet fever, influenza, small-pox, gonorrhœa, erysipelas, and puerperal fever. In typhoid fever the dislocation usually occurs during convalescence, but in articular rheumatism and scarlet fever during the progress of the disease. The pathogenesis of spontaneous dislocation has always been a puzzle. J. L. Petit, who in 1722 first described the condition in his famous work on dislocations, attributed it to effusion of fluid into the joint, which distended the capsule and caused softening and laxity of the ligaments, and finally pushed out the head of the bone. In a number of cases hydrarthrosis has been found on operation. But whether effusion alone is sufficient to produce dislocation is not certain. Verneuil and Reclus endeavoured to explain spontaneous dislocation by abnormal muscular contraction with paralysis and atrophy of antagonists. Kummer has pointed out that slight trauma probably plays a part. This is borne out by the fact that in several cases the dislocation occurred whilst the patient was being transported from one bed to another. The morbid anatomy has recently been studied. The capsule is only softened and distended, in contrast to what occurs in traumatic dislocation, where it is always ruptured. The nature of the contents of these joints has been the subject of much discussion. Hueter believes that all spontaneous dislocations of the hip are due to purulent infection, but serous or sero-fibrinous fluid has been found. The surfaces of the joint are only slightly changed, and in many cases have proved to be normal. On the other hand, marked changes have been observed. Cartilaginous growths have been found on the head of the femur during arthrotomy, and the cartilage covering the acetabulum has been sometimes eroded. If the dislocation is not soon reduced the joint cavity quickly becomes filled with connective tissue. Muscular atrophy and contraction have been found in a number of operations. Spontaneous dislocation is usually first discovered when the patient begins to walk. If discovered early, it can frequently be reduced. Otherwise reduction is difficult or impossible in consequence of the anatomical changes. The treatment should, in the first place, be preventive. If in fevers there has been a faulty position of the limb for some time, dislocation should be looked for when the patient is about to leave his bed. If permanent flexion or adduction occurs placing the limb in a correct position may prevent dislocation. If dislocation has occurred it should be reduced. If this is impossible the limb should be placed in the best position. If reduction cannot be performed by manipulation an open operation may be necessary.

THE MEAT-SUPPLY AT SMITHFIELD MARKET.

Dr. William Collingridge, in his tenth annual report to the Corporation of the City of London, which we have already reviewed at some length, presents some figures as regards meat-supply at the Central Meat Market, Smithfield, which make instructive reading at the approach of Christmas. It is pointed out that owing to the diminishing supplies from the United States the carcass butchers have been compelled to turn more attention to the English produce. It seems, however, that the uncertainty of the supplies from foreign countries, notably, perhaps, the Argentine Republic, will always prove a disturbing factor in the continued sale of home-grown produce, a fact which was so markedly illustrated in the Christmas of 1909. The effect of the Foreign Meat Regulations has resulted in the Dutch meat bearing the label of the Dutch examining officers, and it is reported that there is an evident desire on the part of the authorities to conform to the English requirements. The Danish meat is apparently going largely to Germany, and England can only have it when the Fatherland does not want it. With respect to the supply of cattle imported alive to Deptford, where it is killed, the report shows that the ever-increasing population of the United States holds out prospect that before many years have passed the Americans may cease to export their cattle to this country, and this fact may explain the activity of the Americans in developing their works in Argentine. Whatever may be the explanation, the fact remains that our live-cattle supplies from the United States and Canada are steadily falling and in 1909 there were but 205,000 bullocks from the States and 113,000 from Canada, while the imports of refrigerated beef from the United States are now only about one-third of what they were four years ago. But the compensating influences are already showing themselves, and the year 1909 witnessed the first arrival of chilled beef from Australia. Apparently this meat was not all of first-class quality and it showed much variety as

regards size. The length of transit was 62 days, the meat being preserved by sterilising the air of the meat chamber on the "Linley" system. There was also a considerable increase of frozen meat from New Zealand, Argentine, and Australia.

PHARYNGEAL PITUITARY BODY.

THE wide interest now taken in acromegaly has given rise to many recent investigations into the origin and nature of the pituitary body. As is well known, the glandular part of the pituitary arises as an outgrowth (Rathke's pocket) from the primitive mouth of the embryo. When the base of the skull is developed the stalk of the outgrowth is separated from the body of the gland and was supposed to completely disappear. In 1888 Killian observed that a small mass of pituitary tissue may be found in the naso-pharynx. Last year Dr. W. Haberfeld[1] showed that this small mass of pituitary tissue is constant in the human naso-pharynx, and represents part of the stalk of the pituitary outgrowth. The pharyngeal pituitary lies in the submucosa of the pharynx immediately behind the septum of the nose. The mass is of small size, about the size of a grain of rice. It is in close relationship with the tonsil of the naso-pharynx. At the last meeting (Nov. 25th) of the Anatomical Society of Great Britain and Ireland Mr. J. E. S. Frazer of King's College, Strand, showed by means of models and diagrams that the stalk of the pituitary outgrowth becomes associated during development with the posterior border of the nasal septum, down which it extends for a considerable distance. A specimen which Mr. A. R. Tweedie of Nottingham recently presented to the Museum of the Royal College of Surgeons of England also throws light on the relationship of the pituitary to the septum. The specimen shows part of the head of a child who lived for some weeks. The infundibulum of the pituitary extends into the posterior border of the septum of the nose, on which the pituitary body forms a tumour-like mass. The tumour was observed during life through a cleft in the palate, but fortunately no attempt was made to remove it.

THE TOXIC EFFECTS OF ASCARIDES.

IT has long been known that ascarides possess a repulsive irritating odour which becomes more marked after section. This odour, which has been described as pepper-like by von Linstow, produces marked toxic effects upon certain persons. These effects form the subject of an interesting note in the *Münchener Medizinische Wochenschrift* of Sept. 20th by Professor R. Goldschmidt of Munich, who himself is thus affected. He refers to the previous observations on this subject by Miram, Cobbold, Huber, Leuckart, Bastian, Raillet, von Linstow, Arthus and Chanson. Raillet himself suffered from suffusion of the eyes, sneezing, nausea, and swelling of the finger after section of some ascarides. Arthus and Chanson observed similar symptoms in three persons after dissecting these worms. They also showed that the cœlomic fluid of ascarides when injected into rabbits in doses of 2 cubic centimetres sufficed to produce death in ten minutes. Since Professor Goldschmidt found himself susceptible to the toxic effects of these worms he has made inquiries of other workers and been able to collect nearly 20 instances of a like susceptibility. He believes that some persons are permanently immune to these toxic effects and can work at the dissection of these animals with impunity. As a rule, however, most people suffer at first in only a slight degree, but the severity of the symptoms increases progressively with repeated attacks, so that several workers among Professor Goldschmidt's cases stated that they had been obliged to give up working at this subject owing to this cause. Professor Goldschmidt himself has now become so sensitive to this irritant that it is only necessary for him to go near where one of his students is working at the dissection of an ascaris to get severe symptoms, and it has now become a physical impossibility for him to work with this worm. The symptoms vary in individual cases. The most common are irritation of the eyes, leading to conjunctivitis and lacrimation. Other persons commence with sneezing, which goes on to a chronic naso-pharyngeal catarrh. Later stages may be those of catarrh of other mucous membranes, with troublesome cough and with asthma. Professor Goldschmidt suffers with severe attacks of asthma occurring every night for a week, these attacks appearing at the same time each night with great regularity, a fact also observed by Bastian. Some persons are highly susceptible, so that even the first attempt to work with these worms causes severe or even alarming symptoms. If any of the body fluid of the ascaris comes in contact with a sensitive surface, such as the conjunctiva, severe inflammation rapidly develops, and sometimes, as already mentioned in Raillet's case, the hands may swell. The ascaris megalocephala of the horse is much more irritant in its effects than the ascaris lumbricoides of man, a fact noticed long ago by Bastian, who was himself sensitive to the former but not to the latter worm. The nature of the substance leading to these symptoms is as yet uncertain. Weinland has shown that free valerianic acid is one of the end products of metabolism of these animals, and has suggested that this is the causal agent, a suggestion which Professor Goldschmidt does not accept. These observations are of considerable interest, since it is known that the emanations from some other animals may lead to attacks of asthma in susceptible persons, and Dr. Marcus, a colleague of Professor Goldschmidt, who suffers from the toxic effects of ascarides, points out the analogy of the symptoms with those of hay fever.

[1] Beiträge zur Pathologischen Anatomie, 1909, vol. xlvi., p. 133.

EARLY OPERATIONS FOR CATARACT IN FRANCE.

AT a meeting of the Société d'Ophtalmologie de Paris this autumn M. Terson made some observations on the operation for cataract as performed during the first half of the nineteenth century in France, and exhibited a painting which he had found in one of the rooms of the Musée Carnavalet, of which a reproduction is given in the October number of *Recueil d'Ophtalmologie*. This represents the results of an operation for cataract by Dupuytren at the Hôtel Dieu in presence of Charles X. in 1825. In the picture discovered by M. Terson the King with a group of officers are being conducted by M. Dupuytren through one of the wards of the Hôtel Dieu, and a patient on whom the great surgeon has operated has been unbandaged and is being told to look at His Majesty. She is holding up both hands in charmed surprise at the recovery of her vision. A Sister of Mercy and some surgeons and students are in attendance. The celebrated surgeon shows the triumph, complete and certain, of this surgical operation: little pain, no blood, and, it may be added, no vitreous humour. For it is evident that, although only 50 years after Daviel, it is not his extraction that has been executed. Dupuytren preferred depression to extraction; experience had shown him that the results of depression were more advantageous, and we find in his writings the statement, somewhat audacious, that this operation diminishes danger in proportion to the frequency with which it is repeated in the same individual. Few surgical proceedings are more interesting to follow than the vicissitudes of extraction during the first half of the nineteenth century. Undoubtedly following Daviel, a pleiade of eminent oculists, Pamard, Pellier, and so many others, the proceedings of which may be found

described and considered in the Cours d'Opérations de Pellier de Quengsy, established the supremacy of extraction. Some, nevertheless, depressed or extracted according to their view of the nature of the case. Then reaction took place, and the predecessor of Dupuytren at the Hôtel Dieu, Pelletan, considered the method by displacement was applicable to the larger number of cases. A little after Scarpa, Langenbeck, and others the fear of accidents led most surgeons to use the needle. Sanson and Gosselin appeared to consider the escape of the vitreous humour as one of the ordinary results of extraction. Demours considered extraction to be preferable when there was no contrary indication. Roux, a very skilful operator, considered depression as quite an exceptional operation. Velpeau held that if the dangers of extraction were more serious and more apparent, those of depression were more numerous and more real. Sichel himself was by no means an exclusive partisan of extraction, and maintained that the indication for the two methods depended on the nature of the cataract. Nélaton and Sédillot, with some restrictions and hesitation, recommended extraction generally. About 1865 depression was still practised by certain surgeons, as by Jüngken at Berlin, but depression, in accordance with De Graefe and his school, was almost entirely given up. It may be said, then, that whilst depression modernised by preliminary iridectomy may be found occasionally indicated, extraction has been preferentially performed by all the great ophthalmologists and by the larger number of great surgeons.

THE TREATMENT OF ULCERS OF THE LEG BY A PASTE OF GELATIN, GLYCERINE, AND ZINC OXIDE.

IN the *University of Pennsylvania Medical Bulletin* for October Dr. B. A. Thomas advocates the treatment of varicose ulcers of the leg by a paste of gelatin, glycerine, and zinc oxide as superior to all other methods. It may be remembered that this paste was introduced some years ago for the treatment of certain skin diseases, particularly eczema, by Dr. Unna of Hamburg, and has attained a considerable reputation. It does not appear to have been used by him for the treatment of ulcers of the leg, but several American surgeons, of whom it is not certain which can claim priority, employed it. The treatment, however, has failed to arouse the interest it deserves. From an experience of several years of out-patient work Dr. Thomas is satisfied that it is much superior to any other treatment. The paste is prepared as follows. Two parts of the purest gelatin are dissolved by means of a hot water bath in five parts of water. While the mixture is hot five parts of glycerine and two parts of zinc oxide are energetically stirred in until the whole is cool. In cases complicated by xerodermia, hyperplasia, pruritus, or fœtor Dr. Thomas adds a quarter of a part of carbolic acid. At room temperature the paste assumes the condition of table gelatin and may be preserved for some time. Before application the paste is liquefied in a hot water bath and cooled. In the meantime the leg and foot are thoroughly cleansed with soap and water (preferably tincture of green soap), alcohol, mercury bichloride (1 in 2000 to 4000). or carbolic acid (1 in 40). The ulcer is disinfected with peroxide of hydrogen and a solution of mercury bichloride or carbolic acid. The surface is thoroughly dried and the paste is applied over the whole surface from the metatarso-phalangeal articulations to the tubercle of the tibia. A layer of gauze bandage 3 inches wide is then applied, being cut at intervals to avoid excessive overlapping and wrinkles. Another layer of the paste is applied and a second gauze bandage, and so on until three or four layers of bandage have been applied, finishing with the paste. As the paste is rather sticky a layer of shellac may be applied for fastidious patients. A thin layer of non-absorbent cotton answers the same purpose. In many cases the dressing may be left undisturbed for from two to eight weeks, and when removed the ulcer will be found healed. But it is safer to ask the patient to return in two days. If there is then any evidence of discharge at the site of the ulcer, manifested by saturation of the overlying dressing, the dressing must be fenestrated, the ulcer cleansed, and a dusting powder, such as salicylic and boric acid talcum, supplemented by a simple gauze dressing, is applied. The patient should return twice or thrice weekly for renewal of the gauze dressing. Should the paste dressing become loose from subsidence of the swelling of the leg, it must be removed and a fresh one applied. Dr. Thomas has never found it necessary to scarify, curette, or excise the floor or edges of the so-called indolent ulcer, nor to apply a stimulant or caustic of any kind in order to promote healing. The primary indication in the treatment of varicose ulcer is to support and improve the circulation in the part. The paste dressing does this by furnishing a veritable new skin. It is freely pliable and slightly elastic, contracting somewhat after its application. These qualities cannot be ascribed to the ordinary bandage or even to the elastic stocking. A great advantage is that dressings are necessary only at long intervals, and the period of healing is shorter.

CHOLERA IN MADEIRA.

WE learn from our correspondent in Madeira that there is reason to hope that the invasion of cholera will not prove a lengthy one. The Lisbon authorities were in the first instance not over prompt, for they sent out a bacteriologist to investigate the suspected cases, but made no report upon what he found for a week. The Governor of Madeira then requested the assistance of Dr. Michael Grabham, and the vibrio was found in some abundance. During the six weeks since the first cases came under notice 40 to 50 cases occurred, with 20 deaths, but the authorities are working well, and it is hoped that the invasion has been successfully checked, although the number of cases is now much larger. The Royal Mail Steam Packet Company's steamers will not call at Madeira, outwards or homewards, until further notice.

Mr. Eben Henry Edwards, M.B., C.M. Edin., has been granted His Majesty's Royal Licence to wear the Insignia of the Third Class of the First Division of the Imperial Chinese Order of the Double Dragon, conferred upon him by His Majesty the Emperor of China.

Mr. Sylvanus Glanville Morris, M.D. Edin., has been appointed a Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England.

Dr. Thomas Buzzard has been elected a Foreign Corresponding Member of the Société de Neurologie, Paris.

DEATH OF DR. AUGUSTUS HENRY BAMPTON.—Dr. A. H. Bampton died at his residence, Brookfield, Ilkley-in-Wharfedale, Yorkshire, on Nov. 26th, in his fifty-ninth year, from pneumonia after a short illness. Dr. Bampton was born in Devonshire and was formerly a lieutenant in the Royal Navy. On leaving the service he studied medicine and graduated M.D. and M.Ch. of the Royal University, Ireland, in 1879. After holding appointments at Westminster Hospital and the South Devon and East Cornwall Hospital, Plymouth, Dr. Bampton commenced practice in Plymouth, joining the late Dr. W. Bazeley in partnership. He was formerly assistant physician to the Plymouth Public Dispensary. About 20 years ago Dr. Bampton left Plymouth and practised at Ilkley, in Yorkshire. He was medical officer of health of Ilkley, and surgeon to the Ilkley Cottage Hospital. Dr. Bampton contributed several articles to THE LANCET and other medical journals.

THE LONDON COUNTY COUNCIL AND THE ROYAL COMMISSION ON THE FEEBLE-MINDED.

THE General Purposes Committee submitted to the London County Council on Dec. 6th an exhaustive report, prepared by four or five of the committees most directly concerned, in which the recommendations of the Royal Commission on the Care and Control of the Feeble-Minded were examined in their bearing upon lunacy administration in London. The Commissioners in their report admitted that the position of London in regard to the care of the mentally defective was exceptional, not so much by reason of insufficiency of accommodation as through the lack of any machinery for readjusting the relations of the various authorities concerned —viz., the guardians, the Metropolitan Asylums Board, and the Education and Asylums Committees of the County Council. This division of work involved also a division of authority and a lack of coördination fatal to any successful treatment of the problem, and, holding this view, the Royal Commission specially considered methods of setting up administrative machinery in London.

The report of the Royal Commission was dealt with in THE LANCET at the time of its publication in 1908.[1]

The New Authorities to be Set Up.

On the recommendation of the Commission that there should be "one central authority for the general protection and supervision of mentally defective persons" the Local Government Committee raised the question whether this work could not be undertaken conveniently by the Local Government Board, suggesting that the overlapping of jurisdiction was as great an evil in Government Departments as in the case of local authorities. In regard to the work of the local authority under the Commission's proposal, the Local Government Committee urged the desirability of so constituting the Statutory Committee for the Feeble-minded that when the recommendations of the Poor-law Commission came to be dealt with the nucleus of the organisation for public assistance would be already in existence. Although the powers proposed to be given to the Statutory Committee were not exclusively of the nature of public assistance, in practical administration there would be very considerable similarity, and the two matters were so interwoven that if the two services were placed under separate authorities there would be a danger of overlapping and friction. The difficulty would also occur of finding sufficient members to man two important statutory committees of this kind.

Importance of a Comprehensive Scheme.

The Asylums Committee was of opinion that the recommendation of the Commission with regard to "friendly visitors" to advise as to training, education, or marriage was a serious and common-sense attempt to deal with a very complicated phase of the lunacy question—the inter-marriage and consequent propagation of imbeciles. The committee had been endeavouring for years to secure the establishment of receiving houses and receiving wards, and was therefore much gratified to find the Royal Commission recommending their compulsory establishment. Generally speaking, the Commission gave the proposed committee a very wide discretion, and only experience could show what would be the best course to pursue under certain conditions. The Asylums Committee laid stress on the importance of the question of insanity and feeble-mindedness being comprehensively dealt with. At present the ascertainable body of insanity was obscured by a wide fringe of feeble-mindedness which could not be dealt with adequately under existing powers, and from this fringe lunatics, officially recognised as such, were being recruited constantly. Unless drastic measures were adopted the only prospect of elimination of future generations of the insane and degenerate stock seemed to lie in such measures as suggested by the Royal Commission.

Mentally Defective Children and Inebriates.

On that portion of the recommendation of the Commission dealing with mentally defective school children the Education Committee agreed that a register of mentally defective children should be kept, and thought that the duty of compiling it should fall on the Education Committee, and that some effective means should be devised to prevent duplication or conflict of medical certificates. The committee also agreed that observation centres or homes for scientific and medical differentiation should be established, but was of opinion that the provision of intermediate schools for dull or backward children needed careful consideration, and perhaps an experimental school should be established in the first instance. As to what authority should be responsible for the education and training of mentally defective children considerable difference of opinion existed, but the Education Committee had come to a conclusion in agreement with the Royal Commission that the proposed central authority should be responsible for both children and adults.

The Asylums Committee and the Public Control Committee were in general accord with the recommendations of the Commission with regard to criminal mental defectives and inebriates. The Public Control Committee, however, pointed out that if the recommendation that such inebriates as were mentally defective should be dealt with under the proposals of the Commission a heavy additional financial burden would fall upon local authorities.

The Cost of the Proposals: Respective Shares of the Government and Local Authorities.

The probable effect of the Commission's proposals on local taxation was next considered. The Local Government Committee considered both the methods suggested by the Royal Commission for readjusting local expenditure and exchequer contributions to be open to objection. The block grant system would be unfair to London and other urban areas where the higher rateable values necessitated a higher rate of expenditure. The second method—of adding a new grant for new cases to the grants now paid—would complicate still further the system of imperial subventions. The proposal to make grants for a limited time towards the provision of accommodation would give most assistance to authorities which had been most backward in making proper provision for the mentally defective. It would be more equitable to base the grant on the total accommodation provided.

The Finance Committee pointed out that the extension of control to all mentally defective persons would involve an increase in expenditure, and the financial operations of the proposed statutory committee would be very large. The cost to the Council would come under two heads: (1) Expenditure on services now carried out by other authorities and the Council's own present expenditure; and (2) new expenditure involved by carrying out the proposals of the Commission. There would not be an addition, presumably, to the burdens of the London ratepayer under the first head. Shortly stated, the enlarged scope of operations of the new committee would involve increased expenditure in carrying out the following new duties: (*a*) Detention and control of defective children after school-age; (*b*) compilation of register of mentally defectives; (*c*) appointment of medical officers and certifying medical practitioners; (*d*) detention of mentally defective persons convicted of offences, and control over defective persons who would otherwise frequent the casual wards of workhouses and other shelters; and (*e*) compulsory provision of accommodation for mentally defective inebriates.

The Cost to London.

It was impossible to estimate the cost to London of carrying out the whole of these recommendations, but some idea might be gathered from the figures given by the Commissioners for the whole of England and Wales. They estimated the additional cost at £899,532, or an increase over the present cost of £541,492. The Finance Committee pointed out that savings in administrative expenses owing to coördination and economy, the result of better classification, would occur. Under the present system there was considerable pressure on the relatively costly asylum accommodation by reason of the "feeble and decrepit" old people whom the guardians passed on. The exclusion from lunatic asylums of persons who did not need such expensive treatment should result in considerable economy. It was in order to avoid clogging special institutions with unimprovable cases that the Commission proposed the appointment of one authority in each county or county borough to ensure that persons should be passed on to institutions best fitted for them. It might be assumed that some economy to the public purse would

[1] THE LANCET, Sept. 12th (p. 819), 19th (p. 890), and 26th (p. 959), and Oct. 3rd (p. 1018), 1908.

ensue from the avoidance of the duplication and even triplication of certificates prior to admission which occurred so frequently under the present system. The Finance Committee rejoiced to see in the Royal Commissioners' recommendations unity of financial administration foreshadowed, thus securing to the ratepayers the fullest possible economy. The Finance Committee endorsed the objections of the Local Government Committee with regard to the readjustment of cost between local authorities and the Government, and remarked in conclusion that the care and control of the mentally defective was universally recognised as a national, rather than a local, question; and it was satisfactory to note that the Commission realised and pointed out the need for "substantial financial assistance" from the Exchequer. When the time came it would be imperative for the Council to take steps to ensure that adequate assistance was granted from Imperial funds to meet the cost of carrying out effectively any proposals made as a result of the Commissioners' report.

The Recommendations of the Committees.

The recommendations attached to the joint report of the committees were: (*a*) That the Council welcomes proposals for the coördination of the administration of controlling persons of all ages coming under the term "mentally defective" as defined by the Royal Commission. (*b*) That no opinion be expressed with regard to the constitution of the proposed board of control, but that in the opinion of the Council the control should be vested in a single Government department. (*c*) That if the Council is required to undertake the work it should be discharged through a statutory committee of the Council with the power of coöption, financial control and the determination of new principles to rest with the Council. (*d*) That adequate provision should be made for close coöperation with any authority that may be set up hereafter for dealing with the administration of public assistance. (*e*) That in the opinion of the Council the care and control of mentally defective persons is a national service administered locally, and while not agreeing with the methods proposed by the Royal Commission for the allocation of Imperial grants the Council is of opinion that provision for an appropriate measure of Exchequer assistance should accompany any reorganisation or extension of the administrative machinery for dealing with such persons. (*f*) That a copy of the foregoing resolutions be forwarded to the Government.

In view of the absence of several leading members of the Council in connexion with Parliamentary elections, the consideration of the report was postponed.

Proposals for Increased Accommodation for Defectives.

Reporting concurrently on the provision of accommodation for mentally defective children in London, the Education Committee mentioned that in 1908 the Council decided that no additional schools for the mentally defective should be provided pending the issue of the report of the Royal Commission. In the event of the proposals of the Commission becoming law the special schools for the mentally defective provided by the Council would continue to be carried on, in all probability by the Council, although the expenditure connected with them would not be charged to the education account. Until it was known what action would be taken in regard to the report of the Commission, the committee considered the work of the Council should continue substantially on the present lines—i.e., that accommodation should be provided to meet immediate needs, but that the question of future requirements should remain in abeyance. Following proposals to provide 220 school places for mentally defective children already agreed to, the committee submitted further schemes to provide 610 more places.

The Finance Committee, reporting on these proposals, stated that it had thought of postponing their consideration until the Council's policy in regard to the report of the Royal Commission had been formulated. However, the recommendations of the various committees (see above) were confined to a general approval of the principles of the Commissioners' report, and did not afford much help in the direction of settling the important question of policy to be adopted in meeting the present need for accommodation for mentally defective children in London. It seemed likely that for some considerable time to come day school accommodation would be required for these children, whether or not the education authority continued to be entrusted with their care, and therefore the Finance Committee had given its approval to the Education Committee's proposals. Remembering that special cost twice as much as ordinary school accommodation to provide, the Finance Committee would have advocated, if it were practicable, that some temporary measures should be adopted until the trend of future legislation was ascertained, but the committee was assured that certain difficulties prevented the adoption of this course.

Possibility of Special Schools becoming Obsolete.

In the course of a short discussion on the Education Committee's proposals, Mr. Leon deprecated any further expenditure on provision for defective children until it was seen what action would be taken by the Government on the report of the Royal Commission. While he was by no means opposed to provision for defective children, he objected to the expenditure of large sums of money on their behalf while the normal children suffered through being taught in unduly large classes. He was afraid this expenditure might be an excuse for cutting down the sums allocated to the ordinary elementary schools. Moreover, having regard to the recommendations of the Royal Commission on the subject, he doubted very much if the mentally defective child in the future would be taught in schools of the kind proposed to be erected, and the Council might find it had practically thrown money away. It would be worth while waiting one or two years—he did not think it would be longer—for a national settlement of this question. He regarded it as undesirable to spend large sums in educating these children only to make it more possible for them to increase an undesirable race. Mr. Jay, the chairman of the committee, said he had a great deal of sympathy with what Mr. Leon had said. As there seemed no prospect of the Government dealing with the whole question, the Council was bound to make provision for those children actually out of school, which was all that was proposed to be done. The proposals before the Council had no reference to future requirements. He agreed that their expenditure might turn out in the end to be very unremunerative and unsatisfactory, but, unfortunately, they could not help that. The proposals for additional accommodation were then agreed to.

MEDICINE AND THE LAW.

A Medical Man's Experience of the Workmen's Compensation Act.

A PAPER recently read by Dr. R. J. Collie at the eleventh Congrès International des Maladies Professionnelles, held at Brussels,[1] contains much that is instructive and suggestive with regard to the administration and practical working of the Workmen's Compensation Act, 1906. This more or less recent statute has now been on trial long enough for its weak points to have been fairly well brought home to employer and employed. It has caused and is causing considerable expenditure to the former, who does not grudge this when it provides compensation in cases of undeserved and unavoidable incapacity occurring by accidents to his servants, but who at the same time finds himself laid open to exploitation in many instances in a manner inconsistent with the acknowledged principles of law and justice. Dr. Collie informs us that in the 12 months preceding the reading of the paper referred to, he conducted 1464 examinations of injuries, of which 844 were examinations of medico-legal cases, mostly in connexion with threatened actions at common law, but many of them under the Workmen's Compensation Act. He speaks, therefore, as an expert looker-on or as one of those who proverbially see most of the game, and from his point of vantage he has made the most of his opportunities for observation. Fully alive to the benefits conferred by the Act upon the genuine case of accidental injury, he has also been strongly impressed by the physical and moral injury arising to the workman, who is induced to become an idler, a pseudo-neurasthenic,

[1] The Medico-legal Aspect of the British Workmen's Compensation Act, 1906, a paper read at Brussels, Sept. 10th-14th, 1910, by R. J. Collie, M.D., J.P., Medical Examiner for the London County Council, Chief Medical Officer for the London Water Board, Examiner (Accidents and Claims), Sun Insurance and other Accident Offices. London: Baillière, Tindall, and Cox, 1911, pp. 40.

and a malingerer by the temptation to formulate a fraudulent or inflated claim for compensation. We need not dwell upon the methods of the malingerer, with the exposure of which Dr. Collie's name is sufficiently associated for objection to have been made recently in London to his examining a workman, alleged to have been injured, except in the presence of his solicitor—an objection not upheld by the court. Dr. Collie points out that the evils arising out of claims of the kind suggested might be minimised by easy and uncomplicated alterations of procedure for which he makes practical suggestion. In particular he points to the rare and ineffective use made of the medical referees which the present Act and its predecessor have called into being. In cases under the Act of 1906, when a claim is made in respect of industrial diseases ranking as accidents, a certifying surgeon appointed under the Factory and Workshop Act, 1901, has to give a certificate of incapacity, or to refuse it. If the employer or the workman is aggrieved by the act of the certifying surgeon in this respect the matter is to be referred to a medical referee, whose decision is final. Thus the last word upon a disputed point of a purely medical nature is spoken by a specially qualified medical man. In other cases the most keenly fought contests upon questions equally of a scientific character may take place with highly technical expert evidence on both sides before a county court judge alone; an impartial judge no doubt, but a layman wholly unqualified to decide "when doctors disagree." It is true that a case may be referred to a medical referee on the application of both parties; but Dr. Collie points out that, as might be expected, this very rarely takes place, and he suggests that either party, instead of both by agreement, should be able to claim to have the medical decision of the case placed in the hands of a medical referee. Again, the medical referee may be summoned by the judge to sit with him as an assessor. The inefficacy of this provision in practice is shown by the fact that in one year (1908) medical referees were summoned to sit with judges in 145 cases only, so that as there were about 340 medical referees in existence not one-half of their number acted as assessors in the course of a whole year. The suggestion made by Dr. Collie on this point is that a medical referee should sit as assessor on the application of either party. Thirdly, the judge may submit to a medical referee for report any matter which seems material. In this case it appears to be open to the judge or arbitrator to act upon the referee's report and to treat it as conclusive, but he is not bound to do so, and here again the intervention of the referee is in the discretion of the judge, and is not to be brought about by one of the parties who may desire to have a medical question submitted to an independent medical expert. Dr. Collie would have medical referees appointed in large centres as whole-time, salaried officials, like county court judges, occupying as these do entirely independent positions, and he is of the opinion that no better course could be followed than that recommended by the Departmental Committee on the Workmen's Compensation Act, 1906—namely, that in six selected districts independent State-paid medical referees should be instituted as an experiment, and that the plan should be gradually extended if it were to be found to work satisfactorily. A practical suggestion made on behalf of the working man should be noted by those inclined to think that, occupied with the unmasking of the malingerer, Dr. Collie is unable to appreciate the point of view of those for whose benefit the Act was passed. He points out that the provision against "contracting out" in any form inflicts considerable hardship upon those workmen who suffer from some physical incapacity which suggests a possible predisposition to accidental injury, or which might increase the consequences of injury if an accident of a particular kind were to happen. As the law stands, a workman who so suffers is almost sure to be refused employment in many instances where he would obtain it if he were to be permitted to "contract out" of his right to compensation for injuries due to, or increased by, the conditions specified in his contract. Possibly when the legislature has leisure to consider matters of the class referred to above, in the light of experience such as that of Dr. Collie, the Workmen's Compensation Act, 1906, may be amended so that it will work more justly to both classes—employers and employed, and in such a manner as to minimise its corrupting influence upon the latter. At present, to take the figures of the year 1908, out of 323,957 claims in respect of industrial accidents only 2503 were decided in the courts, and out of 2503 claims which came into court 82 per cent. ended in favour of the applicants for compensation. Where the odds are so long against the defending party and where the litigation is at the suit of an adversary who cannot in the event of losing pay the costs of the successful litigant, caution deters the insurance company from the contest, and claims are settled, not because they are just, but because it is cheaper to give way than to seek justice.

An Action for Libel.

At the Leeds assizes recently, before Mr. Justice Lawrence and a jury, an action was brought by Mrs. Louisa Robinson of Halifax against Dr. J. P. I. Harty and Mr. A. N. Brushfield of Halifax to recover damages for an alleged libel contained in a medical certificate to the guardians in which it was suggested that she was a malingerer. The plaintiff conducted her own case, while the defence was in the hands of Mr. J. A. Compston, instructed by Messrs. Hirst and Whitley on behalf of the London and Counties Medical Protection Society. Mr. Compston submitted that there was no case for the defendants to answer. It was a matter of privilege and was also hopelessly out of time. His lordship agreed, and the jury returned a verdict for the defendants.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 7242 births and 5866 deaths were registered during the week ending Dec. 3rd. The annual rate of mortality in these towns, which had steadily increased in the five preceding weeks from 13·0 to 17·3 per 1000, further rose to 18·1 in the week under notice. During the first nine weeks of the current quarter the death-rate in these towns averaged 14·5 per 1000. In London during the same period the death-rate, calculated on the probably over-estimated population, was equal to 15·2 per 1000. The annual rates last week in the 77 towns ranged from 7·2 in Handsworth, 8·5 in Walthamstow, 11·0 in Willesden, and 11·3 in East Ham, to 22·4 in Dewsbury, 22·7 in Swansea, 24·8 in Huddersfield, and 26·2 in Great Yarmouth. The 5866 deaths from all causes in the 77 towns last week showed a further increase of 249 on the numbers returned in recent weeks, and included 416 which were referred to the principal epidemic diseases, against numbers increasing from 361 to 420 in the four preceding weeks; of these 416 deaths, 231 resulted from measles, 49 from diarrhœa, 45 from whooping-cough, 42 from diphtheria, 25 from scarlet fever, and 24 from enteric fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·3 per 1000, and corresponded with the rate in the previous week. No death from any of these epidemic diseases was registered last week in Rhondda, Leyton, Southampton, South Shields, Halifax, or in 10 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·9 in Rotherham, 4·2 in Grimsby, 4·3 in Brighton, and 6·5 in Tynemouth. The fatal cases of measles in the 77 towns, which had steadily increased in the four preceding weeks from 101 to 192, further rose last week to 231, and exceeded the number in any previous week of this year; they caused the highest annual rates, 2·4 in Portsmouth, 2·8 in Grimsby, 3·1 in Rotherham, 3·6 in Brighton, and 3·7 in Tynemouth. The 49 deaths attributed to diarrhœa in the 77 towns showed a further decline from recent weekly numbers. The 45 deaths from whooping-cough were fewer by 11 than those returned in the previous week, but caused an annual rate equal to 1·5 per 1000 both in Wolverhampton and in Middlesbrough. The 42 fatal cases of diphtheria also showed a distinct decline from recent weekly numbers, but included 14 in London and its suburban districts, 3 in Birmingham and King's Norton, 3 in Manchester, and 2 each in Bolton, Bury, and Sunderland. The 25 deaths from scarlet fever were within one of those returned in the previous week; 5 occurred in Liverpool and 2 both in Manchester and Leeds. The deaths referred to enteric fever, which had been 32, 21, and 25 in the three preceding weeks, were 24 last week, of which 7 were returned in London and its suburban districts, 3 in Wigan, and 2 both in Manchester and Grimsby.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had been 1882, 1843, and 1769 at the end of the three preceding weeks, had further declined to 1746 on Saturday last; 170 new cases of this disease were admitted to these hospitals during last week, against 180 and 153 in the two previous weeks. The 1974 deaths from all causes in London last week included 669 which were referred to pneumonia and other diseases of the respiratory system, against numbers increasing from 246 to 558 in the four preceding weeks; they exceeded by 274 the corrected average number in the corresponding week of the five years 1905–09. The causes of 52, or 0·9 per cent., of the deaths registered during last week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified last week in London and in its eight suburban districts, in Manchester, Bristol, Bradford, Newcastle-on-Tyne, Nottingham, and in 42 other smaller towns; the 52 uncertified causes of death in the 77 towns last week included 9 in Liverpool, 6 in Birmingham, 4 in Stoke-on-Trent, 4 in Rochdale, and 3 each in Portsmouth, Leicester, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 780 births and 633 deaths were registered during the week ending Dec. 3rd. The annual rate of mortality in these towns, which had been equal to 13·3, 16·2, and 16·5 per 1000 in the three preceding weeks, further rose to 17·5 in the week under notice. During the first nine weeks of the current quarter the death-rate in these eight towns averaged 14·5 per 1000, and corresponded with the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 11·2 and 16·9 in Aberdeen and Edinburgh, to 21·0 in Perth and 22·2 in Leith. The 633 deaths from all causes in the eight towns last week showed a further increase of 33 upon the numbers in the three preceding weeks, and included 47 which were referred to the principal epidemic diseases, against 61 and 55 in the two previous weeks; of these 47 deaths, 16 resulted from diarrhœa, 11 from diphtheria, 10 from whooping-cough, 5 from scarlet fever, 3 from "fever," and 2 from measles, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·3 per 1000, and corresponded with the rate from the same diseases in the 77 English towns. The deaths attributed to diarrhœa in the Scotch towns, which had been 17, 24, and 15 in the three preceding weeks, were 16 last week, and included 5 in Glasgow, 4 in Dundee, and 3 in Edinburgh. The 11 fatal cases of diphtheria showed a decline of 3 from the number in the previous week; 5 occurred in Glasgow, and 2 both in Dundee and Perth. The deaths from whooping-cough, which had been 13 and 12 in the two previous weeks, further declined last week to 10, of which 7 were returned in Glasgow and 3 in Leith. The 5 fatal cases of scarlet fever were fewer by 6 than the number in the previous week, and included 2 in Glasgow. The 3 deaths referred to "fever" included 2 certified as enteric fever, and 1 as cerebro-spinal meningitis. The deaths referred to diseases of the respiratory system in the eight towns, which had been 65, 121, and 138 in the three preceding weeks, further rose to 157 last week, but were 108 below the number in the corresponding week of last year. The causes of 15, or 2·4 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 554 births and 400 deaths were registered during the week ending Dec. 3rd. The mean annual rate of mortality in these towns, which had steadily increased in the four preceding weeks from 15·1, to 19·1 per 1000, declined again to 18·1 in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these Irish towns averaged 17·0 per 1000; the mean rate during the same period did not exceed 14 5 in the 77 largest English towns or in the eight Scotch towns. The annual death-rate during last week was equal to 21·9 in Dublin, 14·5 in Belfast, 13·7 in Cork, 15·6 in Londonderry, 23·2 in Limerick, and 19·5 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 19·2 per 1000. The 400 deaths from all causes in the 22 town districts last week showed a decline of 23 from the number in the previous week, and and included 36 which were referred to the principal epidemic diseases, against 18 and 29 in the two previous weeks; these 36 deaths were equal to an annual rate of 1·6 per 1000; in the 77 English towns and in the eight Scotch towns the mean rate from the same diseases last week did not exceed 1·3 per 1000. The 36 deaths from these epidemic diseases in the Irish towns last week included 14 from measles, 9 from diarrhœa, 5 from diphtheria, 5 from whooping-cough, 3 from scarlet fever, and not one either from enteric fever or small-pox. The 14 fatal cases of measles showed a further increase of 6 upon the numbers in recent weeks, and included 8 in Lurgan, 4 in Armagh, and 2 in Belfast. The 9 deaths attributed to diarrhœa also showed an increase, 6 being returned in Dublin. All the 5 fatal cases of whooping-cough, 3 of the 5 deaths from diphtheria, and the 3 deaths from scarlet fever also occurred in Dublin. The deaths in the 22 towns last week included 108 which were referred to pneumonia and other diseases of the respiratory system, against 80 and 100 in the two preceding weeks. The causes of 22, or 5·5 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·9 per cent., and in the eight Scotch towns it was equal to 2·4 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: W. G. K. Barnes to the *President;* E. B. Pickthorn to the *Prince of Wales*, on recommissioning; G. H. Foott to the *Albemarle*, on recommissioning; and A. H. H. Vizard to the *Queen*, on recommissioning. Staff-Surgeons: K. H. Jones to the *Highflyer*, on commissioning; H. P. Turnbull to the *Hannibal*, on recommissioning; R. W. Stanistreet to the *Euryalus*. Surgeons: H. B. German to be lent to the *Euryalus*, temporarily; A. G. V. French to the *Prince of Wales*, on recommissioning; S. Bradbury to the *Queen*, on recommissioning; L. C. E. Murphy to the *Vivid*, additional, for disposal on the *Commonwealth* reducing; and J. H. McDowall to the *Pembroke*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

The undermentioned officers from the Seconded List, are restored to the establishment (dated Nov. 18th, 1910):—Captain William M. B. Sparkes, and Lieutenant Harold T. Treves.

The following officers have been detailed to take part in a medical staff ride in the vicinity of Salisbury: Surgeon-General H. R. Whitehead, C.B., principal medical officer of the Southern Command; Lieutenant-Colonel W. T. Swan, Major E. A. Burnside, Major N. Tyacke, Major A. E. Milner, Major C. B. Lawson, Major W. E. Hudleston, Major W. A. Ward, and Major P. H. Collingwood. Surgeon-General J. G. MacNeece, principal medical officer of the Eighth (Lucknow) Division, has joined at Lucknow, from Naini Tal. Colonel M. W. Kerin, officiating principal medical officer of the Seventh (Meerut) Division, has taken up duty at Mussooree. Lieutenant-Colonel E. J. R. Risk, administrative medical officer, Belfast District, has been selected to succeed Colonel D. Wardrop, C.V.O., as Commandant and Director of Studies at the Royal Army Medical College, whose tenure of the appointment will expire on Feb. 4th next. Lieutenant-Colonel G. Cree, from Madras, has been appointed to the Eastern Command for duty. Lieutenant-Colonel H. M. Thompson, D.S.O., commanding the Station Hospital at Lucknow, has arrived home on leave. Lieutenant-Colonel F. W. Caton Jones, from Tidworth Park, has been selected to command the Station Hospital at Quetta. Lieutenant-Colonel W. L. Reade, from Dublin, has joined at Mauritius. Lieutenant-Colonel C. T. Blackwell has been appointed to command the

Station Hospital at Madras. Lieutenant-Colonel T. B. Winter has arrived home, tour-expired from India. Major J. W. Jennings, D.S.O., has been transferred from Chester to Liverpool and posted as Recruiting Medical Officer. Major A. E. Thorp, from Tidworth Park, has embarked for a tour of foreign service in South Africa. Major G. B. Riddick, from Maymyo, has taken up duty at Rangoon. Major G. H. Goddard, from Alderney, has been appointed to the Medical Charge of the Military Families Hospital at Shorncliffe. Major H. G. Stallard, Captain J. G. Foster, and Captain H. E. Howley have embarked in H.M.T. *Dongola* for a tour of service in India. Captain M. Keane has been appointed Staff Surgeon in charge of Meerut Divisional Headquarters, vice the late Major R. Selby. Captain H. C. R. Hime, in charge of the Brigade Laboratory at Madras, has been appointed a Specialist in the Prevention of Disease. The following officers (Captains) have joined at the Royal Army Medical College for a course of instruction for promotion to the rank of major:—F. J. Brackenridge, R. B. Black, P. Davidson, D.S.O., R. L. V. Foster, S. M. W. Meadows, D. S. Skelton, J. G. Bell, A. E. B. Wood, J. C. G. Carmichael, R. H. Bridges, J. A. W. Webster, F. C. Lambert, J. B. Meldon, R. C. Wilmot, H. B. Kelly, E. M. Pennefather, B. H. V. Dunbar, D. G. Carmichael, J. M. M. Crawford, and C. Bramhall. Captain C. H. Turner has arrived home from India, tour-expired. Captain E. W. Powell, from Belgaum, has joined at Aden and has been appointed to the charge of the Brigade Laboratory. Captain W. R. P. Goodwin, from Woolwich, has been placed under orders for a tour of service in India. Captain R. B. Black, on the termination of his appointment with the Egyptian army, has had the order of the Osmanieh (Fourth Class) conferred on him by the Khedive. Captain W. McConaghy has been transferred from Wedgnock Camp to Tidworth Park. Captain J. du P. Langrishe, from Mhow, has joined at Poona. Lieutenant H. T. Treves, on return from special service under the Colonial Office in Uganda, has been posted to the London District. Lieutenant M. J. Williamson has joined at Tidworth Park from Hamilton Camp. Lieutenant A. G. Moutray has been granted nine months' leave home from India.

INDIAN MEDICAL SERVICE.

Surgeon-General C. P. Lukis, C.S.I., Director-General of the Indian Medical Service, has been appointed an Ordinary Fellow of the Calcutta University. On relief by Colonel C. F. Willis, Lieutenant-Colonel J. W. Rodgers has been appointed to officiate as Principal Medical Officer of the Sirhind and Jullundur Brigades during the absence on eight months' leave of Colonel A. M. Crofts, C.I.E. Lieutenant-Colonel W. H. Quirke, Bombay, has been granted three months' extension of his leave on medical certificate. Lieutenant-Colonel R. J. Marks, on return from leave, has been appointed Civil Surgeon at Gorakhpur. Lieutenant-Colonel H. F. Cleveland, secretary to the Principal Medical Officer His Majesty's Forces in India, has arrived home on leave. Major J. W. Grant has been appointed by the Foreign Department of the Government of India to be Residency Surgeon to the Western States of Rajputana, in succession to Lieutenant-Colonel R. C. Macwatt, who has proceeded on combined leave. Major W. H. Kenrick, civil surgeon at Nimar, has been placed on special duty under the orders of the Sanitary Commissioner of the Central Provinces. On return from furlough Major D. W. Sutherland has taken up duty as Principal and Professor of Medicine and Diseases of Children at the Medical College, Lahore, relieving Major H. G. Melville. Major W. Selby has been transferred from Gorakhpur to Lucknow as Civil Surgeon. Major C. Thomson has received an extension of his leave to Jan. 29th next. The services of Captain A. C. MacGilchrist, officiating Professor of Materia Medica at the Medical College, Lahore, have been replaced at the disposal of the Government of India. Captain S. B. Mehta has been appointed Assistant District Plague Medical Officer at Lyallpur. Captain H. Watts, Bombay, and Captain F. N. White have arrived home on leave from India. On return from duty at Pachmarhi Captain J. M. C. MacMillan has been appointed Civil Surgeon at Hoshangabad, Central Provinces. Captain S. C. Chuckerbutty has been posted for plague duty at Bassein. Captain H. Ross has joined the Civil Medical Department of the United Provinces and has been appointed Civil Surgeon of Etawah. Captain A. H. Proctor has received an extension of his leave to Feb. 16th next. Captain J. F. Boyd, in charge of the Brigade Laboratory at Bannu, has been appointed a Specialist in the Prevention of Disease. Captain M. F. White has embarked for Bombay on the expiration of his leave home.

The King has approved of the retirement of the undermentioned officers of the Indian Medical Service: Colonel Patrick Alexander Weir (dated Oct. 26th, 1910), and Lieutenant-Colonel Robert Evans Stuart Davis (dated Oct. 29th, 1910).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

2nd Highland Field Ambulance, Royal Army Medical Corps: Lieutenant Lewis D. Cruickshank to be Captain (dated Nov. 7th, 1910).

CHANNEL ISLANDS MILITIA.

The Royal Militia of the Island of Jersey.

Medical Corps: Surgeon-Lieutenant Henry J. Shone to be Surgeon-Captain (dated Nov. 25th, 1910).

ROYAL ARMY MEDICAL CORPS JOURNAL.

In the December issue of this journal, which closes the fifteenth half-yearly volume, Major J. C. B. Statham, R.A.M.C., describes an outbreak of fever due to bacteria having unusual cultural characters "in that, though possessing many of the features of the typhoid colon group of bacteria, they ferment saccharose markedly and do not affect dulcite." Captain A. R. Tweedie, R.A.M.C. (T.), discusses the question of ambulance wagons, believing that "the fact that at least three patterns of ambulance wagons are now being used in the service affords sufficient reason to assume that no ideal type has yet been attained." His contention is that all further efforts in ambulance wagon construction should be developed on the lines of "Mark I. (Light)." Major E. C. Freeman, R.A.M.C. (R.P.), deals with the question of clearing hospitals and the Territorial Force. With regard to the Red Cross organisation, he is of opinion that it should be carried out by the medical service of the Territorial Force, and for this purpose all the Voluntary Aid Detachments should be put under the inspection of the administrative medical officer of the Territorial Force division in which they are situated, or of someone delegated by him for the purpose. This issue of the journal also contains a further instalment of the Medical History of the South African War, by Lieutenant-Colonel R. J. S. Simpson, C.M.G., R.A.M.C.

OSBORNE: REPORT OF THE HOUSE GOVERNOR AND MEDICAL SUPERINTENDENT.

The report of the house governor and medical superintendent of Osborne, Surgeon-Lieutenant-Colonel C. R. Kilkelly, for the year ended March 31st, 1910, has just been presented to Parliament. It states that there has been no variation in the accommodation provided—viz., for 43 officers and five ladies. The admissions during the year comprised 200 officers and 69 ladies—total 269, as compared with an average of 289 in the three preceding years. The average daily number in residence was 32·50. The average duration of each case of illness was approximately six weeks. The decrease in admissions is accounted for by (1) insufficient knowledge of the benefits of Osborne amongst sick officers; (2) the very large reduction in the invaliding home of officers similar to the reduction effected in the invaliding of soldiers which has taken place during the last two or three years; and (3) the establishment of nursing homes and institutions for sick officers in the hills in India where many cases pass their period of convalescence instead of coming home under the new regulations. As in previous years, by far the largest number of officers admitted belong to the home army, and nearly 33·5 per cent. of the total number of admissions were for diseases contracted on service in India. The admissions from the Royal Navy compared with those from the army furnish a ratio which agrees with the relative strengths of the navy and army in officers—viz., 1 to 7. The largest number of admissions were for (*a*) infective diseases (51), principally dysentery; (*b*) diseases of the nervous system (22), chiefly neurasthenia; and (*c*) diseases of the digestive system (65), principally inflammation and ulceration of the stomach and intestines and liver abscesses. Enteric fever, influenza, malaria, and Malta fever accounted for 24 admissions. The

two cases of Malta fever were contracted in Somaliland. All the cases of dysentery have done specially well under treatment at Osborne. The five admissions for tuberculosis were limited in extent and did not implicate the lungs. A case of malignant new growth was transferred for further treatment to the Queen Alexandra Hospital, Millbank, where the patient died. The cases of neurasthenia nearly all required more or less complete courses of Weir Mitchell treatment. The general results in these cases have been excellent considering their nature and the usually prolonged duration of the previous illness prior to treatment. There were nine admissions for various diseases of the heart and four underwent a course of treatment by Nauheim baths and Schott's exercises. The diseases of the digestive system formed the largest group of cases, and many of them had undergone operations. They included cases of appendicitis, colitis, gastro-duodenal ulcers, sprue, and liver abscesses. A case of multiple stricture of the colon was suspected to be the result of glass poisoning in India. The cases of liver abscess were the result of dysentery contracted in India. One case of liver abscess was passed fit for service by the Medical Board last February after an illness lasting since September, 1907. Amongst the general injuries a case of shock was the result of a fall of 50 feet from a kite whilst experimenting at Aldershot. There were 74 post-operation cases. There was no death. His Majesty the late King and his Majesty King George, and other members of the Royal Family visited Osborne on several occasions, and expressed their approbation of the work done. Members of the consulting staff and house committee have visited Osborne about twice every month for the purpose of consultation and inspecting the medical, nursing, domestic, and general arrangements. Sick officers in residence have constantly availed themselves of the advice tendered them as regards their health by the consultants, who have in addition frequently given them further advice and treatment gratuitously in their consulting rooms in London. The officers of the Queen Alexandra Military Hospital and the Royal Army Medical College have given much help in the treatment of cases and investigation of disease.

Correspondence.

"Audi alteram partem."

THE GENERAL MEDICAL COUNCIL AND THE PROPOSED ANÆSTHETICS ACT.

To the Editor of THE LANCET.

SIR,—As will be seen from the account of the recent proceedings of the General Medical Council[1] another definite step has been taken towards securing legislation in regard to anæsthetics. The Council has adopted the report of its Anæsthetics Committee concerning the memorandum and draft Bill submitted by the Home Secretary to the Privy Council and referred by that body to the General Medical Council for its observations thereon, and as that report is favourable to the Bill and urges the necessity for speedy legislation, it may be hoped that during the next session this or some similar Bill will be laid before Parliament. Whilst no one realises more than I do the public-spirited interest which the General Medical Council and its Anæsthetics Committee have taken, and are still taking, in this much-needed reform, I feel that, as I was responsible for the drafting of the Bill, I should like to be allowed to draw attention, though your columns, to the second of the six observations which that Council has just forwarded to the Privy Council concerning the Bill in question. The effect of the suggested amendment to Clause I. would be to permit and perhaps to encourage registered dentists to administer, for operations other than dental, the general anæsthetic or anæsthetics which the General Medical Council might from time to time include in a schedule to the Act; and the question naturally arises whether such an arrangement would give to the public that degree of protection to which, by common consent, it is entitled. Personally I venture to suggest that it would not do so, and as this was the view which the General Medical Council originally held when this proposed addition to the ordinary functions of dentists was first mooted, I hope it may not be too late again to refer to the subject. Both Dr. Blumfeld and I have already advanced in your columns[2] reasons against registered dentists administering anæsthetics in general surgical practice; and with the hope that the General Medical Council, when the present draft Bill comes back for final consideration, may see its way to reconsider this point, I venture to summarise the chief objections which seem to me to stand in the way of the proposed amendment.

The suggestion that dentists should be permitted to administer certain anæsthetics in general surgical operations was, I believe, made on the assumption that such a scheme would be of great convenience in country districts and small provincial towns where medical men might not be available at the moment when an anæsthetic was required, whilst the proposal seemed to acquire additional force from the further assumption that medical men were, as a class, inferior to dentists, so far as the administration of nitrous oxide was concerned. But as there are no registered dentists in country districts, and as practically every provincial town possessing but one dentist possesses also at least five medical men, amongst whom there would surely be one or more with an equal, if not a greater, knowledge of nitrous oxide than that possessed by the local single-handed dentist, it is, I confess, difficult to see the necessity for such a proposal. Even if it be admitted that there are many dentists who are more familiar with the administration and effects of nitrous oxide than many medical men, I would venture to say, with due respect to all those who may hold opposite views, that if by legislative enactment or otherwise it were to become the recognised custom for medical men to call in dentists to administer nitrous oxide or other anæsthetics in general surgery we should be placing all present and future medical students in the absurd position of being obliged to obtain instruction in the use of anæsthetics which, under certain conditions contained in a paradoxical Act of Parliament, they would not be expected to administer. Surely the General Medical Council, by insisting upon such an amendment to the Bill, would be putting back the clock; surely they would be commencing to undo the good work they have already done in insisting upon the proper instruction of all medical students in all general anæsthetics. But there are even weightier considerations than these—considerations regarding the patients submitted to the anæsthesia in question. From the point of view of the public, can we honestly say that a patient who, let us suppose, is ill, and is the subject of some grave visceral disease, should be anæsthetised, even for an apparently trifling operation, by a man who has had, at all events whilst in practice, no clinical experience of disease? I feel sure the dental profession will not misunderstand me in this argument. No one realises more than I do the excellence of the educational curriculum through which dental students pass and the high character of the work which that profession is doing for the public. But I do not think, and I believe that many, if not most, dentists will agree with me, that this excursion from dental into medical practice is called for, nor do I think that it would be to the interests of dentists themselves. Moreover, there are many apparently simple surgical operations which, when begun, develop into more extensive procedures, demanding at the moment a more prolonged or deeper anæsthesia; in other words, an anæsthesia which the dentist, as the anæsthetist in attendance, would neither be prepared nor legally entitled to produce. After a somewhat extensive experience with anæsthetics, and particularly with nitrous oxide, I feel more or less compelled to record my conviction that an amendment of the Bill such as that proposed would be distinctly detrimental to the public interest, for it would reopen the door to certain risks of general anæsthesia which might otherwise be prevented. As the regulations of the General Medical Council with regard to the instruction of all medical students in anæsthetics have now been in force for some time, it is obvious that the country is gradually being furnished with medical men who are able not only to administer ether and chloroform for major operations but nitrous oxide in so-called minor surgery.

I trust, Sir, that those of your correspondents who may be interested in the question of legislation in regard to

[1] THE LANCET, Dec. 3rd, 1910, p. 1625.

[2] THE LANCET, March 26th (p. 888) and April 9th, 1910 (p. 1027).

anæsthetics will express their views on the point to which I have referred. Like the main issue—that of protecting the public against the use of anæsthetics by unqualified persons—the point I have raised is one which, after all is said and done, should be decided by what is best in the interests of the patient. I am, Sir, yours faithfully,

Dec. 6th, 1910. FREDERIC HEWITT.

THROMBOTIC SOFTENING OF THE SPINAL CORD AS A CAUSE OF SO-CALLED "ACUTE MYELITIS."

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 3rd Dr. F. E. Batten says, "Most observers will be in entire agreement" with most of the views expressed in my article in THE LANCET of Nov. 26th, and in partial confirmation he refers me to the recent article on Acute Myelitis in Clifford Allbutt's "System of Medicine," Vol. VII., p. 645, 1910.

I ought to say that my article was written just 12 months ago, and therefore some time before Vol. VII. of the admirable re-issue of the "System of Medicine" had appeared. On referring to this volume I find that while the question at issue is carefully considered the old term of acute myelitis is retained on the ground of clinical convenience (?) and long usage, as well as because "the result of an acute or sub-acute focal lesion of the spinal cord is a clinical picture which varies with the site more than with the nature of the morbid process. An accurate diagnosis of the latter is often possible only after death, and not always then if the disease is of long standing."

But these difficulties are precisely as applicable to the cerebral as to the spinal affections, so that I can only regret that in the new "System" the opportunity has not been taken to rectify the inconsistency of attributing to inflammation in the spinal cord what in the parallel affections of the brain are universally acknowledged to be results of degeneration from vascular occlusions.

Correct treatment in the early stages of the spinal affection must be dependent upon a correct diagnosis, and if the practitioner is taught to regard the common run of cases of so-called "acute myelitis" as of an inflammatory nature, is he not really being led astray?

In regard to the nature of acute poliomyelitis, this has long been a source of doubt and difficulty. The little that I had to say on this subject was mainly directed to the improbability of its being due to a strictly limited common inflammation. I am quite prepared to admit, however, that much recent evidence goes to show that it is really an infective disease of a very obscure nature.

I am, Sir, yours faithfully,

London, Dec. 3rd, 1910. H. CHARLTON BASTIAN.

To the Editor of THE LANCET.

SIR,—Dr. Bastian is so intimately associated with the evolutionary history of neurology, and his share in elucidating many of its most difficult problems during the last half of the nineteenth century is so great, that any paper from his pen is eagerly read by those who are proud to call themselves his pupils. In THE LANCET of Nov. 26th there appears an article by Dr. Bastian with the above title, an article which many, I think, will agree with me should not be allowed to pass without comment or even without respectful criticism.

The earlier part of Dr. Bastian's paper expresses his view that the thrombotic element in acute myelitis, to which he has done so much to draw attention, has not received appropriate recognition. The following two quotations illustrate Dr. Bastian's feeling on this point:—

> Yet works on medicine at the present day and for some time past would have us believe that while the common softenings of the brain are results of non-inflammatory degenerations, those of the spinal cord are due to inflammation. What explanation can be given for this seemingly unwarrantable discrepancy?

> My views on this subject have met with only a very partial acceptance in this country, as may be gathered from the fact that in the last edition but one of the Nomenclature of Diseases, issued by the Royal College of Physicians of London, and probably also in the latest edition, as well as in Sir Clifford Allbutt's celebrated new "System of Medicine" (Vol. VII., 1899) there is no mention of softening of the spinal cord other than such as is assumed to be due to inflammation.

It would be sad, indeed, if these quotations really indicated the state of our attitude towards the question at the present time, and I hasten to assure Dr. Bastian that his suspicions are unfounded. If Dr. Bastian had read the article on Myelitis in the current edition of Sir Clifford Allbutt's "System," instead of that which was published 11 years ago, or the article on Myelitis in Osler's "Modern Medicine," or the article in Turner and Stewart's "Text-book of Nervous Diseases," he would have come to an entirely different conclusion and we should not have felt hurt by the suggestion that his writings of 20 or 30 years ago have failed to find the loyal support which they so richly deserve at the present time.

If, on the other hand, Dr. Bastian would have us discontinue employing the term "myelitis" for describing those cases of spinal disease in which thrombosis plays an important part, he raises a difficult question which he will find discussed at some length in both the Systems of Medicine alluded to above. It is too lengthy a subject to enter upon here, but reference may, perhaps, be permitted to two facts: (1) Myelitis does not strictly mean inflammation of the spinal marrow; and (2) syphilitic arteritis, which is the cause of the immense majority of cases of spinal thrombosis, is, after all, an inflammatory process.

The latter part of Dr. Bastian's article is an attempt to put back the clock and to reinstate old fallacious and confusing theories about acute poliomyelitis, and I cannot help expressing regret that it should have appeared. Acute poliomyelitis is as different from acute myelitis, with thrombotic softening, as is small-pox from superficial gangrene, or as is typhoid fever from a gastric ulcer. I can hardly believe that Dr. Bastian would still support the "primary thrombotic theory" of acute poliomyelitis if he were acquainted with the work of the last five years on the pathology and pathogenesis of that disease. The non-specific thrombotic theory was built up on the appearances observed in cases of poliomyelitis examined at lengthy periods after the onset of the disease, and the whole structure of that theory has tumbled to pieces with the careful examination of recent cases; even the débris has been cleared away by the experimental investigations of Simon Flexner and other workers in the same field. No one will deny that thrombosis occurs in the inflammation of poliomyelitis, just as it occurs in inflammation of any tissue, but recent work on the Continent, in America, and England has proved beyond doubt that the lesion of poliomyelitis, both in its endemic and epidemic form, is a widespread inflammation involving, besides the anterior horns, other parts of the cord, as well as the meninges in many cases, and that thrombosis may occur here and there only as a secondary phenomenon. It is most important for the medical profession to realise these facts, to regard the disease as a specific one due to an infective agent which has already been inoculated into monkeys with the reproduction of the identical disease in those animals, and to do all that is possible, by careful observation of the conditions under which it occurs, to advance our scientific knowledge of the disease.

Writing three years ago I expressed my belief that before long acute poliomyelitis would be included in the category of the acute specific fevers. It has the constitutional disturbances, the age incidence, the seasonal exacerbations, the sporadic and epidemic types, the immunity from second attacks, associated with the obscurity as to its bacterial origin, which are shown by measles, scarlet fever, and varicella, and the severe inflammatory lesions, limited to particular tissues, which are met with in scarlet fever, diphtheria, and variola. This belief has only been strengthened during the last three years, and I venture to prophesy that before very long acute poliomyelitis will be included among the notifiable diseases in this country, as it has been already elsewhere. My prophecy will certainly not be fulfilled if Dr. Bastian is right in believing "that there is very much evidence against the view that inflammation is at all a common cause of so-called acute poliomyelitis," and "that vascular occlusions or acute primary degenerations of the very specialised ganglion cells will suffice to account for the great majority of cases."

I am, Sir, yours faithfully,

Wimpole-street, W. E. FARQUHAR BUZZARD.

THE MOTOR FUNCTIONS OF THE STOMACH.

To the Editor of THE LANCET.

SIR,—In one of Mr. H. M. W. Gray's papers on the "Motor Functions of the Stomach," published in THE LANCET of 1908, he ascribes the discovery of secretin to Wertheimer, without even mentioning the names of Bayliss and Starling. As this is only one example of numerous inaccuracies in the papers, it is surprising that they evoked no public criticism at the time. As, however, there is a danger of frequently repeated errors being finally accepted as facts, it is desirable that some of the mistakes in Mr. Gray's recent article in THE LANCET of Dec. 3rd should be corrected.

My first observations on the human stomach with the X rays were made in the horizontal position, and I was led—like Mr. Gray—to believe that the stomach is divided into two parts, anatomically and functionally distinct. When I began to examine the stomach in the vertical position also, I soon found that I had been mistaken, and I am now convinced that there is no such thing as a "middle sphincter." It would occupy too much space to give my reasons in detail, but I may refer Mr. Gray to my paper on the subject in the *Quarterly Journal of Medicine* for July, 1910.

It is easy to see with the X rays that peristalsis begins near the centre of the stomach, where it produces a shallow depression, which increases in depth as it moves towards the pylorus. When it reaches the pyloric vestibule the depression is so great that it almost completely divides the stomach into two parts, but the wave still moves on, and the division is absent in the intervals between the arrival of successive peristaltic waves. When death occurs during digestion the depression produced by a peristaltic wave may be fixed at the point where it happened to be at the moment of death: it is this depression which has been mistaken in anatomical preparations for a third sphincter.

The idea that there is a sharp separation between the chemical processes occurring in the two ends of the stomach is also incorrect. The food taken at the beginning of a meal reaches the pyloric end first, and that taken last is at first uppermost. Some hydrochloric acid, which is secreted mainly in the cardiac end, is carried with the first part of the meal to the pyloric end, where gastric juice and food are thoroughly mixed together by the peristalsis. It is now universally acknowledged (except by Mr. Gray) that there is no peristalsis in the cardiac end; consequently the peripheral part of the food is most acid and the central part may remain for a time alkaline and undergo salivary digestion (Grützner, Cannon). The moderately acid contents of the pyloric end, the very acid food in contact with the mucous membrane of the cardiac end, and the alkaline food in its centre are quite indefinitely separated from each other, as diffusion of the saliva and soluble constituents of the food on the one hand, and of gastric juice and products of gastric digestion on the other, must constantly and rapidly take place, and the movements of the diaphragm, abdominal muscles, and body as a whole all help to mix together the contents of the different parts of the stomach.

I should be glad to know the names of Mr. Gray's "recent radiographers and others" who "assert that the pylorus during gastric digestion descends naturally below and to the left of the umbilicus." In normal individuals I have never seen it either below or to the left of the umbilicus, and all the recognised authorities on the subject, including Barclay, Pfahler, Rieder, Holzknecht, Leven and Barret, Censé and Delaforge, are in agreement with me.

And who are the "recent radiographers" who say that "carbohydrate food begins to pass through the pylorus (displaced as described) in 15 to 20 minutes, and proteid in 30 to 45 minutes"? These are the figures given by Cannon as a result of his observations on cats, but it is now admitted by all who have examined human beings with the X rays that food, whatever its nature, begins to pass through the pylorus at once, and that a considerable quantity can be seen in the small intestine—and even sometimes in its pelvic portion—within a quarter of an hour. Yet Mr. Gray states that the times quoted are "the times when he observes food beginning to pass through the 'middle sphincter,' and he gravely suggests that "these gentlemen (i.e., 'the radiographers and others') mistake the 'middle sphincter' for the pylorus"! What Mr. Gray mistakes for a middle sphincter is beyond my power of imagination.

I quite fail to understand how the relief of hunger pain is evidence in favour of a middle sphincter. If it really prevented the access of food into the pyloric end of the stomach the eating of more food ought to be without influence on the pain. As a matter of fact, I have been able to demonstrate to the satisfaction of Mr. Moynihan [1] that food leaves the stomach with unusual rapidity in cases of duodenal ulcer, and that the delay in the onset of pain is not due to food being held back by the pylorus or by Mr. Gray's sphincter. My observations are confirmed by Barclay, who states that "the picture of a normal stomach exhibiting excessive peristalsis and passing the food on very rapidly is always suggestive of trouble in or about the duodenum."

Mr. Gray can never have seen intestinal segmentation or the interesting appearances recently described by Dr. Barclay of "blobs of food" dropping into the lower part of an atonic stomach, or he would not have rejected the entirely satisfactory explanation offered by Dr. Barclay himself, and made the extraordinary suggestion that the latter is due to segmentation, to which it does not bear even the remotest resemblance.

I am, Sir, yours faithfully,

Weymouth-street, W., Dec. 5th, 1910. ARTHUR F. HERTZ.

THE OWNERSHIP OF MEDICAL PRESCRIPTIONS.

To the Editor of THE LANCET.

SIR,—The law has been declared by an eminent official to be "a ass"; it is comforting therefore to find that it may be occasionally in accordance with common-sense. I think that the opinion on the subject of prescriptions given by Mr. H. Wippell Gadd [2] may, on the whole, though it is not quite free from ambiguity, be so designated. It is gratifying to have legal authority for the tenet that the purpose of a prescription is "limited in time as well as in person." The ambiguity lies in the statement that the prescription, though conditionally, "becomes the absolute property of the person who has paid the fee." What is the meaning of "prescription" here? Is it merely a piece of paper or is it an instrument that can be used for further purposes? It seems to me that there is some analogy between a prescription and a cheque. A cheque is written to empower a banker to pay a certain sum of money to a certain person; a prescription is written to empower a chemist to prepare a certain medicament for a certain person. When the cheque has been presented and cashed, it becomes invalid and useless; it is retained by the banker though it remains the property of the drawer and may be returned to him if required as a voucher of receipt. When a prescription has been made up, the document is sometimes retained by the chemist, but is usually returned to the patient. If it were still of any use to the prescriber I have no doubt that he would claim it and have it restored to him; but it would be to him valueless, only waste paper. There is some reason for the chemist to retain it, in case any doubt might arise as to the correctness of the writing or of the dispensing of it, although a copy, which he usually makes, is almost always sufficient. But on the whole, unless it be destroyed, it is perhaps best for the patient to retain the document (though he must be prevented from misusing it), as he may want it made up first in one place and then in another before its period expires, when it becomes as useless as the cashed cheque. Also he may sometimes have occasion to refer to it on subsequent occasions—e.g., to show to another medical man what treatment he had received before. For instance, some time ago I was treating a patient with pot. iodid. in moderate doses with moderate success; he told me that he had previously derived much benefit from very large doses. I acted on the hint with complete success.

I think that Mr. Gadd suggests the best road out of the difficulty, and one which, if generally followed, will lead to success. The proper way to limit the time of the prescription (after which it is, or should be, as dead as a cashed cheque) is, I believe, that which I have adopted for some time and to which I alluded in a letter published in

[1] B. G. A. Moynihan: Duodenal Ulcer, p. 108; London, 1910.
[2] THE LANCET, Oct. 1st, 1910.

THE LANCET on Oct. 31st, 1908—viz., to print conspicuously on the face of every prescription, "Not to be repeated after ..... days." This seems to be quite in accordance with Mr. Gadd's ideas, when he speaks of "the directions on the face of a prescription" which pharmacists would "respect and faithfully observe." This direction of a time-limit ought, I maintain, to be given on every prescription. If generally adopted its propriety would be readily acknowledged. A direction, "Rep. ad lib.," would be an exception. Limitation as to time would also almost entirely prevent transference of a prescription to others—e.g., in such a case as this: A patient has a prescription given to him (or her) by a physician in England; he afterwards comes to Australia and has it repeatedly made up there and distributes it among his (or, of course, usually *her*) friends, some of whom it may suit, others may be unaffected, to others it may be noxious. Thus it would be hardly necessary to express a limitation to the individual patient on the face of the prescription.

If a prescription is seized and made improper use of by a quack the way to deal with such action is by an Act for the suppression or limitation of quackery. There is another point wherein I think that prescriptions should be improved by greater strictness. Instead of having a mere unrecognisable hieroglyphic representing the initials of the prescriber, who is possibly and probably quite unknown to the dispenser, his name, titles, and address ought to be written or printed plainly on the face of the prescription, so that he may be identified. I am, Sir, yours faithfully,

F. LUCAS BENHAM, M.D., B.S. Lond., M.R.C.P. Lond.

Exeter, South Australia, Nov. 1st, 1910.

POLYDACTYLISM AND HEREDITY.

To the Editor of THE LANCET.

SIR,—The following cases of polydactylism may be of interest to your readers. A woman, aged 40 years, who had an extra finger on each hand and an extra toe on each foot, had six children, all girls. Five of these showed the deformity in a greater or less degree. Given in order of age they were affected: (1) right hand and left foot; (2) both feet; (3) both feet and both hands; (4) both feet and both hands; (5) right hand and left foot; the sixth child showed no signs of deformity, and there was no history of any of the relatives of either the mother or father having showed signs of the condition. I am, Sir, yours faithfully,

South Shields, Dec. 3rd, 1910. A. BANKS RAFFLE.

INVALIDITY INSURANCE.

To the Editor of THE LANCET.

SIR,—The question of invalidity insurance for the industrial classes is very much in the public mind just now owing to the announcement that the present Government, if returned to office after the election, will introduce such a scheme in the next session of Parliament; and while it is not my purpose to contribute directly to the discussion of such a scheme, indirectly some facts, which have emerged in the course of my own experience, may prove of more than passing interest to medical men.

It is a striking fact that while mortality is improving invalidity is increasing. The improvement in mortality has been accounted for as follows: (1) the increased protection afforded to infant life; (2) the improvements in sanitary science, which have done much towards averting epidemics and enabling communities to deal more intelligently and efficiently with them when they occur; and (3) the great advances in medical and surgical skill, and the improved treatment of sick at home and in hospitals, which have saved vast numbers from attacks which would otherwise have proved fatal.

The natural conclusion to be drawn from the improvement in mortality would be that there was also less sickness, but it is an indisputable fact that sickness is actually on the increase. It may be that knowledge of the science of public health is teaching men to take precautionary measures, and that one result of these precautions is that people now lie up where previously they would have continued at work. On this assumption there would obviously be, in the first place, an increase in the rate of sickness, and, in the second, a reduced rate of mortality, if only on the principle that "a stitch in time saves nine."

The company with which I am associated originated a system of sickness insurance for professional and business men some 25 years ago, and has therefore acquired a somewhat unique experience in this department, and the privilege I enjoy of access to their records has enabled me to compile some valuable figures, which go to show that one week of sickness benefit per annum becomes payable to every member assured between the ages of 20 and 35. Between ages 45 and 50 this payment is increased to two weeks per annum. Between 55 and 60 it works out at over four weeks per annum, and between 60 and 65 to over six weeks per annum. Then nearly 25 per cent. of the members assured are incapacitated for one week at least in each year between the ages of 20 and 40, and this increases steadily until it reaches 40 per cent. between the ages of 60 and 65.

Another feature brought out by an examination of the experience referred to is that of the average number of weeks' pay made to each member who is sick during each year. From 20 to 25 this amounts to nearly four weeks; from 40 to 45 the duration has grown to rather over six weeks; from 50 to 55 it is more than nine weeks; and from 60 to 65 the average duration of sickness is just under 16 weeks.

These figures tell their own story, one part of which is that no system of invalidity insurance can be thoroughly sound unless either the rates of premium increase with the increase in age, in which event they would be prohibitive in the later years of life, or, secondly, a fixed premium is charged. This, like a life premium, must be something more in the early ages than is required for the claims at those ages, the balance being accumulated securely at compound interest, so that the heavier sickness of later life may be met out of this source without an increase in the annual contribution. I imagine that both actuaries and medical men will watch with great interest a development so interesting as that foreshadowed in the Government programme.

I am, Sir, yours faithfully,

W. A. ROBERTSON, F.F.A.,
Actuary, Century Insurance Company, Edinburgh.

Nov. 25th, 1910.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—The remarks which you kindly made in reference to my work in Suffolk in connexion with the epizootic of plague on p. 1568 of your issue of Nov. 26th err in one particular. In fairness to the gentleman holding the post I ought to tell you that I am not the assistant medical officer of health for Ipswich. Prior to the appointment of an assistant I undertook the work of the medical officer of health in his absence, but now, apart from my appointment by the East Suffolk county council, the only official position I hold is that of bacteriologist to the East Suffolk and Ipswich Hospital.

I am, Sir, yours faithfully,

Ipswich, Dec. 2nd, 1910. H. LLEWELLYN HEATH.

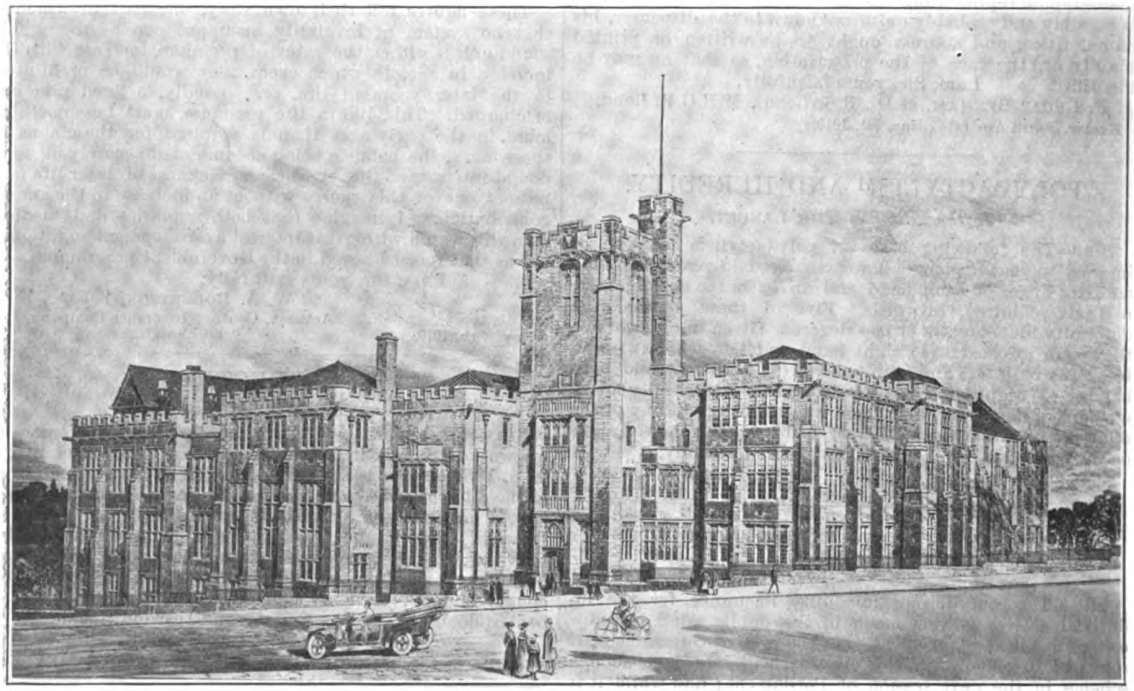
METROPOLITAN HOSPITAL SUNDAY FUND.—Under the presidency of the Lord Mayor, the Right Hon. Sir Thomas Vezey Strong, a council meeting of this Fund was held at the Mansion House on Nov. 30th, when the report for the year 1910 was ordered to be published. The report states that the total collection amounted to £71,550, of which £40,778 were collected in places of worship, £1635 more than in 1909. On the motion of Archdeacon Sinclair, the sum allotted by the Fund to the purchase of surgical appliances was raised from 5 per cent. to 7½ per cent. Referring to the subject of cinematograph shows, Archdeacon Sinclair said that pending the appeal in a certain case by the London County Council with regard to the licensing of these exhibitions, the Fund could not arrive at a decision with regard to these shows being held on Sundays for the benefit of hospitals. He thought, however, that the subcommittee which had the matter in hand would arrive at a satisfactory decision. It was agreed by the council to recommend that the sum of £100 should be voted to the secretary, Sir Edmund Hay Currie, who is suffering from bronchitis, to enable him to take a holiday abroad, and the sum of £20 towards a testimonial to Mr. Cole of the Christian Evidence Society. The annual meeting of the Fund will be held on Dec. 16th.

THE NEW WING OF THE UNIVERSITY OF BRISTOL.

(FROM OUR SPECIAL CORRESPONDENT.)

THE large block of buildings which has just been completed and equipped at a cost of £50,000 was formally opened by Lord Winterstoke, Pro-Chancellor to the University, on Nov. 15th, and is a splendid pledge of the firmness with which those in authority mean to establish the University of Bristol. It is designed to hold the departments of chemistry and physiology, which have till now occupied inadequate quarters in the old building. The money has been provided by the £100,000 subscribed by Mr. H. O. Wills, the Chancellor of the University, out of which five chairs have also been endowed. The site is part of that obtained by purchase of the Blind Asylum and its grounds, and it adjoins that of the other buildings so closely that it has been possible to make the corridors of the older north wing continuous with those of the physiological section of the new wing. Further extensions are to be expected next year when the occupants of the Blind Asylum move. It should be remarked that the transference of physiology and chemistry from the old buildings to the new has set free much space for the use of other departments.

FIG. 1.



General elevation of the new wing of the University of Bristol.

Physiological department.—The designs for this department are the result of a careful examination of the physiological buildings of other universities. Professor A. F. Stanley Kent, in many instances in conjunction with the architects, has visited Oxford, Cambridge, Edinburgh, Glasgow, Manchester, Liverpool, Leeds, Sheffield, Strasburg, Freiburg, Nancy, and Lausanne. The accommodation thus provided is mainly in that part of the building which lies to the right of the tower in the accompanying elevation. (Fig. 1.) On the ground floor is a lecture theatre which will seat 150 students, with specially designed folding screens to carry diagrams, illuminated by electric light focussed on them. There is also an electric lantern for use with lantern slides, and a Zeiss electric projection apparatus for showing microscopical specimens. Adjoining this theatre are the professor's room, a museum and library, and a good preparation room. On the first floor the chief room is a students' laboratory of chemical physiology, illustrated in Fig. 2. Close to this is a large preparation room, with store and dark rooms; and another room on the same floor is devoted to the study of physiological optics, vision, photo-micrography, gas analysis, &c. On the second floor there is a large histological laboratory, in which a weaving-shed glass roof has been adopted in order to provide the maximum amount of illumination without allowing the direct entrance of sun rays. The accommodation in this room is increased by the addition of a gallery, in accordance with the plan followed at Cambridge. On this floor there are also a preparation room for histology and a large laboratory for the study of experimental physiology in the preparation room for the same purpose. At a little distance from these rooms, but still on the same floor, there are a demonstration theatre with a good top light and a preparation room serving it. A galvanometer room, a research laboratory for the professor, and a small store are also situated on the second floor. Finally, in the basement are a room for the study of cardiac physiology, a subject with which Professor Stanley Kent's name is closely associated, a dark room, a constant temperature room, an incubator room, and a cold store. This department is therefore admirably equipped, not only for the teaching of elementary and advanced physiology in all its branches, but also for research.

Chemical department.—This department, consisting of a basement and two floors, contains working places for 200 students. In the basement are the main stores communicating by a lift with the preparation rooms for the lecture theatre and senior laboratories on the ground floor, and with the store room for the main laboratory on the first floor. The basement also contains a laboratory accommodating 20 students, specially arranged for candidates for the Diploma of Public Health and those studying the methods used by analytical chemists. In addition to special rooms for gas analysis and photo-chemistry, the main feature of this floor is a large metallurgical laboratory, provided with heavy electrical currents for electro-metallurgical investigation. The ground floor contains a lecture theatre seating 150 students (a magnificent room) and a lecture room, each having its own preparation room. There is also a museum containing, among other things, a very complete collection of synthetic dyes. The senior laboratories and balance room are on the same floor, and the professor's private room and laboratory

divide the organic laboratory from that for physical chemistry, so that the professor is in close touch with his advanced students. On the first floor the principal room is the junior laboratory (Fig. 3), in which 80 students can work at the same time. There is a chemical library on the same floor, also a small laboratory specially designed and equipped for the investigation of problems connected with agricultural chemistry.

FIG. 2.

The Laboratory of Chemical Physiology.

General design.—The new wing is as large as the block of buildings which has up to now served all the departments of the University excepting those of the Faculty of Medicine. As has been already mentioned, it is continuous with the old block, the ground floor of the one communicating directly with that of the other; but the new wing is on sloping ground and at a slightly lower level than the old wing. It is this circumstance which has made possible the construction of a well-lighted basement. The new wing provides the University with a new frontage on Woodland-road, on the other side of which the new Baptist College (itself in affiliation with the University) is to stand. The main entrance from this side is at the foot of the tower; it opens upon the staircase running up from the basement to the tower and supplying both departments. Each landing communicates with two corridors, one running through a floor of the chemical department and the other through a floor of the physiological department. Architecturally it is an imposing pile of buildings, and the tower is a striking feature in a city of towers and spires, for the University stands on the slopes of a hill near the summit at which the fort of Prince Rupert's time stood, and overlooks the western half of the city. The external walls are of red pennant stone, and Box ground stone has been freely used for the dressed stonework. The floors, which are fireproof, are of steel and concrete; in some instances armoured concrete has been used. For the most part the internal partitions are capable of removal without involving constructional changes. The joinery is of Oregon pine, oak having been used to a small extent. The buildings are warmed throughout with hot water upon the low-pressure principle with accelerated circulation, Haden's patent "Turbo" accelerator being used. The building is lighted very thoroughly throughout by electricity, and all the laboratories are wired for experimental purposes. The ventilation is effected by means of powerful fans; the main fan is situated in the upper portion of the tower. Several systems of draught flues are also provided in connexion with the various benches, fume cupboards, and other fittings in the laboratories, each of them having its own fan.

The general solidity of the building and the harmonious scheme of external design reflect the greatest credit on the architects, Messrs. Oatley and Lawrence of Bristol. The works have been carried out in less than 12 months by the builders, Messrs. Cowlin and Son, also a Bristol firm. The whole building is manifestly the outcome of a generous conception of the functions of a modern university, coupled with efficient and laborious execution of details; and it pledges those who control the general policy of the University, both now and in the future, to large ideas and thorough work. The photographs, specially taken for THE LANCET, are by Mr. Frank Marsh, Whiteladies-road, Clifton; the plan of the elevation was kindly lent for photographic purposes by the architects.

The Junior Chemical Laboratory.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Workhouse Accommodation.

THE various boards of guardians of Manchester are still discussing the best way of lessening the overcrowding of their hospitals. In the Manchester township last week the question arose as to whether or not the guardians had the power of detaining cases of "pulmonary tuberculosis with expectoration." Notwithstanding the reply of the Local Government Board to an inquiry from South Stoneham, that it could be done under Section 22 of the Poor-law Amendment Act, 1868, the clerk said that no board of guardians or any other authority had power to detain a case of consumption, while one member of the board remarked, "the guardians are absolutely powerless in one of the most appalling parts of their work." At the meeting of the South Manchester guardians on Nov. 25th the overcrowded state of the children's ward at the hospital was brought up. The workhouse committee had recommended that a children's hospital should be built with 300 beds, and so arranged as to be easily extended. This was discussed *pro* and *con.*, but on the motion of Mr. F. B. Hargreaves was referred back. He said that many of the beds were occupied by cases which ought not to be there. Another difficulty they have to contend with is the number of phthisical cases under their charge. At present there are 141 male and 77 female consumptives, while there was only provision made for 96 men and 36 women. Dr. T. N. Orchard said that 59 cases were distributed among other wards. There was no isolation of phthisis. Dr. Garrett, another medical guardian, took a more serious view apparently than his colleague, and there can be no doubt that there is overcrowding both of children and consumptives, and no time should be lost in remedying the evil. In the Prestwich union they are troubled with an excess of lunatics, who are not fit to go out and for whom no room can be got elsewhere. No help is to be obtained from the Prestwich Asylum, for that is also overcrowded. All this reveals a very serious state of affairs.

Value of Light.

November is a dark month at the best, and if, as in Manchester, the darkness is intensified by the black pall of smoke that broods over the city, it only needs the addition of an atmospheric fog to convert the city into something terror-exciting, something only fitted for the wanderings of lost souls. The Manchester and Salford Sanitary Association and the Smoke Abatement Society have done what they could to lessen the production of smoke, but without making any very great impression on conditions due to such complicated causes. On Dec. 2nd a deputation from the former society interviewed the gas committee of the corporation with the view of obtaining a reduction in the price of gas, as the increased use of gas will modify the production of smoke. Mr. T. C. Horsfall urged that in Manchester the people were debarred from the agency of fresh air and light owing to the prevalence of smoke and fog, which were highly detrimental to the healthy development of the citizens. The deputation had come to beg the committee to encourage the use of gas in place of the small smoky fires by a reduction in its price. Sir Alfred Hopkinson, Vice-Chancellor of the University of Manchester, supported these views, and hoped that the magistrates would deal with gradually increasing severity with those responsible for the production of black smoke. Others of the deputation spoke, but without producing any very perceptible impression on the chairman of the gas committee. He was sympathetic, but pointed out that he had to find £50,000 a year out of the gas profits for the relief of the rates. It is a question worth considering whether it would not be more economical in the long run to improve the public health by spending this money in cheapening the price of gas rather than in relieving the rates, which relief, by the way, is shared by the non-users of gas. An improved public health is a splendid economy for a community.

"Slink" Meat.

There must be a roaring trade in "slink" meat in our large towns if what came to light in Preston the other day may be taken as a fair illustration. During the past few weeks no less than 7106 pounds had been ordered to be destroyed by the meat inspector. Dr. Brown, chairman of the health committee, said that a large amount of the meat was brought into the town, but the authorities knew those who dealt in doubtful meat, all of which was strictly inspected. In Cheshire there are, or were quite recently, men who were well known to be nothing but "slink" butchers. They apparently went openly about their business, none making them afraid, which looks as if the present legal prosecutions against the sale of bad meat were insufficient.

Plague Precaution.

It is satisfactory to know that our local authorities are keenly alive to their responsibilities. At the last meeting of the port sanitary authority the medical officer, Mr. W. F. Dearden, reported that in compliance with the requirements of the Local Government Board he had instituted an inquiry as to the extent to which the wharves and warehouses of the port were infested with rats and the methods adopted to keep down their number. He had been assisted by the general superintendent of the Ship Canal Company. It was ascertained that since the practice of keeping cats in the warehouses had been adopted the number of rats had been considerably kept down; that they were very seldom noticed in the transit sheds, and that no dead rats were found among cargo. The Ship Canal Company and all others concerned had been warned to keep a sharp look-out for dead rats, and to advise the medical officer of any unusual mortality among them. If rats were absolutely exterminated, which is a very distant possibility, the purpose of their existence might be revealed to us. Their disappearance, it seems, would result in no dangerous disturbance of Nature's scheme, but is it not certain that the pulex would then find another host?

The Manchester Hospital for Incurables.

The annual meeting of the Manchester Hospital for Incurables was held on Nov. 30th. There are two homes devoted to this work, one at Mauldett, Heaton Mersey, and the other at Walmersley House, near Bury. Of these patients 102 are free, while there are 16 for whom full or partial payment is made. There are also 12 pensioners who receive £20 a year. Those who visit the homes testify to the comfort and to the surprising cheerfulness of the patients, for whom the prospect must be inexpressibly sad. Being a most useful and humane, as well as a charitable institution, one looks, unfortunately, but too often quite as a matter of course, for an adverse balance-sheet. In this case, happily, it is not more than £335. All should sympathise in such work and the deficit ought immediately to be wiped out.

Dec. 6th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Treatment of School Children.

IN spite of the powers given to local education authorities by Section 13 (*b*) of the Education (Administrative Provisions) Act, 1907, to make arrangements for attending to the health and physical condition of children educated in public elementary schools, few authorities have made use of their powers. As a result a large number of children found defective on medical examination are being treated in the general hospitals. The governing bodies of a few of these institutions have protested, more or less successfully, against the adoption of this course. The latest to do so is the board of management of the Herefordshire General Hospital, who passed a resolution on Dec. 3rd that after June 30th, 1911, such children would not be eligible for treatment at the hospital. This decision was arrived at after the board had considered a memorandum which had been drawn up by the medical staff of the hospital. In that memorandum it was pointed out that the object of voluntary hospitals should be to relieve that large body of poor people who were just above those whom the local authorities were empowered by the Legislature to treat out of public funds, and yet who were not in a position to pay for special or costly treatment by their own medical man. It was further pointed out that neither the money of subscribers nor the endowments of hospitals were ever intended to relieve the rates by doing the work either of the Poor-law or education authorities, so that these bodies, in attempting to make use of such a charity as a hospital

to meet their responsibilities, were apparently hoping that custom would in time force upon the hospital authorities the duty of providing for these patients. An attempt was thus being made to make one class of the community work for the rest without payment, and in the opinion of the medical practitioners in the county such an attempt should be resisted. As regards the right of the board to refuse admission to those children who presented letters of recommendation from subscribers, the staff reminded the board that already restrictions existed and that treatment was refused to parturient women, consumptive patients, infectious cases, cases for dental treatment (except for extraction), and lunatics. The memorandum concluded by stating that by continuing to treat these children, whose treatment should be paid for by the State, the board would be incurring the hostility of the general practitioners in the county, some of whom had repeatedly reproached the hospital staff for assisting in the carrying out of such gratuitous treatment as that indicated.

The Inspection of School Children: a Parent Fined.

At the Bridgwater county petty sessions held on Nov. 28th a man was charged "with having wilfully neglected his daughter, aged 7 years, in a manner likely to cause her unnecessary suffering, or injury to health, including injury to eyesight." Evidence showed that the defendant, who resided in a neighbouring village, had been given repeated notice to send his child to Bridgwater to be examined by the ophthalmic surgeon of the Somerset education committee, the girl's eyesight being very defective. The defendant ignored every notice sent to him, and medical evidence showed that spectacles were urgently required. A fine of £2 and costs was imposed. This is the first prosecution of the kind instituted by the Somerset county council.

The Care of Imbeciles.

At a meeting held at Devizes on Nov. 21st, when representatives of nearly all the Wiltshire guardians were present, it was decided to approach the Local Government Board with the suggestion that special institutions, distinct from asylums, should be provided, in which all imbeciles should be treated. Mr. Thompson, the Local Government Board inspector, who was present, stated that the Local Government Board would give every assistance in promoting the scheme. After some discussion a deputation was appointed to interview Mr. Davey at the Local Government Board upon the matter.

The Didworthy Dispensary for Tuberculosis and Diseases of the Lungs, Plymouth.

The Didworthy Dispensary for Tuberculosis which has been established in Frankfort-street, Plymouth, was opened on Dec. 5th. The institution is for the poor and needy, and no ticket of recommendation will be required, the medical officer giving gratuitous service. Early cases of consumption will be sent to Didworthy, whilst advanced cases of the disease will be followed up at their homes by nurses. The financial support of the dispensary has been satisfactory, and up to the present about £160 have been received, which will be sufficient to carry on the work for the first 12 months. The Earl of Mount Edgcumbe has given £20 and Mr. Waldorf Astor £100, with an additional £100 for the distribution of literature bearing upon tuberculosis.

Workhouse Accommodation in Carnarvon Union.

The accommodation for the sick in the Carnarvon union has for a long time been unsatisfactory. Little or no classification is at all possible, so that consumptives, imbeciles, and other cases of sickness are treated in the same building. The only way in which real improvement can be effected appears to be by providing a new infirmary with modern equipment, and at a recent meeting of the board of guardians this course was urged by Mr. Hugh Williams, the Poor-law inspector for Wales, and Mr. B. T. Kitchen, the architect of the Local Government Board. Several guardians, however, advocated certain alterations to the existing infirmary building, and by a majority of three votes this proposal was adopted. At a further stage of the meeting it was decided to postpone the whole matter indefinitely in view of possible legislation with regard to the administration of the Poor-law generally. It is hardly likely that the Local Government Board will be satisfied with this unsatisfactory conclusion. The Abergavenny board of guardians has been threatened by the central authority with dissolution unless it provides better accommodation for its sick poor, and if the same course were adopted with respect to the Carnarvon board the members might perhaps reconsider their ill-advised decision.

Medical Officer of Health for Cardiganshire.

The county council of Cardigan has decided to appoint a medical officer of health at its meeting in February next. The salary has been fixed at £450 per annum, and the person appointed is to pay his own travelling expenses. The duties of the office will include those of school medical officer, and candidates for the appointment must be able to speak Welsh. Inadequate as this salary is, an attempt was made, though without success, to reduce it to £400 per annum. The population of Cardiganshire at the last census was 60,237, and the area is 440,630 acres.

Bristol Medical School Dinner.

The annual dinner of the Bristol Medical School was held on Nov. 29th at the Royal Hotel, Clifton, under the presidency of Mr. James Taylor. The guest of the evening was Sir Alfred Keogh, and there was a large attendance. Sir Alfred Keogh, who received a most enthusiastic reception, in the course of an interesting speech dealing with the work of the Royal Army Medical Corps, stated that he considered the Royal Army Medical Corps was highly efficient and doing a great work for science.

Death of Dr. Richard Mathias.

Through the death on Nov. 22nd of Dr. Richard Mathias of Radyr, near Pontypridd, a promising career has been prematurely cut short at the early age of 42 years. Graduating in arts at Cambridge in 1893, Richard Mathias later entered the medical school of Guy's Hospital and took the double qualification of the London Colleges in 1896, subsequently graduating in medicine at his university. In 1899 he succeeded to a practice at Radyr and Taff's Well, a district situated midway between Cardiff and Pontypridd. His family connexions were largely interested in the industries of the locality, but, quite apart from any advantage which this might be to him, his professional skill soon secured for him the confidence of his patients, while his kindliness and generous thoughtfulness for others made him popular with all classes. He leaves a widow and one child to mourn their loss.

Dec. 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Voluntary Health Visitors of the City of Edinburgh.

THE question of the prevention of infantile mortality has been vigorously taken up in most of the large cities of the kingdom, and many organisations have arisen the object of which is the remedying of this evil. Among these, the body known as the Voluntary Health Visitors of the City of Edinburgh takes a high place, both on account of the results of the work and the efficiency of the organisation. In the beginning of 1908 the Charity Organisation Society appointed a subcommittee to consider the various possible methods of dealing with infantile mortality in Edinburgh, and as a result, with the coöperation of the medical officer of health, the band of Voluntary Health Visitors was organised and began work in the end of 1908. The work, though voluntary, is done in connexion with the Public Health Department and under the inspection of the medical officer of health, Dr. A. Maxwell Williamson. When the work was taken up the public health committee of the town council appointed one salaried health visitor, whose duty it is to pay the first visit as soon as possible after notification of the birth. Only the very poor families are visited—of the class in which there is no family doctor. After the first visit has been paid the official health visitor hands on the name of the case to the secretaries of the voluntary health visitors, and then these visitors undertake the supervision of the infant for the first year of life. The visitors now number between 250 and 300, and the cases under visitation number over 1590. The city is worked in 70 districts, the visitors being supervised by captains who have charge of one or more districts, the whole work being organised by the honorary secretaries, Mrs. Somerville and Mrs. Hamilton Maxwell. The visitors are supplied with printed forms on which they fill in particulars as to

tne condition of each infant under their care. They are required to report in this way fortnightly, the forms being sent in to the medical officer of health. Infants of Roman Catholic parents are undertaken by Roman Catholic visitors, and Protestants by Protestant. When the work was initiated it was endeavoured, so far as possible, to make use of visitors already at work in the district, their numbers being supplemented whenever necessary. In spite of the tradition that the work of voluntary workers cannot be depended on to last, the character of the work of the voluntary health visitors of Edinburgh has, on the whole, improved in quality during the two years of their existence. Notwithstanding the very considerable amount of trouble involved in the visiting and in the filling up and sending in of the fortnightly reports the work is being done with commendable regularity, and in only a small number of cases has the reporting been done irregularly. The credit of this must partly be given to the able manner in which the honorary secretaries organise the work and keep alive the interest of the visitors in the scheme. Short courses of lectures are arranged for the visitors during the year. The lecture courses for this winter are: (1) a preparatory course of six lectures by Mrs. B. Russell, L.R.C.P. & S. Edin., M.D. Brux.; (2) a short course of lectures, by Dr. R. W. Philip, on Tuberculosis; and (3) five lectures, by Mrs. George Kerr, honorary secretary City of Edinburgh Charity Organisation Society, on Training for Service. A fee of 2*s.* 6*d.* is charged for each course of lectures. Small handbooks are given to the visitors, furnishing information with regard to medical and other charities in the city, the aim being to educate the visitors in all matters touching their work. The expenses to the city of the Voluntary Health Visitors amounted in 1908 to between £11 and £12. This sum did not include stationery which was supplied by the Public Health Department. The fees to lecturers were defrayed by the sale of lecture tickets to the visitors. The expenses to the city this year will amount, it is expected, to not more than £20, the increase being partly due to the increase in the work and partly to the expense of the forms for the fortnightly reports, which were introduced since the beginning of the year. For the amount of work done—the visiting and fortnightly reporting on nearly 1600 infants—this expense is remarkably small, and is interesting as showing what resources in the way of purely voluntary work may be called into activity provided efficient organisers are found. Edinburgh is rich in hospitals and dispensaries and visitors are kept well informed as to where they may send their cases for medical and surgical advice. A weekly consultation is held in connexion with the out-patient department of the hospice where visitors may send infants to be weighed, and two of the voluntary health visitors undertake to weigh at their houses infants who cannot be taken out for this purpose. At the hospice a milk depôt is worked on a small scale. In connexion with the Voluntary Health Visitors' organisation a cradle committee manufactures cradles out of banana crates, which are sold to the mothers at 1*s.* 6*d.* each, and another committee provides baby clothing which is sold to the people at low rates, and cooking classes are arranged for the mothers. A fortnightly visitors' meeting lasting for one hour is held in the City Chambers, when reports from the various committees and from the hospice are read. The secretaries also endeavour to arrange for a short address to be given at each meeting on some particular branch of social work. As to the results, the only figures yet available are those relating to the first year of the work, 1909, as given in the annual report of the medical officer of health. Infantile mortality in Edinburgh has never reached so high a figure as in many of the large manufacturing towns. In 1908, before the present work was begun, the rate was 114 per 1000 births. In 1909 the rate fell to 113. At first sight the decrease was small, but, as Dr. Maxwell Williamson pointed out when addressing the visitors on the subject, the rate was undoubtedly kept up in 1909 by a high mortality from zymotic diseases, notably in pertussis. In the deaths classified as due to diarrhœal and digestive disorders, in which direction, presumably, the effect of the work of the health visitor would most clearly be seen, there was a marked reduction, the figures being 77 deaths in 1909, against 113 in 1908, while the deaths under one year classified as due to starvation, malnutrition, atrophy, debility, and marasmus fell from 111 in 1908 to 75 in 1909. In the areas marked by the medical officer of health as being those in which the conditions were most adverse, and where the mortality in 1908 was calculated as 160 per 1000 births, there was a reduction in 1909 to 154 per 1000 births, while deaths from overlying, which numbered 18 in 1908, fell to 11 in 1909. In the present year the mortality so far has been under 100 per 1000 births, and unless in the last two months of the year there is an unusually high death-rate the figures for the year should show great improvement.

Statistical Report of Glasgow University.

The secretary of the University Court has just issued the report of statistics, &c., relative to the University of Glasgow for the academical year from Oct. 1st, 1909, to Sept. 30th, 1910. The report shows that the teaching staff consisted of 32 professors, 54 lecturers, and 88 assistants and demonstrators. The salaries paid to the principal and professors amounted in all to £26,512 7*s.* 1*d.*, to lecturers £8217 4*s.* 8*d.*, and to assistants and demonstrators to £9747 3*s.* 10*d.* Pensions amounting to £4935 2*s.* 6*d.* were paid to retired professors. During the year the total number of matriculated students was 2728 (including 642 women), as compared with 2699 (including 695 women) for the preceding year. Of these 1264 (including 534 women) were enrolled in the Faculty of Arts, 449 (including 24 women) in the Faculty of Science, 61 (including 1 woman) in the Faculty of Theology, 701 (including 71 women) in the Faculty of Medicine, 204 in the Faculty of Law, and 49 (including 12 women) in a single class. The following degrees were granted in medicine:—M.D.: With high commendation, 2; with commendation, 4; ordinary, 9. M.B., Ch.B.: With honours, 3; with commendation, 7; ordinary, 84. The total degrees in medicine were thus 109.

Dec. 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Congress of the Royal Institute of Public Health.

THE Congress of the Royal Institute of Public Health is to meet in Dublin next summer, and a meeting of citizens was held last week in the Mansion House, under the presidency of the Lord Mayor, to make preliminary arrangements. An influential local committee was formed, and it was decided to invite Lord Iveagh to accept the presidency of the congress. No better choice could have been made, for Lord Iveagh, besides being head of Messrs. A. Guinness and Co., the greatest employers of labour in Dublin, has shown a practical interest in the housing of the poor both in Dublin and London. He has provided the funds for clearing various slum areas and substituting modern blocks for the old rookeries.

Dublin City Bacteriologist.

A position of some interest has arisen in connexion with the appointment of a bacteriologist for the city of Dublin. The choice of the corporation fell on Dr. M. J. Russell, medical officer to one of the city dispensaries. The appointment is, however, subject to the sanction of the Local Government Board, and this has been refused. In a letter to the corporation the Local Government Board remark that Dr. Russell, owing to other engagements, "could not be in a position to undertake the very responsible duty of advising the corporation of Dublin on a subject which requires close and unremitting work in the laboratory;" and that "it it is, in the Board's opinion, essential that if the person appointed is to command the confidence of the public and of the medical profession he should devote his time largely, if not entirely, to bacteriological work.

A Well-fought Election.

For some weeks past much interest has been taken in the neighbourhood in the election of a medical officer for Mountbellew Dispensary District in the county Galway. On two occasions the guardians met for the election, but on both the voting was equal between two candidates—Dr. O'Kelly and Mr. J. J. Egan. Only one guardian was absent, and one guardian who was sick was carried into the board room in a chair. The chairman has no casting vote, and therefore a third meeting had to be called. On this occasion there was a full board, and Dr. O'Kelly was elected by one vote. A

district inspector and eight constables were present to maintain the peace.

The Lord Chief Baron and Medical Evidence.

While summing up in a case heard before him last week the Lord Chief Baron Palles made some severe remarks as to the kind of medical evidence which, he believed, is given in the Irish courts. He said the conduct of the particular case had been very pleasant to him, for it was one arising out of railway injury but had not involved medical witnesses in that terrible difference of opinion which very often existed between them. Lord Chief Baron Palles is voicing the opinion of many members of the medical profession in suggesting that some of the "expert evidence" given in court is not creditable to the profession.

Royal Medical Benevolent Fund.

At the annual meeting of the Irish Medical Association in 1909 the president, Sir William Smyly, made an offer of a special donation of £20 to the Royal Medical Benevolent Fund on condition that at least half the medical practitioners of Ireland would contribute at the rate of one penny a week for the year 1910. At the meeting of the central committee of the fund last week the secretary had to report that only 790 out of 2200 medical practitioners in the country had contributed for the year 1910, and that the fund was therefore not in a position to claim Sir William Smyly's donation.

Belfast Board of Guardians.

At a meeting of the Belfast board of guardians, held on Nov. 29th, a strong resolution was passed protesting against the action of the Government in ordering a proportionate abatement of the sum payable in respect to the expenditure incurred by it for medical and educational purposes during the financial year ending March 31st, 1911. The guardians consider they are entitled to the standard amount of recoupment—in respect of medical and educational expenditure (£3942 16*s.* 11*d.*)—that has been paid in the past, otherwise the deficiency will fall on the ratepayers already overtaxed, or the guardians will have to give less assistance to the poor.

Health of Belfast.

The report of the medical officer of health of Belfast presented to the monthly meeting of the city corporation, held on Dec. 1st, showed that for the four weeks ended Nov. 12th 169 cases of infectious disease were notified, as compared with 121 in the preceding month, and 119 in the corresponding month of 1909. The increase applies to all notifiable diseases, the major portion being due to scarlet fever and erysipelas, of which 94 and 30 respectively were notified, as against 68 and 17 the previous month, and 61 and 27 in the corresponding period of 1909. 28 cases of tuberculosis of the lungs were notified. The epidemic of scarlet fever—though mild, fortunately—had so taxed the resources of the municipal fever hospital at Purdysburn that the board of guardians had to be asked to relieve the congestion by taking in cases to the union infirmary.

Ulster Medical Society.

At the second meeting of this society in this session, held in the Medical Institute, Belfast, on Dec. 1st, Dr. Cecil Shaw read a paper, "Making a Cure at a German Spa," illustrated by original photographs shown by the lantern. Mr. John O'Doherty read a paper on Tubercular Appendicitis and its Relation to Tabes Mesenterica. Dr. G. A. Hicks showed some specimens of Fibroid Tumours of the Uterus with Degenerative Changes.

Dec. 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Hypodermic Injection of a Mixture of Ether and Oil.

AT a meeting of the Therapeutical Society held on Nov. 23rd M. Gimbert spoke in favour of the hypodermic injection of a mixture of equal parts of ether and oil, the mixture to be made either at the time of using or else very shortly beforehand. He said that the puncture might be either subcutaneous or intramuscular, and that the operation was invariably very much less painful than the injection of ether by itself was to certain individuals; it might even cause no pain at all. Two cubic centimetres of the mixture might be given at a time, and this dose might be repeated from hour to hour. The principal action was that of a stimulant, the effect becoming apparent in from five to six minutes—i.e., perhaps less rapidly than with pure ether. The patient's pulse improved, he felt better, and had a sensation of warmth, the drowsiness and general distress diminished, and the respiration became regular.

Gynæcology in Madagascar.

At a recent meeting of the Société de l'Internat des Hôpitaux de Paris M. Fontoynont said that among the natives of Madagascar the cervix uteri frequently presented the peculiarity of a considerable hypertrophy of the anterior lip which might even extend as far as the vulva. This was, perhaps, a racial peculiarity, and it would be interesting to inquire if it existed among the Malays. Elephantiasis of the labia majora and labia minora was common; it was a result of syphilitic infection, and in appearance closely resembled elephantiasis of tuberculous origin, but differed from filarial elephantiasis. Coxalgia and Pott's disease were of extreme rarity. Gonorrhœal affections, although very prevalent, did not give rise to disease of either the uterus or the adnexa. The absence of restrictive measures and the desire to have children discouraged abortion, with the result that infections of the uterus and the adnexa due to abortifacient procedures were comparatively infrequent. Fibroma was not so common as in Europe; cancer of the uterus was rare, but was more often met with than cancer of the skin; cancer of the alimentary canal was quite unknown. Extra-uterine pregnancies formed the majority of the gynæcological conditions for which surgical operations were required. Malaria exercised an influence on most diseases; it might give rise to abortion, and the only way of preventing premature labour from this cause was the injection of quinine in a sufficient dose, such as a gramme or a gramme and a half.

Action for Damages against a Surgeon.

On Dec. 1st the Tribunal of the Seine decided a case in which a married woman claimed 50,000 francs damages from Dr. Bazy, who had operated on her in the Hôpital Beaujon for an abdominal cystic tumour in the year 1906. In the course of the operation, which was difficult and performed in circumstances of urgency, Dr. Bazy by an oversight left two cotton-wool compresses in the wound. The court was of opinion that he was to blame, but it had been proved (1) that the compresses thus left behind had not caused any material injury; and (2) that at the time of the operation the woman's health and even her life were seriously endangered; it was also very probable, if not positively certain, that without the operation she would not have been alive to-day. In these circumstances the court, considering a claim of 50,000 francs to be excessive, reduced the amount of damages to 5000 francs.

Treatment of Gonorrhœal Rheumatism.

In a communication made to the Société Médicale des Hôpitaux on Nov. 25th M. Louis Ramond and M. Chiray stated that five cases of acute or subacute gonorrhœal monoarthritis, which had been treated by the ordinary methods without benefit, had recovered completely under the use of the antimeningococcic serum of the Pasteur Institute. This serum was injected under the skin, either in the neighbourhood of the affected joint or at a distance from it, or even into the joint itself. A dose of 20 cubic centimetres was each time found sufficient to produce the almost immediate disappearance of the habitual painfulness of the part, the rapid absorption of the effusion both within and around the joint, and the cessation of the pain which had for a considerable time been felt on pressure. The serum treatment did not avert ankylosis in patients who presented themselves in a late stage of the illness, and the earlier it was applied the better prospect was there of the joint remaining useful. These cases fully confirmed the observations made by M. Pissavy and M. Chauvet, and showed that in gonorrhœal rheumatism injections of antimeningococcic serum were simple, effectual, and free from danger.

Action for Damages against a Pharmaceutical Chemist.

A recent decision of the Tribunal of the Seine has an important bearing on the responsibility of pharmaceutical

chemists in connexion with the treatment of patients. A woman cook who had injured her elbow by a fall went on the following day to a druggist, who gave her some preparation and strongly advised her to follow his treatment without consulting a medical practitioner. When eight days had passed without any abatement of the swelling the cook's mistress called in her own medical man, who found that the elbow was dislocated and that on account of the long delay it would be necessary to have a surgical operation, which was accordingly performed in two stages. The patient then brought an action against the druggist and was awarded 2000 francs damages.

Treatment of Syphilis.

At a meeting of the Société de Médecine de Paris held on Nov. 26th M. Lacapère said that the three principal remedial measures in use for syphilitic patients at the present time were as follows: (1) mercurial treatment, for which purpose he decidedly preferred the intravenous injection of soluble salts; (2) hypodermic injections of soluble mercurial salts, together with simultaneous injections of hectine, a method which has given excellent results; and (3) arsenical treatment, consisting in the intravenous injection of arsenobenzol in repeated small doses, a method of administration which was unquestionably superior to intramuscular injections.

Dec. 5th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Unqualified Practice.

THE various questions connected with unqualified practice continue to engage the attention of the medical profession in Germany, especially in view of the Bill on the subject which will be discussed in the present session of the German Parliament.[1] Dr. Reissig of Hamburg, writing to the *Berliner Klinische Wochenschrift*, gives some interesting particulars relative to unqualified practice. The authorities estimate the number of unqualified practitioners at about 10,000, but this is much too small, and the real number is believed to be between 12,000 and 15,000. The number of patients attended and the fees pocketed by certain quacks are truly enormous. Special trains are run by the railway companies to certain small places where celebrated quacks reside; an instance of this kind is provided by a shepherd named Ast, who lives near Hamburg, and attends as many as 500 patients a day. In other cases where the residence of the quack is at some distance from a railway station, a motor-car or omnibus service is provided for the conveyance of patients to his house and back to the station. Some quacks attend 20,000 patients a year, in addition to consultations and advice by letter. In an action-at-law brought against a quack named Norden-Köther, who had formerly been a chemist, his annual income from patients was stated to be 240,000 marks (£12,000). Several practitioners of the same description have incomes of more than 100,000 marks (£5000), and many have incomes between 20,000 and 70,000 marks. The shepherd above mentioned is said to be worth 3,000,000 marks (£150,000). Two quacks asked, and were paid, 10,000 marks (£500) for the treatment of a tuberculous knee-joint. A cook, suffering from incipient tuberculosis, had to pay 80 marks each visit for treatment by X rays; a woman suffering from cancer paid a quack 3080 marks, and, in addition, gave him her jewellery. A patient in humble circumstances who was visited by a quack at her own home had for each visit to pay 20 marks for the attendance, and from 7 to 10 marks for medicines, the total expenses being 475 marks at her death. Some patients had spent all their property for treatment by quacks, and some patients who were maintained by the Poor-law authorities and attended by the Poor-law medical officer, secretly consulted quacks and paid from 2 to 3 marks a visit out of the money distributed to them by the Poor-law officials. Certain quacks resort to the device of advertising gratuitous consultation, the result being that the patients do not pay for the "advice," but only for medicine, the latter having to be bought either from the quack himself or from some neighbouring druggist who is in league with him and charges from 20 to 25 marks for medicine worth not more than 5 marks, the difference being credited to the quack. One of this category intended to establish a special sanatorium for his patients when he was arrested for misdemeanour, and having been liberated on giving bail of 30,000 marks he forfeited his bail and made his escape to a foreign country. The majority of the quacks have no education; in Berlin, for instance, it was stated that only 24 per cent. of the men and 1 per cent. of the women had a college training. The list of quacks include all sorts and conditions of men, from clergymen to music-hall artists and from lawyers to carpenters. They usually declare that they have got their medical knowledge from books, but evidently the great majority of them are unable to understand what they may have read. Dr. Reissig gives some interesting samples of letters written by certain renowned quacks to show their low standard of education. Many of them are criminals who have served sentences, not for infringements of the existing laws and regulations concerning medical practice but partly for offences of a worse description. The list given by Dr. Reissig includes men convicted for burglary, for fraud, for extortion, for offences against morality, and for having caused death by negligence. In some cases these crimes were committed previously to, but in certain cases during, their medical practice. Sometimes the culprit resumed practice immediately after coming out of prison. The most remarkable case is that of a murderer who was sentenced to death in 1858, but whose sentence was commuted to confinement in a penitentiary. After a detention of 31 years he was liberated in 1889, when he began to practise medicine. A few years later he was prosecuted for having caused death by negligence in administering an overdose of morphine to a woman, but was acquitted by a jury. It is no wonder that attempts have been made by the representatives of the medical profession to amend the present state of the law, which allows any person whatever to practise medicine, provided that he is careful not to assume a title equivalent or similar to the special titles of duly qualified medical men. After many years of hesitation the Government at last gave a general approval to the proposals of the medical profession, and two years ago a Bill was introduced for the restriction of unqualified practice, but could not be discussed because of other urgent parliamentary business and the closing of the parliamentary session. The principal paragraphs of this Bill were described in THE LANCET of March 14th, 1908, p. 818. It may be remembered that they provided for a registration of unqualified practitioners; that these persons would have to keep books and inform the authorities as to their medical training; and that they would not be allowed either to treat patients by letter, or to attend venereal and infectious diseases, or to administer narcotic compounds. Unqualified persons who might be proved to have caused injury to the health of patients might also be debarred from practising, and the sale and the advertisement of patent medicines and remedies for venereal diseases were prohibited. This Bill is now re-introduced and the first reading is about to come on. The Bill is nearly the same as it was two years ago, some paragraphs excepted. A provision has been added to prohibit unqualified persons from mentioning their registration in their advertisements or on their door-plates. When the text of the former Bill was published the medical journals expressed the opinion that compulsory registration, instead of being a hindrance to unqualified persons, would rather raise them in the popular estimation, and that they would not fail to give the utmost publicity to their registration for the purpose of making their dupes believe that it was equivalent to a medical qualification. This is avoided by the above-mentioned clause. Another new clause specifies the diseases the treatment of which may only be undertaken by duly qualified medical men. In the former Bill the diseases were only the venereal and infectious diseases; the new Bill gives a detailed list of them, including cholera, small-pox, enteric fever, and cancer. A third new provision, which will certainly be very detrimental to quacks, is that they are to be forbidden to dispense medicine themselves or to give to their patients the address of a certain druggist or pharmaceutical chemist as the only vendor of the medicine prescribed. Two new provisions will be of special interest to foreign medical men; the one exempts foreign medical men from the prohibitions embodied in the law when they have been called to a consultation in Germany

[1] See THE LANCET, Dec. 3rd, p. 1650.

by a patient or a German medical man; the other empowers the Imperial Chancellor to dispense medical men holding foreign diplomas from the provisions of the law concerning the keeping of books and the treatment of certain diseases. Registration, however, is in every case compulsory for holders of foreign diplomas, and cannot be dispensed with by the Chancellor. The new Bill will certainly correct many of the abuses connected with quackery, and it may be accepted as satisfactory by the medical profession, especially since it is understood that the legislature is not at present disposed to take up the question of suppressing unqualified practice.

Twenty-eighth German Congress of Internal Medicine.

This Congress will take place next year from April 19th to 22nd at Wiesbaden, under the presidency of Professor Dr. Ludolf von Krehl of Heidelberg. The principal papers announced for the first day's proceedings are: Upon the Nature and Treatment of Diatheses, by Geh. Med. Rat. Professor Dr. Wilhelm His of Berlin, Professor Pfaundler of München, and Professor Bloch of Basel. Announcements of papers which it is intended to read must be sent, with a short abstract thereof, to the Secretary before March 22nd next. In connexion with the Congress there will be an exhibition of preparations, apparatus, and instruments so far as they relate to internal medicine. All applications must be made to the Secretary of the Congress, Geh. Sanitätsrat Dr. Emil Pfeiffer, Wiesbaden, Parkstrasse, 13.

Dec. 5th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Health Department of Toronto.

AFTER a service of 18 years, Dr. Charles Sheard has again tendered his resignation of the position of medical health officer of Toronto, and Dr. Charles J. C. Hastings (Toronto) has been appointed to succeed him. Dr. Hastings two or three years ago organised the Milk Commission of the Canadian Medical Association, and since then has been its chairman. In connexion with the clean milk campaign he has been a strong influence throughout Canada in promoting the formation of branch commissions. He believes that all milk not certified should be properly pasteurised. For the Toronto Laboratory Dr. Hastings advised the appointment of Mr. G. G. Nasmith, Ph.D., of the Ontario Board of Health, and the city has made the appointment. Dr. Hastings will endeavour to bring the health of Toronto to the highest standard.

Hypochlorite Treatment of Water.

Just before leaving the laboratory of the Ontario Board of Health to assume the position of chief of the Toronto laboratory, Dr. Nasmith had made some investigations as to the treatment of water by chloride of lime, which he found of undoubted value. A special circular has been issued by the Board which will be particularly valuable to hunters, prospectors, and campers. In this it is set out that one level teaspoonful of chloride of lime dissolved in three cupfuls of water, and one teaspoonful of this solution added to two gallons of water, will render it free from bacteria and leave the water good for drinking.

Sepsis in Medicine.

Dr. William Hunter of the London (England) Fever Hospital, who came out to deliver the opening address of the Medical Faculty of McGill University, Montreal, came on to Toronto and gave an address to the Academy of Medicine. Dr. Hunter emphasised the importance of sepsis to the physician as well as to the surgeon, and said that they should be antiseptic physicians as well as antiseptic surgeons. He discussed the part which decayed teeth and pus formation in the gums played in the causation of anæmia, especially in pernicious anæmia, putting forward the view that pernicious anæmia is really a chronic infection.

Radium in the Treatment of Cancer.

Dr. Louis Wickham of Paris has also paid a visit to Montreal and Toronto recently, at the latter place being the guest of Dr. W. H. B. Aikins. A special meeting of the Academy of Medicine was arranged, at which Dr. Wickham gave an illustrated lecture on the use of radium in the treatment of cancer and other diseases, and on the selective action of radium. The meeting was largely attended and several practitioners came some distance from outside points.

The Complete Physicians.

The above was the title of Professor J. George Adami's address at the opening lecture of the present session at the Medical Department of the University of Toronto. Professor Adami had a good deal to say in his address about Bulletin No. IV. of the Carnegie Foundation. While McGill and Toronto had been referred to repeatedly in this report, they are apparently considered of a lower class compared with some institutions in the United States, which demand that, before a four years' course in medicine, at least two years should be spent at a university or college. Professor Adami discussed this matter by proposing two questions:—1. Are a college course and an arts degree essential for the complete physician? 2. Is the Carnegie Report justified in making the entrance requirements of the school the standard whereby to classify the medical schools of this continent? He does not urge two or three years in arts and five in the medical course, as prolonged training tends to make a man become stale. Professor Adami believes in the fifth year, now pretty generally a requirement in Canada, which year spent in a hospital will produce magnificent training. He thought the Halifax school had been unjustly criticised in the report.

Mortality from Consumption Decreasing in Montreal.

It was announced at the annual meeting of the Royal Edward Institute that during the past 12 months in Montreal the mortality from pulmonary tuberculosis had decreased by 67. Montreal is said by the President of the Institute to be still 50 per cent. ahead of Boston, New York, and other American cities in consumption mortality. In 1907 the deaths in Montreal from all forms of tuberculosis were 953; in 1908, 945; and in 1909, 845. The corresponding deaths from pulmonary tuberculosis were 748, 760, and 685. To the institute 431 new cases were reported during the year, and 836 patients attended the dispensary. The total number of consultations was 6004, and the number of visits made by the inspector was 4716. The total number of patients on the list was 773, of whom 300 have died, 48 were lost sight of, and 425 still remain for treatment. Lieutenant-Colonel Burland was re-elected President of the Institute, and Dr. E. P. Lachapelle as first vice-president.

Infant Mortality in Ontario.

The Ontario Government has caused to be prepared and published a special report on infant mortality throughout the province. This report was prepared by Dr. Helen MacMurchy (Toronto), who states that infant mortality is the greatest problem of preventive medicine. In Ontario, according to the thirty-eighth annual report of the Registrar-General for 1907, the total number of deaths was 35,502, and the number of deaths under 5 years of age was 9930—that is, 29 per cent. of the total. Compare with this the total deaths due to tuberculosis in 1907—namely, 2530, or 8 per cent. of the total. Whilst not enough work is done about tuberculosis, what is said or done about infant mortality? In the city of Toronto in 1907 there were 1313 deaths under one year of age, and the total number of births was 6680. This gives an infant mortality of 196 per 1000. These figures emphasise the need for an educational campaign in the province, as nearly 10,000 die annually in Ontario under 5 years of age.

Health Conference at Ottawa.

There was held recently in Ottawa, under the auspices of the Public Health Department of the Canadian Conservation Commission, an important conference of Federal and Provincial health officials. Different committees were formed and these subsequently made recommendations to the conference. The Committee on Pollution of Waterways recommends a law prohibiting and penalising the deposition of raw sewage in the waterways of Canada, and towards this end it presented a draft Bill for each province to give effect to, so that there shall be no conflict of jurisdiction between the Dominion and Provincial Governments. Legislatures are to be asked to insert a clause in their various Health Acts that no sewerage or water-works construction can be undertaken by any municipality until the approval of the Provincial Board of Health has been obtained. The Federal Government is advised to confer with the United States with a view of preventing any further pollution of international waterways. The report of

the Committee on Tuberculosis recommends that the Dominion Government should be urged to give substantial assistance to encourage the establishment of new sanatoriums and hospitals for consumptives. It also recommends that areas of Crown lands should be secured early, to be set apart for colonies of the tuberculous and their families. It was decided to recommend to the Government that a permanent National Council of Health should be established under the Conservation Commission, and also that a national public health laboratory should be established to manufacture vaccines, toxins, and antitoxins, and analogous products, and also to supervise the manufacture, sale, and importation of such products. An officer of the Commission will shortly be sent to the United States to study and to report upon the work and expenses of such laboratories.

Toronto, Nov. 26th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Sanitation in Eastern Bengal and Assam.

PERHAPS one of the most interesting and instructive reports issued by the Government of Eastern Bengal and Assam for 1909 is that dealing with sanitation. There seems to be a connexion between the birth-rate of one year and the general healthiness of the year immediately preceding it. In 1907 the mortality was the lowest recorded since the formation of the province. In 1908 the birth-rate was the highest. The slight fall in the birth-rate during the year under review (which, however, was higher than any other province except the Central Provinces) corresponds with the slight rise of mortality in 1908. Last year there were but two cases of plague and these cases were imported into the Province. The absence of plague seems to be due to two facts: first, that the people do not live in houses where the mus rattus can find an easy home. The roofs are, especially in Dacca, flat thatched and sometimes corrugated. The rat is unable to live and breed as it does in houses with tiled roofs. The second reason is that Eastern Bengal and Assam possesses so many rivers which overflow their banks, and this from a sanitary point of view is of high importance. "Fevers" (a most inexact term) account for many deaths, the mortality ostensibly being highest in the cold weather months of November and December and lowest in February. It is interesting to note that in the three districts in which vaccination has made least headway (Rangpur, Bogra, and Dinajpur) small-pox was greatest. The epidemic was traceable to Calcutta. The results of the Malaria Conference at Simla should lead to far-reaching results in the young province. The main recommendation, it will be remembered, was that anti-malarial measures on any large scale should always be preceded by a systematic investigation of the distribution of the disease and by a critical examination of vital statistics. The local government has already set to work on these lines, and the results, especially in such malarious districts as Jalpaiguri and Dinajpur, are awaited with considerable interest. It is disappointing to note that the vital statistics are still in an unsatisfactory way. Nothing ought to be done to weaken the obligation of the householder to report. There should be more checking, and prosecutions ought to be instituted by the vaccinating staff, who should be rewarded for convictions obtained. Without reliable statistics reform must always be a leap in the dark.

Medical Work in the Punjab.

Colonel A. L. F. Bate's report on the dispensaries and charitable institutions of the Punjab for 1909 shows the salient feature to be not so much the excellent work of these institutions as the clear indications of the gradual and steady extension of medical relief, and of the growing confidence of the masses in the Western system of medicine. This last point is especially borne out by the figures for the total number of patients of all classes. During the year, which was a healthy one on the whole and free from outbreaks of epidemics, except plague, over 4,511,751 persons were treated, only slightly fewer than the phenomenally large number in the previous year when a severe epidemic of malaria ravaged the Province. Moreover, the number of women and children attending the dispensaries during the year showed a considerable increase over the figures for the previous year, a fact which alone demonstrates that the people are more ready to resort to these institutions in cases of illness than formerly. Special efforts are being made to recruit suitable lady doctors, and there are now five female assistant surgeons and 11 female hospital assistants working in the hospitals and dispensaries, which is a satisfactory advance. The Lieutenant-Governor, endorsing the remarks of the Inspector-General of Civil Hospitals, considers that it is necessary to provide for selected men of the hospital assistant class a better career than that now open to them. His honour refers in particular to the case of Hospital Assistant Mathra Das, whose surgical record is the second in the whole province. "It savours terribly of red tape," says the review, "that such an officer should not be able to rise in Government service to a salary exceeding Rs.70."

Lunatic Asylums in Burma.

Colonel W. G. King, C.I.E., I.M.S., just before his recent retirement published the annual note on the Burma lunatic asylums at Rangoon and Minbu. There is a marked increase of recent years in the number of lunatics in Burma, an increase of 70 per cent. in the past ten years. Lower Burma furnishes lunatics to the extent of 8·2 per 100,000, and Upper Burma 3·3—a statement which well illustrates the connexion between the development of a province and the resulting pressure on the mental powers of its inhabitants. The question of accommodation for lunatics is a pressing one; even the new temporary asylum at Minbu is full up and the Rangoon Asylum is constantly overcrowded. At Minbu the newly instituted small infiltration gallery for distributing good water has been a success, and Dr. H. E. Wells, the superintendent, considers it should serve as a model for the water-supply of the town of Minbu. The death-rate at Minbu was 32 per 1000, including three fatal cases of cholera, probably fly-borne. At Rangoon the death-rate was 93 per 1000. We learn that forcible nasal feeding was practised in 31 cases, in one case for 64 days, and in the others for an average of 16 days, with good results. It is very interesting to note that there were two fatal cases of general paralysis of the insane—a disease usually considered very rare in Indian asylums. Captain W. S. J. Shaw, I.M.S., the superintendent of the Rangoon Asylum, recently had two such cases also, so perhaps the disease is not quite so uncommon as supposed.

Malarial Fevers in Eastern Bengal and Assam.

It is regrettable, in view of the extensive prevalence of malaria which continues in Eastern Bengal and Assam, to find that a deep-rooted prejudice against the use of quinine still characterises that province. Except in the Faridpur district, which sold a considerable number of tablets, and where these appear to be generally preferred to quinine powders, and in Rangpur, where they seem to be gradually acquiring an increasing popularity, tablets have not apparently found any great favour with the people. The percentage of quinine distributed to the population of Eastern Bengal during 1909 is, however, nearly double that distributed in Assam, and a possible explanation of this fact is the extensive free distribution on tea-gardens by managers in the latter region. There can be no doubt, however, that the comparatively exiguous amount of quinine sold over the entire province does represent a very marked objection to the medicine, and that the prejudice indicated can only be removed by slow degrees, as its value as a prophylactic and a remedy for malarial fever becomes better known to the people. It must, therefore, be a great satisfaction that the memorandum issued not long ago by Dr. A. Bentley on quinine distribution has been receiving careful attention in Eastern Bengal and Assam, and that it has already been used as the basis of recommendations for radical changes, not only in the method of distribution, but also in the form of quinine chosen for use in the provinces. Briefly reviewed, the scheme which it is proposed to adopt consists in the abolition of the pice-packet system and the substitution for it of a system in which the minimum amount of quinine to be sold to a consumer is sufficient for the treatment of an attack of fever. To meet this requirement it is proposed to issue "treatments," consisting of 20 four-grain tablets of hydrochloride of quinine, this salt being adopted because of its higher quinine content

and much greater solubility as compared with the sulphate. Each "treatment" will be issued in a glass phial enclosed in a wrapper containing directions for use of the contents, and simple instructions for the personal prophylaxis of malaria. Ten treatments constitute a "parcel," the minimum quantity to be sold to retailers, and this will be so packed as to be capable of transmission through the post without risk of breakage. It is proposed to sell treatments at 3½ annas each, retailers getting a profit of 9 annas on the sale of a parcel. This profit, which amounts to about 33 per cent., has purposely been fixed at a high rate in order to encourage the sale of quinine, and with the same object it is proposed to make the retail agency as wide as possible and to resort to the use of advertisements, leaflets, and posters. A separate scheme is also under preparation for special "treatments" for children, consisting of tannate of quinine, or some other comparatively tasteless salt mixed with an attractive flavouring agent; while in order that the very poor may not be excluded from the benefits of the "treatment" system, it is further proposed to make provision for the free distribution of quinine by special agency in areas severely affected by malaria.

Malaria in Burma.

A resolution issued by the Government of Burma refers to the malaria conference at Simla in October last year and mentions that the conference particularly recognised the importance of conducting systematic investigations into the distribution of malaria, its epidemiology and endemiology, and the value of quinine and other remedies. To direct and coördinate such investigations the Government of India has announced its intention of appointing a central scientific committee and it has invited the Government of Burma to establish a provincial committee to work in consultation with the central committee and to carry out investigations in this province. The Lieutenant-Governor of Burma has accordingly appointed a provincial malaria committee which will be constituted as follows:—Inspector-General of Civil Hopitals, Burma, the Commissioner of Pegu Division, the Sanitary Commissioner of Burma, the Sanitary Engineer of Burma, the senior civil surgeon, Rangoon, Dr. A. R. J. Douglas, Dr. Harry Findlay, Mg. Atoon Myat, Dr. T. F. Pedley, Mg. Ba Shin, Mr. B. J. B. Stephens, the Hon. Mg. Be Too, Captain A. Whitmore, I.M.S., and the Deputy Sanitary Commissioner, Burma (secretary). The committee will hold its meetings in Rangoon and is empowered to obtain any information which it may require from officers of Government, who will, his honour is confident, coöperate with it by every means in their power. It is specially important that the committee should be fully informed about the local conditions and idiosyncrasies of the people in different parts of the province.

The Birth-rate in the Central Provinces.

The Central Provinces and Berar boast the highest provincial birth-rate in India. It was 51·63 per 1000 last year, and though this was lower than it had been for five years, it was still over 11 per 1000 more than the rate for Eastern Bengal and Assam, which comes second on the list for the whole country. Side by side with this high birth-rate, it is sad to notice, however, the direct effect it has on the mortality returns for the province. This will be understood when it is mentioned that one out of every two deaths which takes place is that of a child under the age of five years. The infantile mortality during 1909 was 221·94, and enormous though this appears, it still compares favourably with the rate for 1908. Reformation in domestic hygiene is of course what is required for lowering the infantile mortality, and this is a much more complex problem than that with which the Finance Ministers have been faced in finding grants for sanitation. No more progress has been made towards the solution of the problem in the Central Provinces and Berar than elsewhere in India. Efforts that have been made to train midwives have met with scanty success, but they are not to be abandoned, as the Chief Commissioner is optimistic and believes that some good may be done at last. Captain H. N. Stokes, I.M.S., the Sanitary Commissioner, advocates the employment of one really good woman at each headquarter town, whose methods would become known and from whom, by a system of apprentices, the want of experienced midwives may become satisfied.

Nov. 12th.

Obituary.

THOMAS NADAULD BRUSHFIELD, M.D. ST. AND., M.R.C.S. ENG., F.S.A.

Dr. Brushfield died on Nov. 28th at his residence, The Cliff, Budleigh Salterton, Devon, in his 82nd year. The deceased, who received his medical education at the London Hospital, qualified M.R.C.S. in 1850, and 12 years later graduated M.D. of St. Andrews. After holding a resident appointment at the London Hospital, Dr. Brushfield was appointed medical superintendent at the Chester County Asylum. He held this post for some years, and was then made medical superintendent of the Surrey County Asylum at Brookwood, retiring on a pension in 1882, mainly owing to the effects of an injury received from a patient. Afterwards he settled at Budleigh Salterton, where he soon became very popular. He took great interest in archæology, and was a frequent contributor to "Devon and Cornwall Notes," and his examination of old documents brought out many facts concerning the life of Sir Walter Raleigh (who, as Dr. Brushfield showed, really spelt his name Ralegh). Dr. Brushfield was much interested in all matters relating to Sir Walter Raleigh, and when the Canadian and American journalists visited Devonshire last year he gave them an interesting address on the subject, showing them over Hayes Barton, the interesting old house where Raleigh was born.

Dr. Brushfield also contributed to the English Dictionary published by the University of Oxford, to which he furnished no less than 70,000 references to local antiquarian and literary subjects. Among the more important of his works are a history of All Saints Church, East Budleigh, and the "Life and Writings of Sir Walter Ralegh." He was a member of the Medico-Psychological Association and of the British Archæological Association; honorary member of the Chester Medical Society, of the Torquay Natural History Society, of the Teign Naturalists' Field Club, and of the Chester Archæological Society; local secretary and Fellow of the Society of Antiquaries, and member and past president of the Devonshire Association (1893). The pages of the "Western Antiquary" and the volumes of the Transactions of the Devonshire Association for the past 28 years owe much to his pen. Dr. Brushfield possessed one of the most valuable and extensive libraries in the West of England. He will be much missed in Budleigh Salterton and the district.

EDWARD HENRY BRIEN, M.D. DUB.

REGRET is expressed in Rock Ferry and district at the death of Dr. Edward H. Brien, which occurred with painful suddenness on Nov. 24th. Dr. Brien commenced practice in Rock Ferry 22 years ago in succession to the late Dr. Nixon, and was only 52 years of age at the time of his death.

Dr. Brien's father, a fleet-surgeon in the navy, who served in the Crimean war, died whilst his son was yet a boy, and an uncle, Archdeacon Brien, acted in consequence in place of a parent. From school Edward Brien went to Trinity College, Dublin, and there graduated as B.A., and later took his M.D. degree. He was only 30 years of age when he settled in Rock Ferry, but from the first he was a general favourite with all classes. He became a keen politician and an energetic public man. He served for many years on the Birkenhead town council, acting on many committees, and he gave excellent service as chairman of the electricity committee, for which position he was well fitted by his practical knowledge of mechanics. Later he was elected to the position of chairman of the watch committee, and he had just been reappointed to this post at the time of his death. He was a keen motorist and understood his car better than any other medical man in the town. He was, in fact, the pioneer of motoring in the district, his steam-car being the first of its kind and also the first doctor's motor in Birkenhead. He was president of the Birkenhead Medical Society in 1904, and was a constant and active member up to the end. He was also chairman of the Conservative party in his district, and in all branches of his work he was universally popular.

He apparently enjoyed robust health until a short time ago, when he occasionally complained of pains in the neck and left shoulder, which he attributed to rheumatism, and it was only on Nov. 16th, whilst doing his morning round

that a severe attack caused him to realise that he was the victim of angina pectoris, and attention being drawn to the urine he was found also to have glycosuria. On the morning of his death he expressed himself as well and fit for work, and indeed the fatal seizure was probably induced by his running upstairs for his visiting list, for he dropped in the room and died almost immediately with the book in his hand.

The funeral was a very representative one, the Mayor, many members of the town council, corporation officials, fire brigade, police, and a large portion of his professional brethren turning out to do the last honour to one who had been adviser, colleague, and friend to so many, who had served his community so well, and stood so high in the esteem of the poor. Much sympathy is felt for his wife and two sons, the elder of whom is studying for his father's profession.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. W. Forest, professor of orthopædic surgery in Pennsylvania University, Philadelphia.—Dr. Hans Goldschmidt of Berlin, an eminent urologist, who devised a valuable form of urethroscope. He was 58 years of age.

Medical News.

UNIVERSITY OF OXFORD.—In the recent examination for the Diploma in Public Health the following were approved:—

Part I.—H. S. Burnell-Jones, D. G. Evans, F. R. Seymour, and C. B. Roscrow.
Parts I. and II.—P. N. Cave, T. Chetwood, R. A. Clapham, W. P. MacArthur, A. C. Parsons, O. P. Turner, and G. C. Welch.
Part II.—G. Finch and Rachel E. W. Mackenzie.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates have passed the primary part of the Fellowship Examination:—

Mr. J. D. Cherry, Miss Z. A. De Cruz, L.R.C.P. & S. Edin., Mr. T. O. Graham, M.B., B.Ch. Dub., Mr. J. R. May, Mr. G. E. Pepper, and Mr. S. R. Rao, L.R.C.P. & S. Edin.

The following candidates have passed the final part of the examinations and have been admitted Fellows of the College:—

Miss I. M. Clarke, L.R.C.P. & S. Irel.; Mr. H. English, M.B., B.Ch. Dub.; Mr. K. T. Nath, L.R.C.P. & S. Edin.; Mr. G. F. Shepherd, L.R.C.P. & S. Irel.; and Miss C. F. Williamson, L.R.C.P. & S. Irel.

UNIVERSITY OF BRISTOL: THE LATE DR. LONG FOX.—The seventh annual "Long Fox" lecture will be delivered in the medical library on Dec. 15th at 4.15 P.M. by Professor J. Michell Clarke. The subject will be "Cerebro-spinal Syphilis."

ROYAL INSTITUTION.—The following are the lecture arrangements at the Royal Institution before Easter:—Professor Silvanus P. Thompson: A Christmas Course of Six Illustrated Lectures on Sound, Musical and Non-musical, a Course of Experimental Acoustics, adapted to a Juvenile Auditory—(1) production of sound; (2) transmission of sound; (3) reception of sound; (4) combination of sounds; (5) registration of sounds; and (6) reproduction of sound. Dr. F. W. Mott, Fullerian professor of physiology, R.I.: Six Lectures on Heredity. Dr. A. E. H. Tutton: Three Lectures on Crystalline Structure—mineral, chemical, and liquid. Dr. M. Aurel Stein: Three Lectures on Explorations of Desert Sites in Central Asia. The Astronomer Royal, Mr. F. W. Dyson: Three Lectures on Recent Progress in Astronomy. Dr. P. Chalmers Mitchell: Three Lectures on Problems of Animals in Captivity. Mr. A. C. Benson: Two Lectures on Ruskin. Dr. Arthur Keith: Two Lectures on Giants and Pygmies. Professor W. A. Bone: Two Lectures on Surface Combustion and its Industrial Applications. Professor Sir J. J. Thomson, professor of natural philosophy, R.I.: Six Lectures on Radiant Energy and Matter. The Friday evening meetings will commence on Jan. 20th, when Professor Sir James Dewar will deliver a Discourse on Chemical Change at Low Temperatures. Succeeding discourses will probably be given by Professor W. H. Bragg, Mr. A. E. Shipley, Professor H. E. Armstrong, Professor Jean Perrin, Professor Karl Pearson, Mr. J. H. Balfour-Browne, Sir David Gill, Professor H. S. Hele-Shaw, Professor Sir J. J. Thomson, and other gentlemen.

A GLOUCESTERSHIRE CENTENARIAN.—Mr. T. M. Enstone of Sandhurst, Gloucestershire, died on Nov. 24th. There is an official record of the fact that he was christened on Oct. 9th, 1808.

Messrs. Down Bros., Limited, of St. Thomas's-street, London, have been awarded the Grand Prix (highest award) for surgical instruments and aseptic hospital furniture at the Buenos Aires Exhibition, 1910, as well as the Grand Prix (highest award) at the Brussels Exhibition, 1910.

THE LATE DR. ARTHUR FOXWELL.—At the Queen's Hospital, Birmingham, the Foxwell Memorial Tablet was unveiled by Professor Jordan Lloyd on Nov. 22nd, in the presence of a representative company of the subscribers, hospital staff, committee, residents, and nurses. Professor J. T. J. Morrison, chairman of the medical committee, presided, and Mrs. Foxwell and Miss Foxwell were amongst those present. The tablet, which is of bronze, is in the form of a memorial bust, and is the work of Mr. Courtenay Pollock. It is inscribed: "Arthur Foxwell, physician to this hospital, 1889–1909. Erected by his colleagues and friends." Professor Morrison said the proceedings that afternoon were the outcome of a movement begun some months ago by the medical committee. They felt strongly and unanimously that the hospital ought to contain some conspicuous evidence of the regard and affection in which they held their late friend and colleague. It was not forgotten that the open-air ward in the medical building—the first of its kind, as far as he knew, in England—must always be associated with him. The idea was his sole conception and was carried into effect under his thoughtful supervision. But they wanted something more obviously personal and distinctive upon which his name might be inscribed, and which would challenge the notice and inquiry of the observer. After due consideration it was decided—and he felt sure the subscribers would endorse the decision—that the memorial should take the two-fold form of a mural tablet and a medical prize. The tablet was very appropriately the work of Mr. Courtenay Pollock, a stepson of Dr. Foxwell, and an artist of considerable talent. The endowment fund of the Foxwell Memorial Essay would provide a prize in clinical medicine, to be competed for annually by qualified residents of the Queen's Hospital, General Hospital, and the Children's Hospital. By these means they wished, and they expected, to preserve the memory of their friend in the minds of his fellow workers, and to continue the influence of his personality upon those who might follow them in the future. Professor Jordan Lloyd, as the senior member of the Queen's Hospital staff, then unveiled the tablet. He referred with emotion to his long friendship with Dr. Foxwell, and said he had learned to hold him in the highest regard as a man, to esteem him as a scholar, and to revere him as a devotee of the profession he had chosen. Invited to speak by the chairman, Dr. O. J. Kauffmann, the senior physician, said that it might interest those present to learn what had been done with the money collected for the Foxwell Memorial. The sum subscribed was close upon £200. £50 had been paid for the memorial tablet, and the rest had been invested in a debenture security, which would bring in about £6 per year. This small amount it was proposed to present annually for the best prize essay, which should be open to competition by the residents of the Queen's, the General, and the Children's hospitals. The subject of the essay would be fixed by the medical committee of the Queen's Hospital, which had reserved to itself the right to alter the regulations affecting the prize if it should appear that a change would be advantageous. They had thought it well to depart from the usual fashion of giving a prize to students because they knew that the plan they had devised would have been approved by Dr. Foxwell, whose sympathy was ever with young members of the profession who endeavoured to further the march of science; and they trusted that those who would compete for the prize would use personal observations on disease as the mainstay of their essays. Mr. Keep, chairman of the hospital committee, in moving a vote of thanks to the chairman and to Professor Jordan Lloyd, said the memorial would serve as a link between these days and the days to come. It would remind the men and women

who were in the hospital of a distinguished man who had preceded them, and whose memory his friends delighted to honour. The motion was seconded by Alderman Clayton, and was duly carried and acknowledged.

METROPOLITAN WATER BOARD: APPOINTMENT OF DISTRICT MEDICAL OFFICERS.—The Works and Stores Committee of the Metropolitan Water Board reported, at the meeting of the Board on Friday, Dec. 2nd, vacancies caused by the resignation of Dr. Percy Pope and the death of Dr. C. Adams, district medical officers for the Barrow Hill Division of the Western District and the Buckhurst Hill Division of the Eastern District respectively. To fill these vacancies it was resolved to appoint Mr. Beresford Kingsford, M.D., D.P.H., in the Western District, and Mr. P. W. Moore, M.B., M.R.C.S., L.R.C.P., in the Eastern District. The committee had also received notice of the resignation of Dr. T. E. B. Meyler, of the Battersea, Brixton, and Wandsworth Division of the Southern District, and a report as to filling the vacancy was promised at a later date. Dr. W. Anderson, who was appointed to act jointly with his partner, Dr. R. Cobb, in the East of Lee Division of the Eastern District, has removed from the neighbourhood, but the committee considered it unnecessary to fill the vacancy thus caused, and his name was removed from the Board's list of district medical officers.

A SPECIAL meeting of the medical men resident in the electoral division of Rossendale was held on Nov. 30th at Rawtenstall. There was a good attendance. Dr. J. Brown of Bacup was called to the chair, and Dr. E. W. Falconer of Stacksteads was asked to act as secretary. The Chairman stated that the meeting was convened to discuss the questions of State sickness and invalidity insurance, and of coroners' law and death certification, as affecting the medical profession. Several members who had had experience in other parts of the country of club and contract practice spoke of its being most unsatisfactory. The following resolution was then proposed by Dr. J. Broomhead of Haslingden, and seconded by Dr. A. A. Edward of Rawtenstall:—

That the principle of limited payment for unlimited medical services has to a large extent proved most unsatisfactory to the patients and to the doctors. This meeting therefore is strongly opposed to this principle, and urges on the Government in any future legislation in the proposed State Sickness and Invalidity Insurance Bill that there shall be freedom of choice of doctor by the patient, and that the principle of payment shall be for medical services rendered.

This was carried unanimously. Copies of this resolution were ordered to be sent to the Right Honourable Lewis Harcourt, the Right Honourable Lloyd George, and the Central Council of the British Medical Association. Mr. McIlraith of Rawtenstall then proposed and Dr. J. A. Harrison of Haslingden seconded:—

That the proposed Coroners' Law and Death Certification Bill should be amended as follows: "That the body be viewed within three days of death having taken place, and that there be a minimum fee and mileage for the certificate."

This was also carried unanimously. The resolution was ordered to be sent to the Right Honourable Lewis Harcourt, Sir W. Collins, and the Central Council of the British Medical Association.

PRESENTATION TO MR. CHARLES J. BOND.—A representative assembly of members of the profession was present on Dec. 1st at the Grand Hotel, Leicester, when a presentation of a silver tea and coffee service was made to Mr. C. J. Bond. The proceedings commenced with an informal dinner to which nearly 90 gentlemen accepted invitations, though owing to the exceedingly inclement condition of the weather several were prevented from attending. The chair was occupied by Mr. C. F. Bryan, the oldest practising member of the profession in the town. At the close of the dinner the chairman gave the toast of "The King," and then briefly proposed Mr. Bond's health, reserving further remarks for the subsequent presentation ceremony. Mr. Bond made a short reply. The party then adjourned and a reception was held in an adjoining room, which was attended by a large number of the wives and daughters of the subscribers. The company was received by Mr. and Mrs. Bryan and by Mr., Mrs., and Miss Bond. The Mayoress of Leicester, Miss Vincent, was present. Mr. Bryan made the presentation. In felicitous terms he spoke of Mr. Bond's career at University College, where he carried off many prizes and held the appointments of house surgeon and assistant demonstrator of anatomy. After being house surgeon at Bedford Infirmary and Leicester Infirmary he joined the staff of the latter institution in 1886 and was now its senior surgeon. The chairman went on to speak of the high position which Mr. Bond held among the medical profession in Leicester and Leicestershire. He counted almost every medical practitioner as a personal friend, and many of them, their wives and families, as patients. Almost every medical practitioner in the district had contributed towards the presentation, and Mr. Bryan stated that it gave him the sincerest gratification to present the articles of plate to Mr. Bond. These consisted of a massive silver tea and coffee service and salver, on the last of which was inscribed: "To C. J. Bond, F.R.C.S., from his medical friends in Leicester and neighbourhood as a token of affection and esteem on his retirement from practice, 1910." Mr. Bond, in acknowledgment, wished all to understand that he felt very deeply the kindness of every one of the subscribers.

THE LONDON COUNTY COUNCIL AND THE TREATMENT OF SCHOOL CHILDREN.—The Education Committee of the London County Council are recommending that the agreements entered into by the Council with six metropolitan hospitals for the medical treatment of children in the Council's schools should be renewed for one year.

The Professional Pocket-book or Daily and Hourly Engagement Diary for 1911. Specially adapted for Professional Engagements. In three parts. January-April, May-August, September-December. Price not stated.

WRIGHT, JOHN, AND SONS, LIMITED, Bristol. SIMPKIN, MARSHALL, HAMILTON, KENT, AND CO., LIMITED, London.

Wrights' Improved Physicians' and Surgeons' and Consultants' Visiting List. Compiled by Robert Simpson, L.R.C.P., L.R.C.S. Form A. 1911. Eighteenth edition. Price from 5s. to 7s. each, according to size.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BOND, HOPETOUN R., M.D., C.M., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., has been appointed House Surgeon to the Teignmouth Hospital.

BOOTH-JONES, C., has been appointed Second Assistant Medical Officer to the Warwick County Lunatic Asylum.

BROWN, HORACE G., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Workhouse, District Medical Officer, and Public Vaccinator to the Bedwellty Board of Guardians *pro tem.*

BUZZARD, E. FARQUHAR, M.D. Oxon., F.R.C.P. Lond., has been appointed Physician to Out-patients at St. Thomas's Hospital.

CHOYCE, CHARLES COLEY, M.D. Edin., B.Sc., F.R.C.S. Eng., has been appointed Surgeon to Out-patients at the Great Northern Central Hospital.

DARLING, H., M.B., B.S., has been appointed House Surgeon at University College Hospital.

FISHER, F. R., F.R.C.S. Eng., has been appointed Honorary Consulting Surgeon to the Surgical Aid Society.

HUGHES, DAVID ARTHUR, L.R.C.P. Lond., M.R.C.S., D.P.H. Lond., has been appointed Medical Officer of Health of the County of Carmarthen.

JONES, EDWARD T., M.R.C.S. Eng., has been appointed Medical Officer and Public Vaccinator of the Petersfield Union, No. 1 East Meon District.

LEECH, H. B., M.D. Dub., has been appointed Senior Assistant Medical Officer to the Warwick County Lunatic Asylum.

O'DRISCOLL, P. L., M.B., B.S. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Timoleague District of the county of Cork.

OLLERENSHAW, ROBERT, M.D., Ch.B. Vict., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed an Honorary Assistant Surgeon to the Salford Royal Hospital.

ORR, JAMES, L.R.C.P. Edin., D.P.H., has been appointed Medical Officer of Health for the County Borough of Barrow-in-Furness.

SIMSON, H. J. F., M.B., M.S. Edin., F.R.C.S. Edin., has been appointed Assistant Physician for Diseases of Women at the West London Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSTAPLE, NORTH DEVON INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

BEDFORD COUNTY HOSPITAL.—House Physician. Salary £80 per annum, with apartments, board, and laundry.

BERMONDSEY INFIRMARY, Lower-road, Rotherhithe, S.E. — Second Assistant Medical Officer. Salary £120 per annum, with rations, washing, apartments, &c.

BOURNEMOUTH, ROYAL VICTORIA HOSPITAL.—House Surgeon. Salary £100 per annum, with board, rooms, and laundry.

BRADFORD UNION, EASTBY SANATORIUM, near Skipton.—Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with rations, apartments, and laundry.

BRIDGWATER HOSPITAL.—House Surgeon for six months, unmarried. Salary at rate of £100 per annum, with board, lodging, and washing.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with apartments, board, and laundry.

CAIRO, EGYPT.—Medical Tutor at School of Medicine and Registrar to Kasr-El-Ainy Hospital. Salary £E.600 a year.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Physician, unmarried. Salary £70 per annum, with board, lodging, and washing.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—Two House Surgeons for six months. Salary £30, with board, residence, and laundry.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Clinical Assistant.

DERBYSHIRE ROYAL INFIRMARY.—House Physician and Second House Surgeon for 12 months. Salary in each case £100 per annum, with apartments, board, &c. Also Assistant House Surgeon for six months. Salary at rate of £60 per annum, with apartments, board, &c.

GLASGOW PARISH COUNCIL, STOBHILL GENERAL HOSPITAL, Springburn.—Two Junior Resident Assistants (male and female). Salary £120 per annum, with board and apartments.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

INDIAN MEDICAL SERVICE, India Office, London.—Fourteen Commissions in His Majesty's Indian Medical Service.

LEEDS GENERAL INFIRMARY.—Ophthalmic House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and washing.

LEICESTER INFIRMARY.—Second House Surgeon for six months. Salary at rate of £100 per annum, with board, apartments, and washing. Also Honorary Pathologist.

LINCOLN GENERAL DISPENSARY.—Resident Junior Medical Officer, unmarried. Salary £175 per annum, with apartments, &c.

LIVERPOOL, HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Mount Pleasant.—Assistant Medical Officer and Pathologist. Salary £200 per annum.

MANCHESTER DENTAL HOSPITAL.—Honorary Anæsthetist.

MIDDLESEX HOSPITAL, W.—Second Assistant to Bacteriological and Clinical Laboratories.

NATIONAL DENTAL HOSPITAL AND COLLEGE, Great Portland-street, W.—Anæsthetist.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Assistant House Surgeon for six months. Salary £20, with board, lodging, and washing.

PARK HOSPITAL FOR CHILDREN, Hither Green, S.E.—Senior Assistant Medical Officer. Salary £250 per annum. Also Assistant Medical Officer. Salary £150 per annum. Both with board, lodging, and washing.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

ROTHERHAM HOSPITAL.—Senior House Surgeon. Salary £110 per annum, with board, lodging, and washing.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Assistant Physician.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—Tutor in Public Health.

ST. LUKE'S HOSPITAL FOR MENTAL DISEASES, Old-street, London, E.C.—Second Assistant Medical Officer, unmarried. Salary £130 per annum, with board, apartments, and washing.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, London, E.C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ST. THOMAS'S HOSPITAL.—Dental Surgeon.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SOUTHAMPTON, FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary £100 per annum, with rooms, board, and washing.

SOUTH UIST.—Medical Officer. Salary £100, with house.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician for six months. Salary £40, with board, lodging, and laundry.

WANDSWORTH UNION INFIRMARY, St. John's-hill, near Clapham Junction.—Junior Assistant Medical Officer, unmarried. Salary at rate of £120 per annum, with board, lodging, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Assistant Physician. Also Honorary Medical Registrar.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Athlone, in the county of West Meath; at Whitstable, in the county of Kent; and at Brigg, in the county of Lincoln.

Births, Marriages, and Deaths.

BIRTHS.

BUZZARD.—On Dec. 1st, at Wimpole-street, W., the wife of E. Farquhar Buzzard, M.D. Oxon., F.R.C.P., of a daughter.

DRAKE.—On Nov. 29th, the wife of A. W. Courtney Drake, M.B., B.C., of a son.

GUTCH.—On Dec. 1st, at Fonnereau-road, Ipswich, the wife of John Gutch, M.D. Cantab., of a son.

SODEN.—On Nov. 28th, at Mapesbury-road, Brondesbury, the wife of Dr. Wilfred Soden, prematurely, of a son (stillborn).

MARRIAGES.

BUSHNELL—EWING.—On Nov. 26th, at St. George's, Hanover-square, Percy Charles Bushnell, M.R.C.S., L.R.C.P., to Mary Jessie Ramsay, daughter of the late William Ewing, of Ardmohr, Kirn, N.B.

DEATHS.

BOND.—On Nov. 30th, at Suffolk Lodge, Maida Vale, Joseph Henry Bond, L.R.C.P.I., aged 54 years.

DE JERSEY.—On Dec. 2nd, at Ascot, Walter Brock de Jersey, M.B. Camb., of Netherton, Guildford, aged 47 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

RATS.

RATS are rapidly becoming creatures of first importance in sociology, and it is interesting to refer to chronicles and see how our fathers and grandfathers viewed the rat in its relation to mankind and civilisation. An article was published in the *Quarterly Review* in 1857 by Dr. Andrew Wynter, who wrote many essays on interesting subjects outside medicine and was also a medical journalist and editor of the *British Medical Journal* from 1856 to 1860. After quoting Grainger's poetic invocation, "Now, Muse, let's sing of rats," the "whisker'd vermin race," Dr. Wynter discusses the origin of the land rats in England, the old English black rat, and the Norwegian, or brown rat. The genuine ship rat, he states, is a more delicate animal than the brown rat, and the water rat he finds to be an entirely different species from the ship rat. Dr. Wynter's story of the extinction of rats from the London sewers is gruesome. Not many years since, he says, they existed in millions in the drains and sewers of the metropolis, but the method of flushing the sewers which had been adopted about the time of writing this article proved, he considered, exceedingly fatal to them. "When the sluices are opened," he says, "go they must with the rush of waters, and they may be seen shot out by hundreds from the mouths of the culverts in the Thames." The fact that rats in that hyper-sporting time were worth 3*s.* a dozen for sporting purposes proved, he thought, another most certain means of their destruction, for it ensured their ceaseless pursuit by man. Talking of London, he writes that the underground city of sewers became one vast hunting-ground, in which men regularly gained a livelihood by capturing them. These vermin congregated thickest in the neighbourhood of slaughter-houses or, in other words, where food was most plentiful. A remarkable tale is related of a great killing of rats by the proprietor of one of the Montfaucon slaughter-houses, who, aided by his workmen, killed 16,050 rats in a month, and 2650 in a single night on his own premises by means of blows from sticks held in one hand and torches in the other. Dr. Wynter gets off on his audience some well-known though little authenticated anecdotes of the sagacity of rats. He describes them as leading their blind companions to food, as fishing for oil with their tails, and as transporting eggs by the process of one rat lying on his back clasping the egg while his comrade drags him away by the tail. He speaks of the proprietors of the bonded wheat warehouses on the banks of the Thames who are forced to take the utmost precautions against the entrance of myriads of rats from the sewers and waterside premises, and describes wheat stacks and ricks in the country which, although seeming fair on the outside, are being really "little better than a huge rat-pie." Terriers and ferrets in their relation to rats receive a few pages of attention, and a tale is told of the driver of a London omnibus who made a pet of a piebald rat who acted as guardian of the driver's dinner on the boot of the omnibus and at night went home in his master's pocket, and on cold nights crept in his master's bed for warmth and slumber. At the word of command, "Come along, Ikey," he would jump into the ample great-coat pocket. The following paragraph must conclude our extracts from Dr. Wynter's interesting article:—

> "The rat, as we have said, has many enemies; the weazel, the pole-cat, the otter, the dog, the cat, and the snake hunt him remorselessly all over the world. Man, however, is his most relentless and destructive enemy. In some places he is killed for food, as in China, where dried split rats are sold as a dainty. The *chiffonniers* of Paris feed on them without reluctance. Nor is rat-pie altogether obsolete in our own country. The gipsies continue to eat such as are caught in stacks and barns, and a distinguished surgeon of our time frequently had them served up at his table. They feed chiefly upon grain; and it is merely the repulsive idea which attaches to this animal under every form that causes it to be rejected by the same man who esteems the lobster, the crab, and the shrimp a delicacy, although he knows that they are the scavengers of the sea. They were not always so nice in the navy. An old captain in Her Majesty's service informs us that on one occasion, when returning from India, the vessel was infested with rats, which made great ravages among the biscuit. Jack, to compensate for his lost provisions, had all the spoilers he could killed, put into pies, and considered them an extraordinary delicacy."

COMPLETE TRAUMATIC AVULSION OF THE HEART.

THE following case is worth recording. A boy, aged 6, was brought in dead to St. Mary's Hospital on Oct. 23th, death having been produced by severe injuries inflicted by a motor omnibus. The external injuries were strikingly slight, consisting merely of bruises and abrasions of both groins, the perineum, anterior part of left iliac crest, left clavicle, front of left and back of right elbow; the prepuce was also lacerated; a little blood was present on the face from the nose. On opening the body the following injuries were discovered: A depressed fracture of the symphysis, pubis, and left innominate bone; lacerated wounds of the anterior part of the liver, spleen, and small intestine. All the ribs on the left side, except the eleventh and twelfth, were fractured, mostly in two places, before and behind; on the right side the second rib was broken. The right bronchus was severed and the pedicle of the lung nearly divided; the lungs themselves were uninjured. The right pleural cavity was occupied by blood. The heart was completely detached, lying quite free therein at the lower part of the cavity. The pericardium had been ruptured on the right side vertically, and through this aperture the heart had evidently escaped. There was a fracture of the spine at the level of the third dorsal vertebra, as though produced by over-extension; rupture of the upper end of the descending aorta and rupture also of the œsophagus. There was a longitudinal fissured fracture of the posterior fossa of the skull, and slight capillary extravasation over the brain. Amongst other things, two features of special interest about this case were the absence of marks of external violence over the region of the thorax externally, and the condition and position of the heart, which was completely isolated from all its attachments, lying quite free in a pool of blood at the base of the right pleural cavity.

"A SEQUEL TO SECRET REMEDIES."

WE have received from Mr. Frederick Phillips a pamphlet with this title, which has been written in reply to the statements and inferences of "Secret Remedies" published last year by the British Medical Association.

BONE-SETTING.

WE received from Mr. H. A. Barker a letter on Nov. 23rd in reply to our article in THE LANCET under this heading. Mr. Barker says:—

> "You throw out a hint of doubt as to the authenticity of the facts given in Mr. Stead's article, and suspect that he has exaggerated the situation. It is an easy matter to verify the facts. You find it impossible to believe that I can have treated over 30,000 cases in under 20 years practice—*conjecturing* that I must take an "hour over each case," and stating that I said 5 to 20 manipulations were necessary for each patient. As a matter of fact, I wrote, in explaining my modus operandi for talipes valgus, that from five to twenty manipulations were sufficient to bring about a normal condition of things in the majority of cases *of this kind*. I did not say that such a number of visits was necessary for every case. As a matter of fact hundreds of my patients are finished with in 1 or 2 visits. I have frequently dealt with 4 and even 5 patients in an hour as my books will show. I have often had 35 and 40 patients through my hands in a single day, and on rare occasions 40 and 45. Taking only 5 patients a day, you will arrive at about the figures I have given you—without sunday—on which day I sometimes see a dozen or more cases."

We are happy to insert Mr. Barker's statement. Our impression was derived from Mr. Stead's article.

REMEDIA "HOECHST."

THE attention of our readers may with advantage be drawn to an excellent compilation by Messrs. Meister, Lucius, and Brüning, Hoechst-on-Maine and 51, St. Mary Axe, London, of the new remedies which chemical, pharmacological, and biological researches have placed at the disposal of medical science during recent years. The work is in German and deals very comprehensively with pharmaceutical products and serotherapeutic and bacterial preparations. In addition to a description of each preparation, chemical reports by well-recognised authorities are appended. Remedia "Hoechst" is a book of 794 pages, and should be a valuable work of reference to the practitioner who can read German. We understand that copies are supplied to the profession free of charge.

F. S.—In the present state of the law we fear nothing can be done to stop the appalling harm done by the advertising quack.

ERRATUM.—In Mr. Robert Jones's paper on Fractures in the Neighbourhood of Joints, which was published in THE LANCET of Nov. 19th, it is stated more than once that fracture of the neck of the femur is treated by Mr. Jones "in an adducted position." This should be "in an *ab*ducted position."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

„ 19th–22nd (Rome).—Twentieth Congress of Internal Medicine.

In 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
„ 23rd (Paris).—First Congress of French Medical Journalists.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
„ 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.

April 19th-22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
May-October (Dresden).—International Hygiene Exhibition.
May-October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May-October (?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
June 5th-8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th-29th (Belfast).—Congress of the Royal Sanitary Institute.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
" (Turin).—International Congress of Pathology.
Sept. 11th-15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).
" 11th-16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 18th-23rd (Sydney).—Australasian Medical Congress.
" 24th-30th (Rome).—International Congress on Tuberculosis.
" 25th-29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st-4th (Liége).—Second Congress of Alimentation.
Dec. 4th-9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Genoa).—International Exhibition of Marine Hygiene.

In 1912:—
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
" Visit of German Medical Men to America.
Nov. 22nd-29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—
(London).—Seventeenth International Congress of Medicine.
(Dresden (?)).—International Conference on Cancer.

In 1915:—
(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Jonathan Hutchinson, L. A. Dunn): at 5.30 P.M.

Papers:
Mr. W. G. Spencer: Septicæmia Hæmorrhagica; Severe Capillary and Parenchymatous Hæmorrhage of Septic Origin.
Mr. J. Hutchinson: Gastric and Intestinal Hæmorrhages (probably of Septic Origin) following Abdominal Operations.
Mr. A. E. Johnson: Fractures of the Patella without Separation of the Fragments.

WEDNESDAY.

SECTION OF BALNEOLOGY AND CLIMATOLOGY (Hon. Secretary—F. A. de T. Mouillot): at 5.30 P.M.

Paper:
Dr. Neville Wood: English Health Resorts for Foreign Invalids.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—H. G. Adamson, J. H. Sequeira), at 11, Chandos-street, W.: at 5 P.M.

Cases.

NEUROLOGICAL SECTION (Hon. Secretaries—E. Farquhar Buzzard, Wilfred Harris), at 11, Chandos-street, W.: at 8 P.M.

Clinical Meeting.

FRIDAY.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton): at 8.30 P.M.

Paper:
Dr. Horace Manders: The Use and Value of Electricity in the Treatment of some Abdominal Diseases.

Cases:
Dr. Lewis Jones: (1) Case of Gonorrhœal Arthritis of Wrist: (2) Case of Sprengel's Deformity; (3) Early Dupuytren's Contraction.

Unusual Cases, Skiagrams, &c., will also be shown by Dr. Ironside Bruce, Dr. Reginald Morton, Dr. A. D. Reid, and Mr. Gilbert Scott.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Dr. D. Ferrier: Acromegaly.—Prof. A. Keith: Acromegaly from an Anatomist's Point of View.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.

TUESDAY.—8 P.M., Mr. C. A. Hill: Note on the Crystallisation of Sodium Salicylate Solution (with demonstration).—Mr. J. C. Umney: A Triangular Contest in Peppermint Oils. Additions to the Museum:—Mr. E. M. Holmes: (1) Note on the Sleeping Sickness Fly and Tsetse Fly (with lantern Illustrations); (2) Note on Truxillo Coca,

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

WEDNESDAY.—5 P.M., Lieut.-Colonel M. W. Russell, R.A.M.C.: Divisional Collecting Stations for Wounded.—Major W. E. Miles, R.A.M.C.(T.): Pruritus Ani.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Adjourned Discussion on Sir Rubert Boyce's paper on Yellow Fever in West Africa. The following papers will also be brought up for Discussion:—Dr. S. T. Darling: Autochthonous Oriental Sore in Panama.—Dr. R. F. Jones: Tropical Diseases in British New Guinea.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. M. H. MacLeod: Clinique (Skin). 5.15 P.M., Lecture:—Dr. W. Ewart: The Therapeutics of Bleeding.
TUESDAY.—4 P.M., Dr. G. A. Sutherland: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. Collier: Some Forms of Peripheral Neuritis.
WEDNESDAY.—4 P.M., Mr. G. E. Waugh: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. W. S. A. Griffith: The Use of the Douche.
THURSDAY.—4 P.M., Mr. H. J. Paterson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. Blumfeld: Anæsthetics in Cases of Cardiac and Pulmonary Diseases.
FRIDAY.—4 P.M., Dr. StClair Thomson: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Armour: Intestinal Obstruction.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Armour: Intestinal Obstruction.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Mr. Ll. Williams: The Etiology, Prophylactics, and Treatment of Dental Caries.
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.
FRIDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Medical Registrar: Examination of the Abdomen.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: Varieties of Albuminuria.
TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Dr. R. Wells: Differential Diagnosis of Early Forms of Insanity.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir William Bennett: Surgical Aspects of Abdominal Flatulence.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).
TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations (Mr. Carson). Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting).
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie). 4.30 P.M., Lecture:—Mr. Brooks: Glaucoma.
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Demonstration:—Dr. Whipham: Selected Cases of Children's Disease.

FRIDAY.—2.30 P.M., Operations (Mr. Howell Evans). Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Dr. Thompson: Tetany.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. B. Shaw: Ultra Chronic Pulmonary Tuberculosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Mr. D. Armour: Surgery of the Nervous System.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Collier: Aphasia.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. W. Stuart-Low: Accessory Sinuses.

FRIDAY.—3.45 P.M., Lecture:—Dr. A. Wylie: Larynx.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Bullous and Vesicular Eruptions (continued)—V., Herpes; VI., Zoster; VII., Dermatitis Herpetiformis.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. F. C. Moore: Uræmia. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (14th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.20 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (15th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor. 9 A.M., Major, 2 P.M.).

SATURDAY (17th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

A Lecture
ON
THE AFTERMATH OF EYE-STRAIN.

Being the Richard Middlemore Post-Graduate Lecture, delivered on Dec. 1st, 1910, at the Birmingham and Midland Eye Hospital,

BY SYDNEY STEPHENSON, M.B., C.M. EDIN., D.O. OXON., F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE QUEEN'S HOSPITAL FOR CHILDREN AND QUEEN CHARLOTTE'S HOSPITAL.

GENTLEMEN,—Among the minor ills of life few occupy a more important place than those which arise from eye-strain. Many a headache, many an attack of giddiness, many an instance of "brain-fag," and many a so-called "nervous breakdown" tells only too surely of an unsuspected error of refraction, or of subnormal accommodation, or of a muscular imperfection of the eyes, all of which may be relieved by suitable spectacles. These cases come in the first instance under the notice of the family medical adviser rather than of the ophthalmic surgeon. It is therefore a matter of no little consequence for him to be acquainted with the peculiarities of eye-strain, so that patients may be freed from their discomfort in the speediest possible way. What I have to say will not deal with those physical peculiarities of the eye which give rise to the several conditions known as hyperopia, myopia, or astigmia. They have been made the subject of a former Middlemore lecture by Mr. Henry Eales.[1] On the contrary, my remarks will deal with the several conditions known and believed to result from eye-strain, and in describing them I shall touch upon the evidence on which our knowledge is based.

GENERAL REMARKS.

1. *How to recognise symptomatic eye-strain.*—Whenever a headache, migraine, vertigo, or "tic" is induced or made worse by use of the eyes and relieved by rest we may safely assume it is due to eye-strain. That supposition is strengthened (paradoxical though it may seem) if the patient possesses sight which when estimated by the test-types is found to be normal or super-normal. It is a suspicious circumstance if headache is complained of after a visit to a theatre or a picture gallery, or a journey by train, tram, or car. There is more than the proverbial grain of truth in the epigram of an American physician who remarked that there was nothing particularly characteristic about the headache of eye-strain, except that the subject rarely suspected that his eyes were at fault. This point has been emphasised anew by Dr. James Hinshelwood, of Glasgow.[2] Then there is the fact that an ocular reflex can often be inhibited for the time being by putting a drop of atropine (or other cycloplegic) into the patient's eyes. Lastly, it can scarcely be repeated too often that no eye can be pronounced to be normal unless its refraction has been estimated by a competent surgeon under the influence of a cycloplegic.

2. *The kind of patient.*—Slight errors of refraction are most likely to cause distress in persons who have inherited or acquired an unstable nervous system, the "neuropathic" disposition, as Dr. George T. Stevens called it.[3] In my opinion, this factor dominates the entire question of eye-strain, especially in its severer manifestations. Women and children suffer more readily than men, among whom the highly strung are the more liable. The higher classes are more prone than the lower; the cultured than the uncultured. Clerks, teachers, stenographers, dressmakers, typewriters, students, and others compelled by occupation to use the eyes for hours at a time are particularly subject to the symptoms of eye-strain. The general health of the patient is by no means devoid of influence. It is clear that an error of refraction or of muscular balance is more likely to cause distress if the patient is in poor health, as from influenza, or debilitated, as from lactation or recent confinement. It is not uncommon for the trouble to disclose itself for the first time under such circumstances, even although the underlying ocular defect may have existed from childhood or even have been congenital.

3. *How eye-strain shows itself.*—By common consent, headache is the commonest reflex manifestation of eye-strain. It has been variously estimated that headaches of ocular origin form from 60 per cent. to 90 per cent. of all cases of headache. In an analysis of 106 instances of reflex neuroses probably due to the eyes, Dr. H. B. Ellis[4] found that headache was present in 87·7 per cent., digestive and assimilative disorders in 5·7 per cent., blind spells in 3·8 per cent., mental symptoms, loss of memory, &c., in 1·9 per cent., and insomnia in 0·9 per cent. The late Mr. Simeon Snell[5] found that of 800 consecutive refraction cases that came under his notice 162—that is, about 1 in every 5—sought advice in consequence of headache.

4. *The kind and magnitude of the error.*—Of all errors of refraction slight grades of hyperopia, and particularly of hyperopic astigmatism, are those most likely to cause distress. The tendency is greatly increased if the error be asymmetrical as regards the axis of the cylinder or be unequal in the two eyes. On the other hand, myopic defects usually produce poor sight rather than the common reflex manifestations of eye-strain, such as aching eyes or head.

The results of strain are more likely to occur when the underlying error of refraction is so small that it can be mastered for the time being by action of the ciliary muscle. To put the matter in another way, a large error of refraction, which cannot be overcome by those means, leads, as a rule, to defective sight and not to eye-strain. "The smaller the error," it has been aptly said,[6] "the more likely is eye-strain to be present, and also, unfortunately for the patient, the more likely is it to be overlooked."

Patients with eye-strain, then, seldom show any serious departure from normal when their relative visual acuity is estimated at Snellen's test-types, an important point for the physician to bear in mind.

5. *Method of estimating the error.*—The days are fairly outlived when it was seriously taught that an astigmatism of less than 1·00 D., provided it caused no interference with sight, might be safely disregarded. It is now recognised that under some conditions an amount of astigmatism of no more than 0·25 D. or even 0·12 D. may cause intense discomfort. For the detection of such small errors our means of examination can scarcely be too accurate. It goes without saying that the surgeon himself must be well versed in refractions. He must be equipped with suitable lenses, correctly designed trial-frames, and properly illuminated and drawn test-types, and he should be expert in the use of the retinoscope and of other instruments of precision, such as the keratometer. Everything hinges upon exactitude. "It is the little, the inconsiderable thing, in refraction work upon which the relief of the reflexes depends" (George M. Gould[7]).

Now the precise determination of ametropia, especially the low degrees of ametropia, is not possible, I believe, unless the eyes be under the influence of some agent, as homatropine, hyoscin, or atropine, which is capable of paralysing the ciliary muscle, a cycloplegic in fact. In no other way, to my thinking, can the full measure of the defect be disclosed. In young persons, indeed, the accommodation is so active that it may conceal a hyperopia of several diopters, to say nothing of a considerable degree of astigmia. To a certain extent the remark is true of older patients also. Not only must the cycloplegic be of the right kind, but it must be applied until accommodation is placed wholly in abeyance, a point that should always be ascertained by means of a suitable test. Speaking generally, the most trustworthy results are obtained when the selected drug is applied to the eyes by the surgeon himself.

SPECIAL REMARKS.

The ground having so far been cleared, we may now pass forward to consider in some detail those symptoms, general and local, which may result from eye-strain.

Although astigmatism was described more than a hundred years ago by Thomas Young,[8] yet our knowledge of its

pathological significance dates only from 1874, when Dr. S. Weir Mitchell,[9] of Philadelphia, published a remarkable article on the subject. Dr. Mitchell minimised the influence of rheumatism as a cause of headache and denied that of gout altogether. In particular, he directed attention to the headache of unsuspected eye-strain. He pointed out that "headaches come with many intraocular disorders, but neither in the books on the eye nor elsewhere is it made plain that headaches may be for years almost the sole symptom of grave disorders of accommodation, or of defect in the orderly action of the external eye muscles." In cases of chronic headache Dr. Weir Mitchell[10] insisted upon the necessity of "a careful study of the eye," and thereby laid future generations under a heavy debt of gratitude. In the following year Dr. Mitchell published his well-known "Notes on Headaches," in which he drew attention to the influence of illness, worry, anxiety, and so forth, in converting a latent defect of the eyes into one that produced active symptoms, as shown by headache and a sense of strain. About the same time as Dr. Mitchell's second paper was published an extraordinary case (which has since become almost classic) was brought before the Clinical Society of London by Mr. R. Brudenell Carter.[11] An undergraduate, whilst reading for honours, was suddenly attacked with diplopia, vertigo, headache, sickness, and palpitation of the heart, which were attributed to some obscure affection of the brain, a diagnosis confirmed by physicians both at the University and in London. The patient was sent on a voyage to Australia but came home no better. He was then told that he must give up all hope of succeeding to his father's business and abandon a marriage engagement to which he was committed. His prospects in life were blighted, and his despondency was commensurate with his misfortunes. Mr. Carter found this unfortunate young man to be short-sighted to the extent of 4·5 D., and after suitable spectacles were prescribed, all symptoms disappeared. It is satisfactory to add that when last heard of the patient was about to engage both in business and in matrimony.

A very suggestive case was reported by Dr. Weir Mitchell[12] in 1876. A girl, aged 16 years, suffered from headache, induced by use of the eyes, for several days after each of her periods, and at a later stage she developed an occasional unsteadiness of gait, together with a sudden sense of terror and vertigo. Her rest was broken and disturbed by dreams. By the aid of the ophthalmoscope a condition of "cerebral anæmia" was diagnosed. Under the use of glasses the vertigo at first grew worse, but soon it and the headache and insomnia passed away, so that in a month she was able to read, sew, and write for hours at a time.

In an oration delivered before the Medical Society of London in 1877 Dr. J. Hughlings Jackson[13] spoke of cases of abnormal refraction simulating brain disease, and he instanced the case of a medical student, 21 years of age, who had been obliged to give up his work because it brought on attacks of frontal headache and vomiting. To ordinary examination vision appeared to be good, but on remedying the hyperopic astigmia discovered on more complete examination the patient was enabled to return to his work and to graduate at the University of London. He had remained well up to the time Dr. Jackson wrote, a period of two years.

These communications drew the attention of the medical profession to the fact that headache was a common manifestation of overtaxed eyes, and that it might be accompanied by even more ominous symptoms. This enlightenment means a good deal, for, truth to say, many a member of the public goes direct to the ophthalmic surgeon when he finds that use of the eyes tends to make his head uncomfortable.

The functional headache of eye-strain is commoner than is generally thought. Pain may be present in almost any degree of severity, but is apt to be described by patients as a "dull aching" with paroxysms of more acute suffering from time to time. Although there is no characteristic position, yet the commonest site of ocular pain is over the brow and next to that in the temple. Occipital, vertical, and general headaches are by no means unknown as the direct consequence of strain upon the eyes. The cephalalgia is often associated with pain at the back of the eyes, which are apt to be tender. As a rule, both eyes suffer equally unless there be a marked difference in the refraction, when in common experience discomfort is usually worse on the side of the better eye. Apart from actual pain, the eyes may feel heavy, tired, or become red after use, or there may be complaints that they throb, burn, or water. A sign almost conclusive of eye-strain is the existence of slightly reddened eyelids, about the lashes of which are to be seen a number of fine branny scales. Whenever this condition (sometimes called "ametropic blepharitis") is seen we should at once think of asthenopia. An outbreak of small styes, too, is often a guide to the existence of eye-strain, and so is frequent blinking, with or without slight facial contortions, liable to be mistaken for chorea, of which something will be said later.

Apart from these considerations, the cardinal diagnostic point is that pain, whatever its exact site and nature, is brought on (or, at least, rendered worse) by using the eyes, it may be, for reading or, especially in the case of muscular errors, for distance. That those who suffer from ocular headache sometimes suffer also from disordered general health cannot be looked upon as extraordinary. Such complaints as insomnia, confusion of thought, inability to fix the attention, irritability of temper, and gastric disturbance are not rare, and those symptoms, like the headache, may often be relieved by suitable glasses.

Insomnia was cited a good many years ago as a symptom of astigmatism by Mr. H. B. Hewetson of Leeds.[14] He quoted a case where the eyes had given much trouble during the examinational period of an Oxford man's life. After astigmatism was corrected with glasses, with an equal amount of work, the insomnia disappeared, and the whole physical and nervous state of the patient improved greatly. Dr. Ambrose L. Ranney,[15] an American physician with leanings towards ophthalmology, has quoted illustrative cases, some of a striking nature. The late Mr. Simeon Snell[16] spoke of insomnia as a frequent manifestation of eye-strain, and commented upon the fact that natural sleep speedily returned when relief had been afforded to the over-taxed eyes by correcting glasses. Indeed, cases of this sort must be familiar to every ophthalmic surgeon, and I have myself notes of quite a number. A similar remark applies to irritability of temper, confusion of thought, and nausea after use of the eyes. It is sometimes astonishing to see the improvement in temper and general health that follows the correction of even low degrees of hyperopic astigmatism, especially in children. I may say that, in my opinion, a physician who attempts to treat a patient for chronic headache without first making a careful examination of the eyes fails in an elementary duty.

That migraine is often closely associated with ocular defects is no new observation, since the connexion was recognised by Piorry[17] 75 years ago, and since then has been commented on by many writers, including Airy, Liveing, Ranney, Hewetson, Lauder Brunton, Stevens, Gould, Clarke, and Snell. Indeed, in 1882 Dr. Savage[18] of Jackson, U.S.A., announced that he had discovered the "real cause" (*sic*) of sick headache to be hypermetropia and astigmatism, and consequently that its successful treatment lay in the use of proper glasses. A few years later our own countryman, Mr. H. B. Hewetson[19] laid stress upon the fact that correction of the eyes by cylindrical glasses relieved not only the headache but also the intermediate dyspepsia, insomnia, and irritability of temper liable to occur in some patients between the attacks of megrim. In the following year Dr. Ambrose L. Ranney[20] stated that "the symptoms of sick headache are reflex in character to a large extent, and due primarily in almost every case to some optical defect"; and, again, in 1892 he said that he had yet to encounter a typical sick headache not associated with eye-strain.

Nowadays, few would probably care to go so far in their

statements as Dr. Savage and Dr. Ranney,[21] although every experienced ophthalmic surgeon knows that many cases of migraine are closely connected with eye-strain. Speaking for myself, I could quote case after case of the relief or cure of migraine by the use of spectacles, but I shall content myself by placing on record my conviction that, as a matter of routine practice, the eyes should be examined in every case of sick-headache. In children it appears that migraine may be replaced by bouts of vomiting, as I have pointed out elsewhere,[22] and that some of these cases yield to the correction of associated ametropia. The following is a case in point: A boy, 8 years of age, had been subject for six years to fits of violent and prolonged vomiting, which came on every fortnight or so. The attacks generally supervened at 5 or 6 o'clock A.M., and lasted, as a rule, the entire day, but on occasion they had been known to persist for as long as three days. The emesis occurred independently of food, and the vomited matters consisted mainly of "frothy, white water." On close questioning the lad stated that now and then the vomiting was preceded by headache, although usually the former occurred alone. The patient's mother, maternal grandfather, and a maternal aunt all suffered from ordinary sick headache. The lad's sight was equal to one-half normal, and relief followed the constant use of correcting glasses. In some of these patients vomiting is replaced after the advent of puberty by migraine of a more or less typical description. What connexion, if any, such cases have with the curious condition known as "cyclic vomiting" in children, believed by some to be due to acetonæmia, would be an interesting subject for inquiry. There are certainly points of resemblance between the two.

Vertigo as a consequence of eye-strain is a symptom that is more likely to take a patient to a general physician than to an ophthalmic surgeon. That it occurs is undoubted. It appears to be more common in women than in men. I can recall some striking instances of its cure by the correction of astigmia and especially of vertical deviations of the eyeball, hyperphoria. Thus, a gentleman occupying an important judicial position was so tormented with giddiness that he entertained serious thoughts of resigning his office. The symptom was entirely relieved by correcting the hyperopic astigmia and anisometropia from which he suffered. Mr. C. E. Pronger[23] mentions a very similar case. The patient developed curious attacks of giddiness which came on when awakening from sleep and produced an unconscious condition that lasted for about 15 minutes and that was followed by a violent headache. Bromides, suggested by a London specialist, availed nothing. The result of glasses, however, was most satisfactory.

Most of the remaining effects of uncompensated eye-strain may be grouped as neuroses—that is to say, as nervous affections of a functional nature. One phase of the functional neurosis known as "habit-spasm" is commonly caused by ocular strain. It is liable to be confused with chorea, a point that doubtless accounts for some of the cases of so-called "chorea" stated to have been cured by glasses. Habit-spasm occurs chiefly in sparse and nervous children from 5 to 12 years, and usually shows itself by jerking movements of the eyelids, often accompanied by a drawing-up of the angle of the mouth. Less frequent symptoms are a trick of suddenly turning the eyes upwards or downwards, or of closing one eye. These signs often make up the sum-total of the ailment, but there may be convulsive movements of the tip of the nose, the forehead, shoulders, arms, hands, or legs, or a tendency to make uncouth noises. In many cases, more especially those in which blinking is the chief symptom, the correction of even a trifling error of refraction will check the "tic," as the condition is sometimes called. Atropine dropped into the eyes has sometimes the same effect. Elsewhere[24] I have reported a series of these cases, and in doing so I laid stress upon four points, which I venture to repeat in this place. They are as follows: (1) Such children seldom complain of eye-strain, an omission that is likely to mislead the practitioner; (2) their sight is usually good; (3) no dependence whatever should be attached to an estimation of refraction unless the eyes at the moment of examination are fully under the influence of atropine; and (4) the ametropia should be corrected almost fully by glasses to be worn for every purpose.

[24] Sydney Stephenson: Brit. Med. Jour., Sept. 18th, 1909, p. 751.

The following case appears to support the claim recently made by Mr. R. W. Doyne[25]—namely, that polyuria may be a manifestation of eye-strain. A thin and nervous man, aged 35 years, consulted me on account of painful eyes, which when bad were accompanied by nausea and followed by the passage of large amounts of pale urine. The condition had been present for five or six years. The full correction of compound myopic astigmatism (*minus* 1·0 D. sph. with *minus* 1·5 D. cyl. axis 80°) by spectacles for constant wear was speedily followed by loss of the headache and eventually of the polyuria. The patient himself was convinced that the glasses were responsible for his cure, although it is obviously impossible to exclude the influence of suggestion.

When we come to epilepsy and its relationship to eye-strain we enter upon debateable ground. That the characteristic convulsions may result from abnormal conditions of the eye has been warmly affirmed and hotly denied. Although I can make no personal contribution to the discussion, I can at least briefly describe the experiences of some other observers, and ask my hearers to draw their own conclusions as to the reality of the connexion. In 1887 Dr. Stevens and Dr. Ranney reported cases of epilepsy cured by glasses or by operations upon the external eye muscles. Somewhat later Dr. Wendell Reber[26] of Philadelphia described several instances of the same disease cured by glasses. Dr. George M. Gould[27] gave particulars of six such patients cured by glasses, and other American writers, as G. H. Thomas, Samuel Theobald, Myles Standish, Zimmerman, Gallaher, Semple, and Hubbell, have reported that in their experience epileptic attacks are either cured or reduced in number by the provision of proper glasses.

Opposing evidence was furnished by the commission appointed in 1887 by the New York Neurological Society to examine the claim made by Dr. George T. Stevens—namely, that ocular disturbances were "among the most prolific sources of nervous disturbances, and more frequently than other conditions, constitute a neuropathic tendency." After having investigated nine test cases, the commission reported that no single instance could be cited in which the cure of genuine epilepsy had followed correction of refractive or muscular errors of the eye. Of the cases three were improved, five remained without improvement, and, finally, in one the result was unknown. In view of these facts, the commission expressed the view that the method did not afford a sufficient degree of relief to patients to warrant its adoption or recommendation as a means of cure or as the sole therapeutic measure. Dr. Stevens[28] replied by alleging bad faith on the part of the commission, which, in addition to himself, included two members of his own nomination. He furthermore spoke of the report as "*ex parte* and objectionable in spirit and motive." Dr. Gould[29] dismisses the findings of the Stevens Commission with these contemptuous words: "One may summarise the results of this commission as being, perhaps, as worthless as the reports criticised."

Dr. William P. Spratling[30] has given an account of experiments carried out at the Craig Colony of Epileptics, Sonyea, New York—an institution of which he is the medical superintendent. Sixty-eight patients (mostly young or middle-aged adults) were selected for experiment—a number that included 35 men and 33 women. Attacks were tabulated for a period of three months previous to the use of correcting glasses, and again for periods of three, six, and 12 months after their employment. The ocular examinations (conducted under homatropine and cocaine) were carried out by Dr. George M. Gould, assisted by Dr. Arthur J. Bennett of Buffalo. The glasses were prescribed by Dr. Gould, and with few exceptions were worn from Sept. 1st, 1902, to Sept. 1st, 1903. The results obtained in 66 of the cases were as follows: (1) In one case there was an arrest of the attacks and cure seemed probable; (2) in 11 cases there was an apparent decrease in the attacks; (3) in 16 cases there was no change; and (4) in 33 cases the attacks increased.

The validity of the Craig Colony experiment has been

challenged by Dr. Gould, who speaks of "the confused and untrustworthy statistics of the official report," and criticises the absence of a resident oculist or optician to supervise the after-treatment of the cases. To quote his own curious words, Dr. Gould thinks he should have excluded from the list "the old hopeless patients, those on the verge of the grave, and hence incapable of convulsions after death." A bit of interesting evidence has been furnished by Dr. Hodskins and Dr. Moore,[31] who kept the eyes of 88 epileptics under the influence of atropine for a month. For the atropine months the seizures averaged 12·6 per patient, as compared with 13·2 for the average month. The authors firmly "believe that the rôle played by ocular defects in the causation of epilepsy is a very modest one." Finally, Dr. B. Sachs[32] does not know "of a single case in which epileptiform seizures have been altogether inhibited or even diminished in number by the wearing of glasses, by the cutting of muscles, or by any other ocular measures which have been adopted."

In our own country the ocular origin of some cases of epilepsy has been endorsed by several writers. To Mr. H. Work Dodd[33] we are indebted for a most important contribution dealing with the treatment by glasses of 100 consecutive cases of epilepsy at the West End Hospital for Nervous Diseases and Paralysis, London. All but three of the patients were examined with the eyes under the influence of a cycloplegic (atropine or homatropine). Into the carefully tabulated results we need not enter here. It is of more importance for our present purpose to note that 52 of the patients were ordered to wear glasses, and of that number 13 developed no fits during periods that varied from 4 to 12 months. In 36 other patients the condition was improved under glasses and three patients remained *in statu quo*. In reference to these somewhat striking figures, it is to be remarked that the usual medical treatment appears to have been continued in all the cases.

Mr. C. Ernest Pronger[34] makes the statement that in true epilepsy and in *petit mal* "some error of refraction is very commonly present and that the correction of it tends unmistakeably in my opinion to mitigate both the intensity and frequency of the attacks." This view amounts to little more than a pious expression of opinion and calls for no comment. But Mr. N. Bishop Harman[35] relates the case of a young lady subject to fits which "tallied well with the picture of epilepsy, save in one point—that consciousness was not lost," who experienced no further attacks after glasses had been prescribed for the hyperopic astigmia and anisometropia that were present in the case. It is unfortunate that in Mr. Harman's patient one essential of epilepsy—namely, loss of consciousness—was absent. Finally, Mr. Ernest Clarke[36] takes up the position that "the removal of eye-strain does not, in the strict sense of the word, cure epilepsy any more than it cures a headache, but by removing the eye-strain we remove one of the causes, and frequently the only cause, that determines an attack." Few will be found to join issue with this eminently reasonable proposition.

All things considered, I cannot help thinking that there is a case for further investigation into the relationship between eye-strain and epilepsy. In any such investigation it is to be hoped that three precautions will be adopted: (1) to make sure that the disease is true epilepsy and not a mere hysteroid convulsion; (2) to treat the patient by glasses alone; and (3) to observe the case not for weeks but for years.

In his famous "Biographic Clinics" Dr. George M. Gould, now of Ithaca, has shown with more or less likelihood that the "irritability," "nervousness," and general ill-health of some of our greatest writers and thinkers was the functional result of undetected eye-strain. Dr. Gould's list includes such names as those of de Quincey, Carlyle, Darwin, Huxley, Taine, Browning, Wagner, Balzac, Whittier, Flaubert, Spencer, Hearn, Chaikovsky, and Nietzsche. It cannot, indeed, be doubted that in some neuropathic individuals (the class from which great writers are mainly recruited) the eyes are accountable for a host of troubles, which range from "nervous breakdowns," mental apprehension, and agoraphobia, on the one hand, to the manifestations of neurasthenia or of actual mental disorder, on the other. At the same time such cases (which are far from common in my experience) occur only in nervous, highly-strung individuals. Dr. Samuel D. Risley[37] has recently pointed out that the ocular defects present in these psychoses are precisely those which are frequent in other patients, and he has laid particular stress on the fact that for the production of the symptoms another factor is essential—namely, an unstable nervous system, inherited or acquired. Again, there is always the influence of "suggestion" to be thought of. It is certain that an ophthalmic surgeon deeply imbued with a belief in the efficacy of glasses will do more with this particular class of patient than his equally competent brother whose enthusiasm is perchance tempered with a calmer judgment. Indeed, all things are possible to the eye of faith. But the hard fact remains that relief can be given to a certain number of these patients by careful attention to the eyes, a point that in my opinion merits more attention from the practising physicians than it has yet received, especially in this country and on the continent of Europe.

An example of a minor psychosis due to the eyes is well exemplified in a case related by Sir Lauder Brunton.[38] A patient consulted that distinguished physician complaining that he was losing his head. He had a large business, and whenever he sat down to his account books he could manage pretty well for five minutes, and then (he said) everything seemed to go round and he could not add two and two together. This patient's eyes were presbyopic, and his symptoms speedily yielded to a pair of spectacles. A case recently published by Dr. Wendell Reber[39] is even more striking. A girl, aged 25 years, suffered from dull occipital headache, and after reading and sewing, from vertigo and nausea, with a feeling "as though her head would burst." She became morose and depressed and began to fear she was losing her mental balance. She was distressingly thin, poorly nourished, and markedly neurasthenic. After correction of her hyperopic astigmatism by glasses she gained 18 pounds in six months and lost all her symptoms.

To the foregoing I may be permitted to add one or two illustrative cases that have come under my notice. The first is one of agoraphobia definitely cured by glasses. A woman, aged 30 years, who had always been subject to "blind headaches," complained that for the last 18 months she had become giddy on turning a corner or on passing into the light. During the last six months she had gradually developed a fear of open spaces. This symptom had become so marked that she was now unable to cross even an ordinary street, but if accompanied by a friend the feeling of fear was slight. In the right eye there was slight hyperopic astigmia, and in the left slight hyperopia. A prism of $\frac{1}{2}$ D. base out was required to produce fusion of distant objects. In the first four months, during which glasses were worn constantly, the giddiness and agoraphobia were entirely lost. Glasses were then used for reading alone, and there was a return of the symptoms, which again disappeared when they were worn constantly. In 1906 the lady suffered from pain behind the sternum ("inward neuralgia" was the diagnosis of her physician) for six months, during which period she had two slight attacks of agoraphobia, but no return of vertigo. With that exception the patient, who has been under observation since October, 1905, has remained free from any anxiety when crossing open spaces, no matter how wide.

The second case is one of periodic attacks of nausea, vertigo, and retching, lasting with intermissions for several hours, and sometimes followed by intense headache persisting for 24 hours. The attacks, which always began at night when the patient was in bed, had been present for about six years, and were getting worse when I saw the case in 1907. The patient, a man, aged 38 years, was in a highly nervous state, incapable of work, and apprehensive of all kinds of impending misfortune. Glasses prescribed in South Africa had done no good. A London physician had suggested that the underlying condition might be one of obscure intracranial mischief. Briefly, there was hyperopic astigmia against the rule, with a considerable difference between the

two eyes, and complete recovery of health followed the constant use of glasses which corrected the refractive error almost completely.

There would be little difficulty in multiplying such cases as the foregoing, but enough have been given to show the importance of examining the eyes in these curious psychoses. If this be done we shall sometimes succeed in ridding patients from distressing symptoms but little under the influence of ordinary remedies.

The manifestations that in my personal experience uncompensated asthenopia may produce have now been described, but in that of others the list is by no means exhausted. Many other conditions have been assigned to the same cause, although not always, I think, upon adequate evidence. Among these conditions may be mentioned dysmenorrhœa (A. Doran F. Hare), tachycardia (de Schweinitz), sleepiness (Doyne), enuresis (Gould, A. H. Fardon), sea-sickness (Pronger), night terrors (de Schweinitz), constipation (L. Williams), tinnitus (Theobald), Ménière's disease (F. P. Lewis), dermatitis (T. H. Butler), sinusitis (W. L. Phillips), appendicitis (R. T. Morris), and pre-tuberculosis (F. P. Lewis), to say nothing of head-tilting and spinal curvature, and, more startling still, of the drug habit, crime, insanity, and suicide. Some of these suggestions seem more than a little far-fetched.

THE SPECIFIC DIAGNOSIS OF PULMONARY TUBERCULOSIS.[1]

BY A. C. INMAN, M.A., M.B. OXON.,

SUPERINTENDENT OF THE LABORATORIES OF THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

THE diagnosis of early pulmonary tuberculosis is so important, both from the point of view of the physician who is asked to express an opinion and of the patient who asks for this opinion, that a review of the recent methods which may conduce to an accurate diagnosis of this disease is worthy of careful consideration. It must be understood that what we are striving to obtain is a method, or combination of methods, which will specify tuberculosis of the lungs which calls for treatment. The tubercle bacillus is ubiquitous and all-invading, but fortunately for the human race not all-conquering. The classical investigations of Nägeli have clearly shown that practically all individuals over 30 years of age have been brought into conflict with this bacterium. I am convinced that the ultimate results of all the scientific work which is being devoted to the study of pulmonary tuberculosis will go far to explain the methods of natural cure which takes place in many cases, and will expose the effects on the animal economy to which such an invasion inevitably leads.

A generation has hardly passed since Koch, whose death the scientific world still mourns, conclusively proved that the bacillus tuberculosis which he described is the sole cause of tuberculosis. The presence of this bacillus in any focus of disease or in the output of any such focus is recognised as irrefutable proof of the tuberculous nature of the disease.

The presence of tubercle bacilli in the sputum is absolutely diagnostic of pulmonary tuberculosis if primary disease of the upper air-passages, which is very rare, can be excluded. It follows that as regards the diagnosis of pulmonary tuberculosis the examination of the sputum for tubercle bacilli is of the first importance. Such an examination is now universally practised as a routine method, and yet there are considerations which, though not generally recognised, are worthy of attention in this connexion. It is important to examine carefully whenever possible the early morning expectoration—that is to say, the first sputum expectorated after the night's sleep. Careful search of such a specimen has often been rewarded by a positive result after numerous negative examinations of specimens collected at random during the day-time. For routine examinations the sputum supplied should be spread out on a piece of glass against a dark background and carefully searched for yellow purulent foci, from which films are made. These are dried by agitation in the air or by subjection to moderate heat and stained by the Ziehl-Neelsen method (warm carbol-fuchsin, which should not be heated to ebullition, decolourised with 25 per cent. sulphuric acid, and counter-stained with 1 per cent. aqueous methylene blue). A single negative examination is quite inconclusive, for which reason the routine adopted at this hospital has been to examine three specimens collected on separate days in all doubtful cases.

Carl Spengler (1) has advocated the use of picric acid as a mordant for the fuchsin in addition to the carbolic acid, and in this way claims to have demonstrated tubercle bacilli in sputa in which their presence was not revealed by the Ziehl-Neelsen method.

Method.—Stain films with carbol-fuchsin. Pour off the stain and add picric acid-alcohol for 2-3 minutes. Wash with 60 per cent. alcohol, add 3-4 drops of 15 per cent. nitric acid, wash with 60 per cent. alcohol, and counter-stain with picric acid-alcohol until the films are coloured yellow. Wash and dry.

Mr. R. C. Styles, F.I.C., has carefully investigated this method in the Brompton Hospital Laboratory, and was unable to demonstrate tubercle bacilli in any specimens of sputum in which no tubercle bacilli had been found by the routine method. He showed, however, that in nearly all cases more tubercle bacilli were demonstrable by this procedure than by the Ziehl-Neelsen method.

By the above methods only part of the sputum supplied is examined microscopically. In the event of three searches proving negative the whole quantity of sputum available should be examined by one of the methods of concentration. For this purpose the older manners of proceeding—such as homogenisation with caustic potash, or agitation in carbolic acid, subsequent spinning in the centrifuge, and examination of the deposit—have been superseded by the following improvements in technique.

1. The ligroin method of Lange and Nitsche (2).

Place 5 c.c. of sputum in a conical flask and add 50 c.c. of caustic potash (5 per cent.). Shake vigorously and allow the mixture to remain at room temperature until the sputum is thoroughly homogenised. Dilute with 50 c.c. of tap water and shake again. Then add 2 c.c. of ligroin and shake vigorously until a thick emulsion is produced. Warm the mixture to 60° C. until distinct separation of the hydrocarbon occurs as evidenced by effervescence and the formation of a superficial layer of small bubbles. A number of drops are then taken from immediately below this superficial layer with a platinum loop and placed on a warm slide. The dry film is then fixed with a saturated solution of perchloride of mercury and stained by the Ziehl-Neelsen method.

Ligroin is petroleum ether obtained by the fractional distillation of petroleum. Mr. Styles also investigated the utility of this method and was able to demonstrate tubercle bacilli in four cases from 50 samples of sputum which had yielded a negative result with the routine method.

2. The antiformin method of Uhlenhuth and Xylander (3).

The sputum is homogenised with 15 per cent. antiformin (a mixture of equal parts of sodium hypochlorite and sodium hydrate, obtainable from Oskar Kühn, Berlin). The mixture is sedimented in a high revolution centrifuge. After decanting the supernatant fluid the deposit is washed in physiological salt solution and again centrifuged. Films are then made from the resulting deposit, dried, fixed in perchloride of mercury, and stained by the Ziehl-Neelsen method.

This procedure is quick and very effective. It needs but a short acquaintance with it to be convinced of its superiority over other methods.

3. Loeffler (4) has recently suggested an ingenious modification of the antiformin method which is worthy of mention. Availing himself of the high specific gravity of chloroform (sp. gr. 1497) his modification is as follows:—

To 5–20 c.c. of sputum is added an equal quantity of 50 per cent. antiformin. The mixture is heated until a clear liquid results. To 10 c.c. of this mixture is added a 10 per cent. solution of chloroform in alcohol (5 c.c. generally suffice). After thorough shaking the fluid is centrifuged for 15 minutes. An opaque layer is then found to exist between the chloroform which occupies the bottom of the centrifuge and the supernatant fluid. The latter is pipetted off and the intermediate opaque layer removed wholly on to a slide. Films are made, dried, fixed, and stained.

The method yields excellent results, is rapid, and simple. When employing any of the above concentration methods it must be borne in mind that living virulent bacilli are being dealt with and precautionary methods of disinfection of the hands, test-tubes, and instruments used must be adopted.

Rosenberger (5) startled the medical world by announcing that he had found tubercle bacilli in the circulating blood of the majority of consumptive patients even in the earliest stages of the disease. The positive results of this observer have not, however, been confirmed by the majority of workers on this subject. Lippmann (6), taking 10 c.c. of blood from the patient and adding to it 30 c.c. of acetic acid (3 per cent.), made an emulsion of the deposit produced by centrifuging this mixture. To the emulsion he added 60 c.c. of antiformin (15 per cent.), incubated it for one hour at 37° C., and then sedimented the solid particles by centrifuging. In films from the deposit he found tubercle bacilli in the following percentage of cases with reference to the stage of disease:—Third stage, in 53 per cent. of cases;

[1] Founded on a lecture delivered at the Brompton Hospital on Nov. 9th, 1910.

second stage, in 33 per cent. of cases; and first stage, in 0 per cent. of cases (one case).

Schnitter (7), examining the blood of 34 cases of tuberculosis, found tubercle bacilli in 10 cases. He agrees with Liebermeister that the presence of tubercle bacilli in the blood implies a grave prognosis and suggests impending death. His cases were divided as follows:—

	No. of cases.	T.B. in blood.	
Third stage	17	8	47 per cent.
Second stage	9	2	22 ,,
First stage	8	0	0 ,,

Ravenal and Smith (8) were unable to find tubercle bacilli in the blood of 18 cases of tuberculosis examined.

Jessen and Lydia Rabinowitsch (9) found tubercle bacilli in the blood of 12 cases of third stage in 5 cases (Much's granules in 1 case); 12 cases of second stage in 0 cases (Much's granules in 2 cases); and 12 cases of first stage in 2 cases.

Hunt (10) examined the blood of 20 patients for tubercle bacilli. Of these, 13 had tubercle bacilli in the sputum, one had been diagnosed as tuberculous peritonitis, one as tuberculous laryngitis, and five were under suspicion of being tuberculous. Of smears made from the blood of 19 patients, 15 gave negative results as regards acid-fast bacilli. Of the remaining four bloods (two from cases with tubercle bacilli in the sputum, one case diagnosed as tuberculous peritonitis, the other suspected to be tuberculous), in one the films were only decolourised with 2½ per cent. sulphuric acid, in two the acid-fast bacilli were morphologically unlike tubercle bacilli; whilst in one case, in which a clump of bacilli resembling the tubercle bacillus was found, the inoculation into a guinea-pig of the remainder of the blood did not produce tuberculosis. Eleven guinea-pigs were inoculated with the blood from ten cases. At the necropsies performed on these animals after a natural or unnatural death, no evidence of tuberculosis was detected in any of them. Dr. MacNalty is at present investigating this subject at the Brompton Hospital, and I am permitted to say that so far his results cannot confirm those of Rosenberger.

Latterly, attention has been paid to the examination of the fæces for tubercle bacilli. The antiformin method is especially suited to such examinations.

Method.—A portion of fæces, about 1 cubic inch, is placed in 20 c.c. of antiformin (15 per cent.). By means of a glass rod the fæcal mass can be easily broken up and a coarse emulsion produced. Another 20 c.c. of antiformin is added to the emulsion, the vessel employed is closed, and the mixture is allowed to stand for two hours. At the end of this time a creamy sediment is seen to have collected at the bottom of the vessel. Some of this layer is removed with a pipette, films are prepared with it, dried, fixed with perchloride of mercury, and stained by the Ziehl-Neelsen method. Decolourisation may be practised with alcohol (60 per cent.) in addition to the sulphuric acid (25 per cent.).

Rosenberger and Willson (11) have stated that they found tubercle bacilli in the stools of 100 tuberculous patients and of 21·5 per cent. of clinically healthy persons.

Klose (12) claims to have found tubercle bacilli in the fæces of every case of pulmonary tuberculosis in which tubercle bacilli were present in the sputum.

Philip and Porter (13) examined 109 specimens of fæces. Of these, 99 were clinically cases of pulmonary tuberculosis, 34 had tubercle bacilli in the sputum, 42 had sputum in which no tubercle bacilli had been discovered, and 24 had no sputum at all. "Of the tuberculous patients, all those with bacilli in their expectoration, with one exception, presented tubercle bacilli in the fæces. In the 42 cases in which the bacillary examination of the sputum was negative 29 gave tubercle bacilli in the fæces. Of the 24 cases without sputum, 17 showed bacilli in the stools. Of nine specimens from presumably normal subjects none yielded tubercle bacilli."

Alexander (14), having determined the dose of human fæces tolerated on injection by guinea-pigs, tried in this way to infect guinea-pigs with the fæces of tuberculous patients. In all he injected into guinea-pigs the fæces of 24 tuberculous subjects. 23 guinea-pigs died as a result of the injection of samples of fæces all of which had shown the presence of acid-fast bacilli microscopically. The twenty-fourth sample of fæces showed no tubercle bacilli at the time of the experiment, but acid-fast bacilli were demonstrated in the stools of the patient from whom this sample had been obtained after a purgative had been administered. 129 samples of fæces examined by the same observer from subjects clinically non-tuberculous revealed no tubercle bacilli microscopically.

These results suggest the applicability of this method of recovering tubercle bacilli to the diagnosis of early pulmonary tuberculosis. In conjunction with Dr. Cecil Clarke I have commenced a systematic investigation into the presence of tubercle bacilli in the fæces of clinically tuberculous, doubtfully tuberculous, and non-tuberculous patients at the Brompton Hospital. The investigation is only in an initial stage, but has so far given the following results:—

Investigation as to the Presence of Tubercle Bacilli in the Fæces of 26 Adults.

No.	Sputum.	Fæces.	Disease.
1	T.B. +	T.B. +	C.P.T., active, advanced.
2	T.B. 0 (3*)	T.B. 0	C.P.T., quiescent, early.
3	T.B. 0 (2)	T.B. 0	? tuberculous glands of abdomen.
4	T.B. 0 (3)	T.B. 0	C.P.T., afebrile, quiescent.

* The figure in each instance indicates the number of examinations.
† The antiformin method was employed.

Thus of 26 adults 18 had tubercle bacilli in the sputum; and of these 16 had tubercle bacilli in the fæces; and in 2 cases the examinations of the fæces gave a negative result. 8 of the patients examined had no tubercle bacilli in the sputum, and of these 7 had none in the fæces, whilst in 1 case (C.P.T., 2 lobes, afebrile) tubercle bacilli were found in the fæces. These results suggest that the appearance of tubercle bacilli in the stools of early cases of pulmonary tuberculosis, and in the absence of intestinal tuberculosis, results from the swallowing of sputum secreted in an open tuberculous focus in the lungs.

Dr. M. S. Paterson, the superintendent of the Brompton Sanatorium at Frimley, informs me that many patients have told him that it is practically impossible, however good the intention may be, not to swallow some sputum during the course of the day if this exists in any quantity. The method suggests itself as particularly useful in the investigation of children, who commonly swallow their sputum. Our available material is very limited at the Brompton Hospital, where there are but few children's beds. We have so far examined the fæces of seven children with the following results:—

Investigation as to the Presence of Tubercle Bacilli in the Fæces of 7 Children.

No.	Age.	Sputum.	Fæces.	Provisional diagnosis.
1	9 years.	–	T.B. +	C.P.T., 2 lobes, febrile.
2	7½ ,,	–	T.B. 0	No physical signs of disease.
3	2½ ,,	–	T.B. 0	? C.P.T., afebrile.
4	6 ,,	T.B. +	T.B. 0	C.P.T., 2 lobes, febrile.
5	7 ,,	–	T.B. 0	C.P.T., 3 lobes, febrile.
6	4 ,,	–	T.B. 0	C.P.T., 2 lobes, febrile, v. Pirquet positive.
7	5 ,,	–	T.B. 0	Fibrosis—? C.P.T., v. Pirquet positive.

These results are too few to admit of any conclusion being drawn from them.

If tubercle bacilli are not demonstrable in the sputum, the blood, or the fæces, inferential diagnosis must be relied upon. A number of methods have been advocated for this purpose.

1. *Von Pirquet's cutaneous reaction.*—This consists in scarifying the arm and placing on the scarified spot two drops of the concentrated old tuberculin of Koch. A positive reaction, which consists of the formation of a red papule at the site of scarification, appears at the earliest within three hours, but may not do so before 24 hours have elapsed. In some cases the interval is still more prolonged. This reaction is of value and is eminently specific in the case of young children, but it can only show the presence of latent tuberculosis in adults, for 70 per cent. of the apparently healthy give a positive reaction. Von Pirquet gives the following figures. Of 747 children tested there were :—

Clinically tuberculous, 130, of which 113 (87 per cent.) reacted positively.
Clinically non-tuberculous, 512, of which 104 (20 per cent.) reacted positively.
Doubtfully tuberculous, 115, of which 56 (48·6 per cent.) reacted positively.

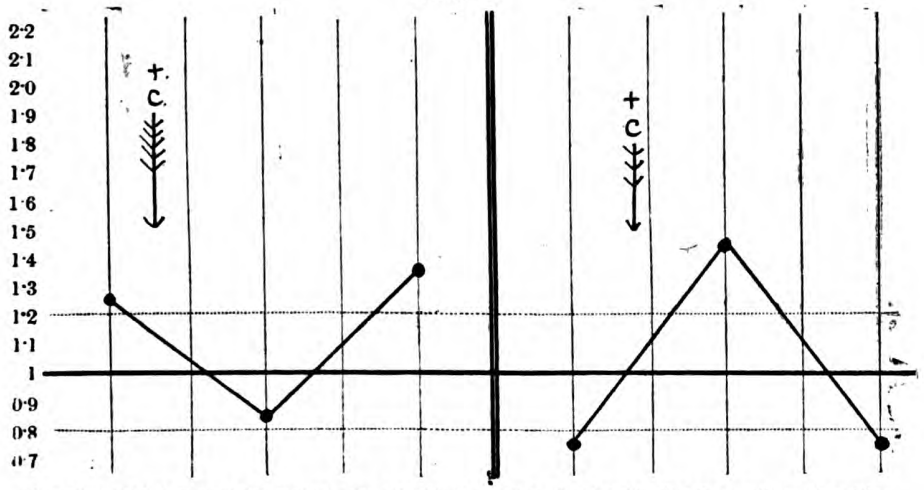
The tuberculous cases which gave a negative reaction were nearly all cachectic.

into the eye. J. Citron (16) gives the following instructive table with reference to the value of this reaction :—

—	Audéoud.	Petit.	Citron.	Eppenstein.	Schenck u. Seiffert.
Tuberculous ...	94·6	94·3	80·7	72·3	78·6
Doubtful ...	81·0	61·6	80·0	40·0	30·0
Normal	8·3	18·4	2·2	9·0	5·8
	Percentage of positive reactions using Calmette's preparation.		Percentage of positive reactions using 1 per cent. old tuberculin.		

Bandelier and Roepke (17) recommend the following as the best method of employing the ophthalmo-reaction for diagnosis: In adults place a drop of 1 per cent. old tuberculin on the conjunctiva of one eye. In the event of the reaction being negative repeat the test with the instillation of a drop of 4 per cent. old tuberculin into the other eye. These authors rightly state that if this method is used the following two facts must be borne in mind: (*a*) A positive reaction only points to the presence of a tuberculous focus in the body without giving information as to the active or inactive character of such a focus. (*b*) A negative reaction does not prove the absence of active tuberculosis.

CHART 1.



Opsonic index before and after applying the ophthalmo-reaction. C + denotes that the reaction was positive.

The older the child the less valuable becomes the reaction from a point of view of diagnosis. Von Pirquet tested apparently healthy children of all ages from one month to 15 years with the following result :—

Age.	Positive reactions.	Age.	Positive reactions.
1–6 months	0 per cent.	4– 6 years	17 per cent.
1–2 years	2 ,,	6–10 ,, ...	35 ,,
2–4 ,, ...	13 ,,	10–15 ,, ...	55 ,,

Yoshikawa (15) gives the following interesting table :—

Clinically Non-tuberculous Cases.

Age.	Number.	Positive reaction		Negative reaction.
		Marked.	Slight.	
Up to 5 years	9	1	—	8
6–10 ,, ...	8	—	—	8
11–15 ,, ...	11	1	3	7
16–20 ,, ...	17	6	5	6
21–30 ,, ...	16	6	8	2
31–40 ,, ...	21	12	8	1
Over 40 ,, ...	30	14	12	4

I have recently been asked to examine the blood for the tuberculo-opsonic index in the case of six medical men who, although apparently healthy, had given a positive cutaneous reaction, self-inflicted!

2. *The ophthalmo-reaction.*—This is best practised by the instillation of a drop of 1 per cent. old tuberculin of Koch

This reaction is absolutely contra-indicated if any eye disease is present, and even should this not be the case the degree of inflammation produced by a markedly positive reaction may be very unpleasant for the patient and not devoid of danger. Again, the reaction should not be employed if a course of tuberculin treatment has been decided on, as such a procedure is likely to light up an inflammation of the eye. Estimations of the opsonic index before and after applying this test show that even the small quantity of tuberculin employed is sufficient to cause a distinct variation in the index (Chart 1). The charts show that this variation is similar to that produced by exercise in the case of the patients at the Brompton Hospital Sanatorium at Frimley (18). Chart 2 refers to a case which came under the observation of the author. It is noticeable that the instillation of a drop of tuberculin in the eye caused a temporary rise of temperature, and that this was accompanied by a negative phase in the blood. The ophthalmo-reaction was markedly positive.

3. *The subcutaneous tuberculin test.*—The preparation used for this test is the old tuberculin of Koch, 1 c.c. of which contains 1000 mg. tuberculin. Probably the best site for inoculation is the skin of the back, close to the vertebral edge of the scapulæ. The test should only be employed on patients without fever and whose general condition is satisfactory. Obvious organic lesions of the vital

organs, recent hæmoptysis, cachexia, and fever are contra-indications. The usually adopted dosage is as follows: Initial dose, 0·0002 c.c. old tuberculin = 1/5th mg.; first increase, 0·001 c.c. old tuberculin = 1 mg.; second increase, 0·005 c.c. old tuberculin = 5 mg.; maximum dose, 0·01 c.c. old tuberculin = 10 mg.

A positive reaction is manifested by (1) a local reaction at the site of inoculation; (2) a febrile reaction; (3) a general reaction evidenced by more or less severe subjective symptoms; and (4) a focal reaction at the site of tuberculous infection (in pulmonary tuberculosis in the lung). No great importance is to be attached to the reaction at the site of inoculation. As regards the febrile reaction, one may now definitely affirm that it is not specific. The generally accepted opinion is that fever is no criterion to distinguish in any way between active and inactive tuberculosis, and merely shows that the inoculated individual is a bearer of tuberculosis.

There seems to be great divergence of opinion as to the interpretation of the febrile reaction following any given dose. Originally Koch stated that a febrile reaction produced by the injection of 10 mg. was specific, and that it was not until a dose of 25 mg. was reached that non-specific intoxication effects were produced. Since then a number of authors have cast doubt on those figures; thus, Stintzing considers 3 mg. the maximal specific dose, Beschorne places it at 5 mg., Roepke at 6 mg., Junker at 5 mg., Neumann at 5 mg., Roth-Schalz at 2·5 mg., Loewenstein and Kaufmann at 0·2 mg., von Balen at 1/100 mg., whilst others find nothing specific in the reaction at all. Latterly Gordon (19) reports on the effect of inoculating a chemically pure tuberculin (endotin), which produces no febrile reaction unless this is secondary to a focal reaction in the diseased tissues. For this reason he recommends giving up the febrile reaction as a diagnostic agent. The general reaction is to be given up for similar reasons. The focal reaction in the lungs is then the specific, and therefore valuable, sign of the tuberculin test. Sahli, Romberg, Penzoldt, Bandelier and Roepke, Meissen, Citron, among others, agree that the reaction of the subcutaneous test is a well-marked focal reaction. So that if this test is employed the lungs must be carefully examined for the appearance of crepitations, &c., and the sputum should be carefully searched for tubercle bacilli.

Consider the case of a patient on whom at some previous date the ophthalmo-reaction or the cutaneous reaction has been performed. A subsequent subcutaneous injection of tuberculin is able to light up the localised inflammation produced by the instillation of a drop of 1 per cent. tuberculin in the eye or a drop of tuberculin placed on a damaged skin, but that does not mean that the eye or the area of skin in question needs treatment. Similarly, even if a focal reaction in the lung is produced by the injection of tuberculin, it only localises the tuberculous process to the lungs. By itself it cannot indicate activity or inactivity in the focus.

It is very important that these limitations of the tuberculin diagnosis should be fully recognised. A positive ophthalmo-reaction, cutaneous tuberculin reaction, or subcutaneous tuberculin test, by itself, cannot distinguish between active and inactive tuberculosis, between tuberculosis which calls for treatment and that which does not. The only rational way of using such tests is to make them but one of the many factors which have to be taken into consideration when deciding on the important question as to the advisability or no of a course of treatment, which usually is lengthy and costly. Highly-trained clinical experience is as necessary to-day as ever it was.

Citron (20) quotes the interesting researches of Franz (21), which are worthy of consideration. This observer took 400 apparently healthy soldiers of a Bosnian regiment in 1901 and gave them all injections of Koch's old tuberculin, with a maximum dose of 0·003 c.c.; 61 per cent. of these men gave a positive reaction. Next year (1902) 100 of these soldiers were again inoculated, with the result that all those who had reacted the previous year reacted again, and in addition 14 others, making 76 per cent. altogether. 323 men were inoculated for the first time in 1902, and 68 per cent. reacted positively. This regiment is recruited from a district in which tuberculosis is rife, so Franz inoculated in a similar way a number of men of a Hungarian regiment which is recruited from a district poor in tuberculous cases, yet 38 per cent. gave a positive reaction. The same author followed out the subsequent history of the men inoculated and publishes the following interesting statistics:—

Regiment.	Date of inoculation.	Number of men inoculated.	Reaction.	During the three years service were discharged through death, ill-health, or excessive leave due to—		
				Tuberculosis.	Suspected tuberculosis.	Other diseases.
Bosnian Infantry Regiment No. 1.	1901	400	+ 245 (61%) − 155 (39%)	17 (8 deaths). 5 (4 „)	22 25	10 7 (1)
Ditto	1902	323	+ 222 (68·8%) − 101 (31·4%)	13 (6 „) 4	28 (1) 13	7 (2) 5
Infantry Regiment No. 60.	1902	279	+ 108 (38·7%) − 171 (61·3%)	4 3 (2 „)	4 5	8 12
Total ...	—	1002	+ 575 − 427	34 (14 deaths) 12 (6 „)	54 (1) 43	25 (2) 24 (1)

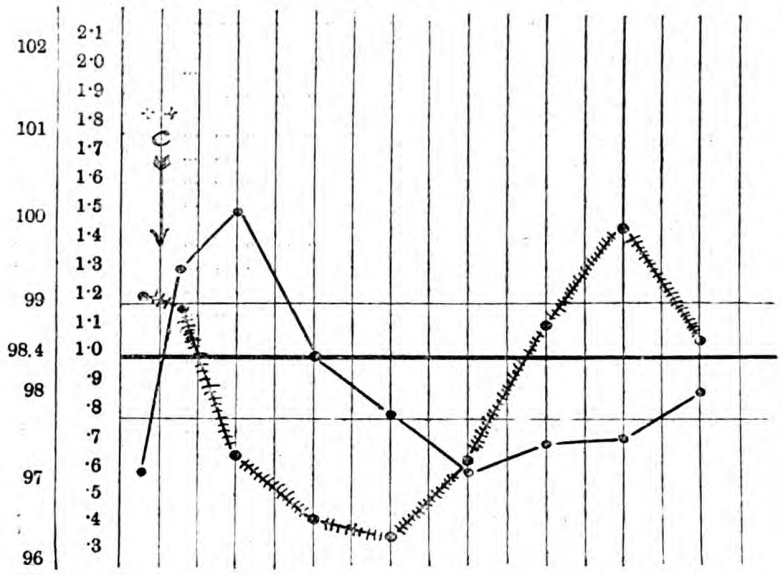
4. *Examinations of the blood serum.*—The other methods of inferential diagnosis consist in the detection of substances in the blood serum which have been elaborated by the infected organism in response to the infection. Just as specific agglutinins for the B. typhosus exist in the serum of patients suffering from typhoid fever, and for the M. melitensis in the serum of patients suffering from Malta fever, so in a certain percentage of cases are found specific agglutinins for the B. tuberculosis in the serum of patients suffering from tuberculosis. Unfortunately, the regularity with which those substances are produced and their quantity in the serum are not sufficiently great to allow of this test being applied to the early diagnosis of pulmonary tuberculosis. Again, the complement-fixing substances, which have assumed so important a rôle in the diagnosis of syphilis by means of Wassermann's test, do not appear sufficiently regularly in the serum of tuberculous patients to admit of their being applied to the diagnosis of this disease. The same applies to the precipitin test, which for a time was advocated by some of the Italian observers. Recently Izar and Ascoli (22) have attempted to apply the meiostagmin reaction to the diagnosis of pulmonary tuberculosis. The reaction consists in the reduction of surface tension which results when a serum containing antibodies and an antigen are mixed in certain proportions. The reduction of surface tension is measured by the stalagmometer of Traube. This test has not been sufficiently investigated in tuberculosis for an opinion to be expressed on its merits.

Under the heading of serum reactions comes the now familiar opsonic test devised by Sir Almroth Wright. The technique for the estimation of the opsonic index has been so often described that it need not be detailed here. It is, however, well to insist upon the advisability of conducting the whole experiment with blood the origin of which at the time in any particular case is unknown. All tests made in this hospital laboratory have been performed in this way so as to eliminate the factor of personal bias. The original work of Wright and his collaborators, and the searching experiments of Bulloch, showed that the indices of apparently healthy individuals remained constantly within certain limits. These limits have been fixed as lying between 1·20 and 0·80 on either side of unity. In the experiments in which I have been engaged for four years, the bloods of two apparently healthy individuals have been included as controls, and unless these have coincided well within the above-mentioned limits, the whole number of indices in that experiment have been discarded. The uniformity of the indices of the same control individuals, estimated almost daily over periods of months, bears testimony to the constancy of the normal limits. The technique is laborious in the extreme, but with due care can be made very accurate.

In the original experiments of Wright—which were amply confirmed by Bulloch—it was found that the characteristic opsonic index of a localised chronic tuberculous infection was low. The charts published in Sir Almroth Wright's

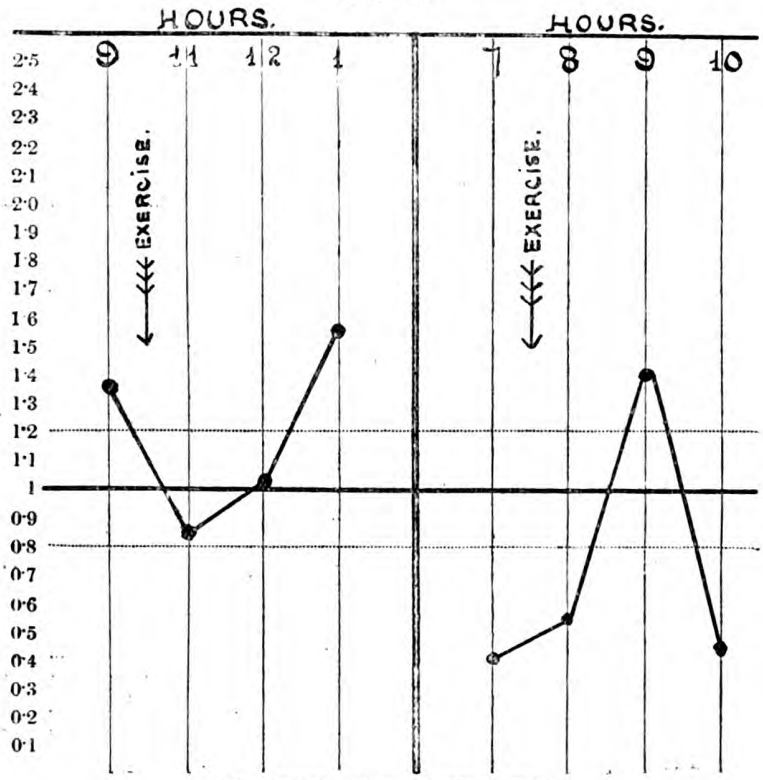
"Studies in Immunisation" (23) illustrating the effects of massage and passive congestion (Bier's hyperæmia) practised on localised tuberculous lesions, show that a rise of the opsonic index usually follows such a procedure. In dealing with a generalised infection such as active, advanced pulmonary tuberculosis, the conditions are different. The opsonic indices no longer remain low, but continuously show fluctuations above and below the normal line. If in cases of active, afebrile pulmonary tuberculosis the amount of movement indulged in by the patient is strictly supervised, it has been shown (24) that the opsonic index can be continuously maintained at a high level. If such variations from the normal occur in tuberculous, as opposed to healthy individuals, the opsonic index should prove of value in the

CHART 2.



Opsonic index (thick broken line) and temperature (thin continuous line) before and after employment of ophthalmo-reaction. C + + denotes that the reaction was marked.

CHART 3.



Opsonic index before and after exercise.

diagnosis of the disease. It would be convenient if one single examination of the opsonic index sufficed to make a diagnosis. Unfortunately this is far from being the case. An analysis of 200 single opsonic indices taken at random, estimated on patients all of them suffering from pulmonary tuberculosis, with tubercle bacilli in their sputum, shows that 99 were outside the limits of 1·20 and 0·80, whilst 101 were within the normal. Unless the opsonic index falls well outside the normal limits no deductions should be drawn from a single observation.

Wolff and Reiter (25) found in 64 cases of tuberculosis that the opsonic index both on single examination and several examinations was low in 62 per cent. and 57 per cent. respectively. The index was raised on single examination in 25 per cent., on numerous examinations in 12 per cent. The index was never within normal limits after numerous examinations. With single examinations it was within normal limits in 8 cases, 12 per cent. Kössler and Neumann (26) found that afebrile early cases of pulmonary tuberculosis had nearly always a low opsonic index, whilst the febrile ones had a raised index.

For purposes of diagnosis at this hospital the blood is examined before and after walking exercise, the latter being in no way controlled by myself. The amount of exercise performed may be insufficient to activate the serum, but in the event of a negative index being returned the physician alone must determine whether a second estimation after increased exercise is advisable. This essential reservation was evidenced by the research at the Frimley Sanatorium. For instance, a patient who showed no fluctuation when performing Grade 2 showed a marked variation when performing the labour of Grade 3.

Reviewing as a whole the positive results of examinations of the opsonic index made with a view to diagnosis, the following four types of variation can be defined: A. An index low before, but rising after exercise. B. An index low before and after exercise (? insufficient exercise). C. An index high before and falling after exercise. D. An index high before and after exercise.

Taking 250 consecutive cases of doubtful pulmonary tuberculosis in which the tuberculo-opsonic index was estimated before and after exercise for diagnostic purposes—

The index remained within normal limits in 91 cases.
The index started low and rose after exercise in 56 cases.
The index started low and remained low after exercise in 41 cases.
The index started high and fell after exercise in 54 cases.
The index started high and remained high after exercise in 8 cases.

So that we have this, to my mind, very striking result:—

Of 159 in which the index varied outside normal limits:

97 started low, and of these { 56 rose as the result of exercise. / 41 remained low after exercise.

62 started high, and of these { 54 fell after exercise. / 8 remained high.

By examining four specimens of blood—the first being taken at rest, the second immediately after exercise, and two more during subsequent rest—it was found that the positive curves conformed in the majority of cases to two types. Those whose index was high in the morning before exercise gave a curve with the apex downwards as the result of exercise, whilst those with an index starting low in the morning made a curve with the apex pointing upwards as the result of exercise. (Chart 3.)

I would suggest that the group A and B point to a localised chronic tuberculous infection, which, however, calls for treatment and must still be regarded as active. It must be remembered that the clinically arrested cases at the Frimley Sanatorium (*loc. cit.*) showed indices which remained within normal limits before and after the hardest labour. The high indices of Group C and D may be regarded as significant of greater activity of disease in that they imply an increase in the elaboration of protective substances in the serum.

It is a matter of extreme difficulty to prove whether or no the doubtful cases giving a positive index are suffering from active tuberculosis. In 100 cases with a positive index and no tubercle bacilli in the sputum special care was taken to find tubercle bacilli at a date subsequent to the blood examination. In 14 cases tubercle bacilli were found, confirming the diagnosis. The following table, which appears in the Medical Report of the Brompton Hospital, 1909, embodies the results of the opsonic index test in 58 cases.

Opsonic Index in 68 Cases.

* This includes cases which gave a history of hæmoptysis, or which had pyrexia or other symptoms suggesting a tuberculous condition. Of the negative cases, one had tubercle bacilli in the sputum, one reacted to tuberculin, one gave a positive ophthalmic reaction, and the fourth von Pirquet's test.

† Physical signs of quiescent pulmonary tuberculosis present.

The following list comprises 100 cases, selected by the physicians, in which recourse to the tuberculo-opsonic index was considered necessary owing to ambiguity of the clinical evidence. It will serve as an illustration of the possible application of this test to some of the problems of pulmonary tuberculosis. The letters A, B, C, and D, after positive reactions, refer to the four types of variation in the opsonic index referred to above.

Physician's Note.	*Opsonic Index Test.*
1. No abnormal physical signs. No tubercle bacilli in sputum	Positive (C).
2. A doubtful tuberculous case. Slight impairment at right apex; no adventitious sounds; no sputum	,, (A).
3. Early physical signs at left apex. No tubercle bacilli in sputum	Negative.
4. No tubercle bacilli found. History of pleurisy ...	,,
5. ? Pulmonary tuberculosis; physical signs most indefinite	Positive (A)
6. Definite signs at left apex (early). No tubercle bacilli (three examinations). Opsonic indices normal	Negative.
7. Very slight signs. Calmette reaction +. No tubercle bacilli	,,
8. No tubercle bacilli (three times). Calmette reaction negative once	Positive (A).
9. Pleural thickening and induration of lung following pneumonia. Probably pulmonary tuberculosis. Tubercle bacilli present when out-patient long time ago	Negative.
10. No tubercle bacilli found. Physical signs indefinite. History of hæmoptysis	,,
11. No tubercle bacilli. Apical consolidation	,,
12. Family history of tuberculosis; history of hæmoptysis. No sputum	,,
13. No sputum. Indefinite signs; normal temperature. Sent in as early tubercle	,,
14. Doubtful physical signs	Positive (B).
15. Hæmoptysis five months ago. No physical signs of disease	Negative.
16. Physical signs, but no tubercle bacilli	Positive (D).
17. No adventitious sounds. No sputum; hæmoptysis	,, (C).
18. Doubtful signs of consolidation at left apex. No sputum	Negative.
19. No tubercle bacilli present. Chronic bronchitis with pigeon breast	,,
20. Bronchiectasis (apical cavity). No tubercle bacilli in sputum	,,
21. No sputum. Very slight impairment of resonance at right apex	,,

	Physician's Note.	*Opsonic Index Test.*
22.	Impaired resonance at left apex. No adventitious sounds	Positive (A).
23.	A contact case with doubtful physical signs	,, (1).
24.	Case of chronic pneumonia (apical). No tubercle bacilli	Negative.
25.	Quiescent disease, both apices. No sputum...	,,
26.	Quiescent disease, both apices. No sputum	,,
27.	No tubercle bacilli found on many examinations. History of hæmoptysis 16 years ago	,,
28.	No tubercle bacilli found, but clinically C.P.T.	Positive (A).
29.	Cutaneous (von Pirquet) reaction negative. Age 27	Negative.
30.	No tubercle bacilli. Signs indefinite	Positive (B).
31.	No tubercle bacilli found, but clinically C.P.T.	,, (A).
32.	Doubtful impairment of resonance over right clavicle; no adventitious sounds; no tubercle bacilli	Negative.
33.	Slight dulness at left apex; heart drawn up. No adventitious sounds. No sputum...	Positive (C).
34.	No physical signs. Doubtful case	Negative.
35.	Old pleurisy	Positive (A).
36.	No sputum available. Physical signs at left base	Negative.
37.	No sputum; many signs	Positive (C).
38.	Signs, but no tubercle bacilli	,, (1).
39.	Thickened pleura—? tuberculous. No sputum	,, (A).
40.	No tubercle bacilli found. History of hæmoptysis	,, (C).
41.	No sputum. No active physical signs	Negative.
42.	Sibilant signs, chiefly at apices	,,
43.	Early signs of consolidation, right upper lobe and middle lobe. No tubercle bacilli	Positive (A).
44.	Apparently tuberculosis of larynx, but no tubercle bacilli. No von Pirquet reaction; Calmette reaction doubtful	,, (C).
45.	Case of persistently low temperature with history of hæmoptysis 14 months ago	,, (B).
46.	Physical signs very doubtful, but probably pulmonary tuberculosis	,, (D).
47.	Case of morbus cordis with signs in lungs. No tubercle bacilli	,, (1).
48.	No tubercle bacilli. Negative Calmette reaction. No definite signs, but history of chronic cough and blood-stained expectoration	Negative.
49.	No sputum. Calmette reaction negative. Signs indefinite	,,
50.	No sputum. Negative Calmette reaction. No definite signs. Treated for "consumption" for five years	,,
51.	Physical signs present, but tubercle bacilli absent	Positive (C).
52.	No tubercle bacilli. Doubtful signs	Negative.
53.	Signs very slight. Has nursed mother for two years who died from pulmonary tuberculosis	Positive (B).
54.	No sputum. Slight impairment of resonance at right apex, with prolonged expiration	,, (B).
55.	Chest apparently healthy, but impairment at both apices and crepitations noted in out-patient department six months ago	Negative.
56.	No tubercle bacilli (three times). Very slight physical signs	,,
57.	Signs of apex consolidation; no adventitious sounds. No tubercle bacilli (three examinations)	Positive (A).
58.	Probably pulmonary tuberculosis. Slight signs. No tubercle bacilli (very little sputum)	,, (C).
59.	Asthma; very slightly impaired note at right apex. ? pulmonary tuberculosis. No sputum	Negative.
60.	Probably bronchiectasis, but ? pulmonary tuberculosis. No tubercle bacilli in sputum	,,
61.	No sputum. Calmette test negative (twice), but opsonic indices already done were positive	Positive (A). Negative.
62.	No physical signs	Positive (C).
63.	Case of mitral stenosis tested with Calmette reaction as control; distinct reaction second time of testing	,, (C).
64.	Probably tubercle. No tubercle bacilli found yet; Calmette test twice negative	,, (C).
65.	Fairly obvious signs at apices. No tubercle bacilli (three times)	,, (D).
66.	Sent in as tuberculous. No physical signs except sibilant râles, and expiration and vocal resonance a little exaggerated at right apex	Negative.
67.	? Basal phthisis ? Bronchiectasis	Positive (1).
68.	Acute pulmonary tuberculosis	,, (C).
69.	No tubercle bacilli. Slight physical signs	,, (D).
70.	Chronic bronchial catarrh, with ? pulmonary tuberculosis. No tubercle bacilli found, but history of slight hæmoptysis	,, (A).
71.	Physical signs, but no tubercle bacilli found	,, (B).
72.	History of hæmoptysis, but tubercle bacilli absent both this year and last. Normal temperature throughout	Negative.
73.	Basic crepitations (both bases). No tubercle bacilli	Positive (C).
74.	Doubtful physical signs of disease. No tubercle bacilli. Previous opsonic test positive	Negative.
75.	No tubercle bacilli found. No definite signs. Family history of tuberculosis	,,
76.	No tubercle bacilli found. Ophthalmo-reaction positive. Physical signs negative	Negative.
77.	No tubercle bacilli found. Symptoms of bronchial asthma, but coloured sputum. Family history of tuberculosis	,,
78.	Family history of tuberculosis. No definite signs. No sputum	Negative.
79.	Signs of old consolidation at both apices; no adventitious sounds	,,
80.	No tubercle bacilli. Physical signs present	Positive (A).
81.	? If any physical signs of disease (doubtful at right apex)	,, (C).
82.	Emphysema with old disease, probably both apices	,, (A).
83.	Slight hæmoptysis seven months ago. No adventitious sounds. No tubercle bacilli found	Negative.
84.	Quiescent pulmonary tuberculosis. No sputum...	Positive (A).
85.	Probably caries of the bodies of third to seventh dorsal vertebræ	,, (A).
86.	The opsonic test is negative, but we should expect positive	,, (1)
87.	Probably caseous pneumonia	,, (A).
88.	Tuberculous pleurisy	,, (*)
89.	Consolidation of right apex. No râles. No sputum. Pneumonia, right side, ten weeks ago, but right lung is contracted	,, (1)
90.	Slight physical signs of impairment of both apices and left base without adventitious sounds	Negative.
91.	Quiescent disease of both apices	,,
92.	? Arrested tubercle	Positive (B).
93.	? Arrest (how far?)	Negative.
94.	To decide whether patient's tubercle is arrested	Positive (C).
95.	How near arrest?	,, (C).
96.	? Arrest	Negative.
97.	Doubtful case. Hæmoptysis *v.* hæmatemesis	,,
98.	Old pulmonary tuberculosis. Quiescent. ? arrested	,,
99.	Broncho-pneumonia after measles. ? pulmonary tuberculosis. ? bronchiectasis	Positive (C).
100.	? active tubercle	,, (C).
		,, (D).

(*) Swinging index whilst in bed. (1) A single estimation.

Summary.

1. In the diagnosis of early pulmonary tuberculosis the recent methods of concentration (antiformin) should always be employed for the exposition of tubercle bacilli in the sputum and fæces.

2. The difficulty of interpreting the results of the various tuberculin tests seriously limits their value in the diagnosis of active pulmonary tuberculosis.

3. A positive opsonic index test is of undoubted value in the diagnosis of active pulmonary tuberculosis. A negative opsonic index test must be taken with reserve. The interpretation of the result rests with the clinician, who can take into consideration all the additional factors in the diagnosis of the case.

Brompton Hospital for Consumption.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.

—The autumn dinner of the southern branch of the Durham University Medical Graduates' Association was held on Dec. 2nd at the Criterion Restaurant, when many members and guests were present. Dr. J. Inglis Parsons, vice-president of the association, occupied the chair. The toast of the "University and Association," proposed by Sir W. H. Allchin, was acknowledged by Dr. William Rawes, and that of the visitors by Mr. Charters J. Symonds. Dr. W. Davis made a delightful speech in proposing the vice-president's health. Excellent music was provided by Mr. John W. Ivimey.

NOTE ON TUBERCULOUS MENINGITIS,

WITH ESPECIAL REFERENCE TO THE INVASION SYMPTOMS WHEN THE DISEASE OCCURS IN ADULTS.

BY W. B. WARRINGTON, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN TO THE NORTHERN HOSPITAL AND TO THE EYE AND EAR INFIRMARY, LIVERPOOL; LECTURER IN CLINICAL MEDICINE IN THE UNIVERSITY.

TUBERCULAR meningitis in adults is met with chiefly as a terminal event in chronic pulmonary phthisis. Its frequency in this condition has been variously estimated. Dr. S. West[1] says it accounts for 8 per cent. of deaths, but the figures he gives from an analysis of his own fatal cases—viz., 1·5 per cent. when this lesion was present alone with the disease in the lungs, or 2·5 per cent. if cases of generalised tuberculosis are included—agree better with what appears to be the general experience. Thus, of 531 fatal cases at the Brompton Hospital, Fowler and Godlee[2] state that tubercular meningitis was the cause of death in 3·3 per cent.

Several writers mention that when tubercular meningitis occurs in adults the clinical picture may present unexpected features, misleading if the possibility of this condition is not remembered. Professor Oppenheim,[3] in describing the early delirium and mental confusion which soon occur, points out that grown-up patients may go about in this stage and appear as if afflicted mentally; sometimes they are in a dreamy state, sometimes excited and agitated, so much so as to closely resemble persons under the influence of alcohol.

Sir William Gowers[4] says that in this stage young women may show hysteroid symptoms, and in the "System of Medicine" of Professor Osler and Professor McCrae Dr. Lawrason Brown[5] writes: "In certain instances there has been great difficulty in making the diagnosis from hysteria, early mental disease, or delirium tremens." A further point to be noticed is that this complication has often occurred in those in whom the pulmonary disease appeared to be making satisfactory progress. This has been alluded to by Sir R. Douglas Powell[6] and Sherman G. Bonney.[7]

During the last few years I have met with several cases of this disease in adults in which anomalous symptoms of this kind were observed, and, followed as they were by somewhat sudden coma and death, formed a striking clinical picture. I related these cases at the meeting of the Association of British Physicians held in Liverpool this year, and the short discussion which followed leads me to hope they are sufficiently interesting to be placed on record.

CASE 1.—The patient, a man aged 33 years, was fairly well developed, and without any history of important antecedent illnesses. He kept a small grocer's shop in the north end of Liverpool, where the recent religious riots occurred; the disturbance appears to have greatly upset him, and it was to this that he attributed the vague pains in the head, general weakness, insomnia, and dyspeptic symptoms with some vomiting for which a month before his death he first consulted a medical man. He continued, however, to attend to his business for over a fortnight. To relieve the sleeplessness he was given on the night of Dec. 5th a largish dose of chloral and bromide. On awakening in the morning he drank a cup of tea, said a few words, and settled down to sleep. Consciousness was never recovered.

On Dec. 7th I first saw the patient. The temperature was slightly raised; pulse of 68, and respirations 24 a minute. There were no signs of paralysis; ophthalmoscopic examination was normal. The viscera appeared healthy. I found a slight degree of Kernig's sign, and some little rigidity of the neck. Examination of the cerebro-spinal fluid showed that this was under considerable pressure; it was quite clear, and contained a large number of lymphocytes. Death took place on the 11th, without the development of any further symptoms. The temperature ranged from 100° to 101° F., the pulse and respirations gradually increasing in frequency.

Permission for a post-mortem examination limited to the head was obtained. The typical appearances of tuberculous meningitis were found, the vessels of the base of the brain and along the Sylvian fissure being studded with innumerable tubercles.

CASE 2.—The patient, a man aged 38 years, was admitted to hospital on June 9th, 1905. He had been out of work for some months, had lost weight, and suffered from mental depression. The symptoms of his fatal illness began five weeks before admission with feeling of numbness in the right shoulder; this sensation spread down the arm and then invaded the lower limb. During the next month the sensations recurred with great frequency, and at last were accompanied by temporary loss of power. On admission to hospital the patient looked ill, but was quite rational and able to walk. The temperature was slightly raised to 100° or 101° F., the pulse was 94, and respirations 28. No disease was found in the thoracic or abdominal viscera, and ophthalmoscopic examination showed a healthy fundus. Headache and vomiting were absent, but percussion of the skull was somewhat painful. There were no paralyses or alterations in the reflexes. The patient remained in this condition for ten days, when quite suddenly he became mildly delirious and passed into a state of semi-coma. A right hemiplegia was now present with the extensor plantar response. By lumbar puncture a fluid was obtained containing an excess of albumin and a large number of cells both of the polynuclear form and lymphocytes. He never recovered consciousness, and at the end of a week the temperature rapidly ran up and death occurred.

Unfortunately here again the head only could be examined. The brain showed the characteristic appearance of tuberculous meningitis, and this was confirmed by microscopical examination.

CASE 3.—The patient, a woman, aged 45 years, had suffered from phthisis for ten years, but had been in fair general health, able to do her household and other work. There was no cough or other symptom of the disease. Examination of the lung showed the presence of a large dry cavity. About a month before her fatal illness throbbing sensations in the head and vague pains began to trouble her; these symptoms disappeared for a time, but afterwards returned in greater severity. At the end of a fortnight the patient was compelled to go to bed and became somewhat apathetic. The temperature was a little raised, varying from 99° to 101° F. As the drowsiness increased the pain disappeared. When seen by me the patient was very weak and drowsy, but could be roused to answer questions. There was slight optic neuritis, but no other signs of nervous disease. Kernig's sign and rigidity of the neck muscles were absent. The cerebro-spinal fluid was clear, highly albuminous, and contained a large excess of lymphocytes.

CASE 4.—The patient, a man, aged 33 years, was under the care of Dr. John Owen, who has kindly given me the notes. The man was a labourer, and previous to this illness appears to have been in good health; he said that he had never lost a day's work. About one month before his death his fellow-workmen are said to have noticed that he was quieter than usual, but only a fortnight before the end were there any definite symptoms—viz., headache and vomiting. He complained to his friends of weakness and was seen to tremble and stagger. It was, however, not until three days before his death that he was compelled to remain in bed and send for a medical man. He was then found to be in a stuporous condition. On the next day he was seen by Dr. Owen, who found no physical signs of disease, with the exception of an extensor plantar reflex on one side. There was no Kernig's sign, no head retraction, nuchal rigidity, or optic neuritis. By lumbar puncture a fluid was obtained which showed the usual characteristic, excess of lymphocytes, and also the tubercle bacilli.

CASE 5.—The patient, a woman, aged 26 years, had suffered from headache for about a year, but had continued her household duties and other work. On April 22nd, 1910, she was seen by Dr. E. I. Claxton, who found her excited and hysterical in manner. She had vomited several times and complained of pains in the back and head. The pulse and temperature were normal. Dr. Claxton carefully examined the nervous system, but found no objective signs of disease. The vomiting ceased, but the mental condition remained one of great excitement, the patient raving, moaning, and tossing about. On April 30th paralysis of the left abducens was first observed, and the diagnosis of organic disease, hitherto uncertain, being now obvious, she was sent by Dr. Claxton into hospital, where she was admitted in a condition of exhaustion and incoherent delirium. The patient was obviously very ill; the skin dry, the tongue furred, cracked, and dry, and the breath foul; the temperature was 100° F., and the pulse 76. Paralysis of the left external rectus muscle was present and a slight Kernig's sign, but no other physical signs. The diagnosis of meningitis was made, probably tuberculous, and this was confirmed by lumbar puncture, the fluid containing a large number of lymphocytes and tubercle bacilli. The patient lived nine days, the delirium being gradually replaced by drowsiness and coma.

The post-mortem examination showed obsolete tuberculosis of the apex of the left lung, caseating bronchial glands, a caseous solitary tubercle in the vermis cerebelli, and generalised tuberculous meningitis of the usual distribution.

Of these five cases all were engaged in their usual occupation before the fatal illness, and previous disease was known to exist in only one—viz., the woman with chronic phthisis. In all there was an incubation period of three to four weeks, characterised by slight physical and mental symptoms of depression, strangeness in manner, or hysteroid attacks; then a sudden change, a rapid onset of coma terminating within a week in death, the terminal stage also being, with the exception of Case 5, unaccompanied by obtrusive physical signs.

In a recent paper J. Jaquet,[8] writing on this subject, says that of 204 fatal cases of chronic phthisis 16 died from tuberculous meningitis as proved by necropsy, and of these cases seven were between the ages of 41 to 68. Clinically, several of these cases presented the same startling development of symptoms, and most had been about their usual work until the onset. Two patients were brought into the hospital unconscious, in which state they had been found in the streets; one was seen to stagger about as if drunk; another, who complained of headache, was morose and silent; and another, taken ill whilst in the hospital, showed as the first symptoms restlessness and attempts to get out of bed. This invasion stage lasted a week or more, followed by the terminal stage of coma, the average duration of which was ten days. There were

throughout very few physical signs and no definite paralyses. Vomiting was absent in all, and headache only a prominent symptom in two instances.

Diagnosis.—When a patient known to have chronic phthisis begins to show anomalous mental symptoms, invasion of the meninges may be suspected, and this suspicion increases if headache and other symptoms, especially the appearance of the Babinski reflex or a difference in the knee-jerks, are present. When, however, previous disease is not known and evidence of disease elsewhere cannot be found the opening symptoms are very difficult to correctly interpret. This must have been so especially in my first two cases. If the symptoms are sufficiently serious it appears that the examination of the cerebro-spinal fluid will usually clear up the diagnosis.

My object has been to call attention to the manner in which tuberculous meningitis sometimes develops in adults. I should also like to take this opportunity of mentioning two other cases of this disease of some interest.

1. An instance of recovery. Dr. Alfred E. Martin[9] has fully reviewed what is known of the remissions and recovery in tuberculous meningitis.

CASE 6.—My case is that of a boy, aged 11 (seen a year ago under the care of Dr. Bennett Jones), who presented the usual characteristic manifestations and double optic neuritis. The cerebro-spinal fluid contained many cells, both polynuclear and lymphocytes; tubercle bacilli were found on a number of occasions. After a prolonged illness the patient gradually recovered. His general health is now excellent; he plays games and does the ordinary work of a school-boy. There is, however, a slight right monoplegia of the arm.

2. An instance of meningo-encephalitis tuberculosa circumscripta, the meningitis *en plaque* of the French writers:—

CASE 7.—The patient, a man aged 35 years, was admitted to hospital on March 10th, 1909. He was extremely ill and greatly emaciated, somewhat cyanosed, and suffering from dyspnœa. He appears to have been at his work until three weeks before this illness; ten days before admission he was seized with feverish symptoms and pains in the back and abdomen. On the next day the right hand was weak, and on the day following he was unable to speak. The loss was permanent; the only word he was known to say was "Sammy," the name of his child. A few days later several convulsions occurred. Almost up to the time of his admission, however, he appears to have been able to stand. On examination we found that the patient was conscious and responded to pantomimic suggestion. The whole of the right upper limb was completely paralysed, and there was considerable paresis of the right lower face. He was able to move both lower limbs. The knee-jerks were present and the plantar responses were of the flexor type. Examination of the lungs gave evidence of general bronchitic signs. The patient died in a few days. The diagnosis was considered to be acute general tuberculosis.

The post-mortem examination disclosed miliary tuberculosis of the lungs and old lesions at both apices. On the surface of the left hemisphere of the brain two plaques of disease were seen at the sites indicated in the figure. The one in the temporo-sphenoid convolution was hard and opaque white; the larger one in the angular gyrus was partly dull red, the colour evidently due to subjacent hæmorrhage, and

Meningo-encephalitis tuberculosa circumscripta.

partly covered with pus. There was no generalised meningitis or tubercle along with the course of the vessels.

Horizontal sections were cut through the brain at the level of the points *a*, *b*, *c*, *d*. Those through *a* and *b* showed that the discolouration was due to the presence immediately between the cortex of two plum-coloured masses of hæmorrhagic brain tissue, and that the tissue beneath these was necrotic. Softening without hæmorrhage was found in the sections at the levels *c* and *d*. The cerebro-spinal fluid was somewhat turbid.

[9] Brain, vol. xxxii., p. 209.

This condition is not very common. An excellent description, with references to the findings of other writers, is given by Oppenheim in his Lehrbuch,[10] and it is noteworthy that six cases recovered in which he diagnosed this condition.

The hæmorrhage is doubtless due to tuberculous vascular disease, and it is a point of some practical interest that the fluid obtained by lumbar puncture in tuberculous meningitis is sometimes coloured with blood. I have on the post-mortem table found in several instances considerable meningeal hæmorrhage.

Liverpool.

THE ETIOLOGY OF BERI-BERI.

BY HENRY FRASER, M.D. ABERD.,

DIRECTOR, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR, FEDERATED MALAY STATES;

AND

A. T. STANTON, M.D. TOR.,

BACTERIOLOGIST, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR.

IN a former paper published in THE LANCET[1] it was shown that the occurrence of beri-beri was intimately associated with the consumption of a diet of which white rice was the staple. This view of the origin of the disease, first stated in concise form in this country by Braddon,[2] had its beginnings in the work of the Dutch physicians of the last century, and has since been amplified and confirmed by the labours of Van Dieren, Dubruel, Fletcher, and others, and more especially by the valuable observations and researches of Braddon.

Further experimentation was undertaken by us to determine the mode of operation by which white rice was able to produce this result. Braddon believed that the cause of beri-beri was a poison developed in stale white rice by the action of some organism, while Dubruel held that a living germ was ingested with white rice, and that this germ, multiplying in the body, produced the disease. The observations made by us led to the conclusion that beri-beri is a disorder of metabolism, and that white (polished) rice, as milled by machinery on a large scale, commonly makes default in respect of some substance or substances essential for the maintenance of the normal metabolism of nerve tissues. It was further shown that in the original grain these substances are contained in the cells of the subpericarpal layers which are removed in the process of polishing. As measures for the prevention of the disease it was recommended that, for the ordinary white rice in the diet, there should be substituted a rice in which the polishing process had been omitted or carried out to a minimal extent. These conclusions, first published in December, 1909, received the endorsement of the Far Eastern Association of Tropical Medicine at its meeting in Manila in March, 1910,[3] and practical measures, based upon them, are now being taken by the Governments of those countries where beri-beri most abounds.

During the past year attention has been directed towards the determination of the nature of the substances present in the subpericarpal layers of the original grain which are removed in the milling process and which, it would appear, are of such high physiological importance in maintaining normal nutrition when a diet largely composed of white polished rice is consumed. This research has not yet been completed, but thus far it has confirmed the accuracy of the work already recorded, and by a process of exclusion the problem has become appreciably less complex.

Introductory.

For the purpose of testing the value of the various materials, fowls weighing 1200 grammes or thereabouts were employed. Each, as in previous experiments, was confined in a separate cage and, save in one instance, groups of 12 were used. The fowls received rice twice daily at 10 A.M. and 3 P.M., and when receiving polishings or materials prepared from polishings, the substance in question

[10] Vol. ii., p. 896.

[2] W. L. Braddon: The Etiology of Beri-beri, Federated Malay States Medical Archives, 1901.

[3] Transactions of the Far Eastern Association of Tropical Medicine, Philippine Journal of Science, 1910, vol. v., No. 1.

was given as an emulsion, by means of a stomach-tube, half an hour after the rice had been given. Every fowl was weighed once a week at 12 noon.

As a result of a series of former observations it had been determined that fowls weighing from 1200–1400 grammes required about 60 grammes of unpolished rice daily, and, if fed on 60 grammes polished rice, they required in addition 5 grammes of sifted polishings for the maintenance of weight and health. In a previous experiment, where products derived from different lots of padi were employed, 3·5 grammes of the polishings were shown to be sufficient with the white rice then in use. In the present experiment all the products employed—unpolished rice, polished rice, polishings, &c.—were derived from the same lot of padi. For purposes of comparison the following results of analyses are given:—

—	Protein.	Fats.	Carbo-hydrates.	Ash.	Moisture.	P_2O_5
	%	%	%	%	%	%
Polishings (sifted)	13·7	14·16	52·77	7·54	11·83	4·1
Unpolished rice ...	9·0	1·65	75·52	1·08	12·75	0·56
Polished rice... ...	8·6	0·22	76·23	0·6	14·35	0·26

When the composition of these articles is calculated on dried materials the differences are rendered more striking and accurate, and when in a similar manner the composition of a diet made up of 60 grammes of polished rice and 5 grammes of polishings is calculated it will be seen how closely such a diet approximates to one of unpolished rice.

Calculated on Dried Materials.

—	Protein.	Fats.	Carbo-hydrates.	Ash.	P_2O_5
	%	%	%	%	%
Polishings (sifted)	15·5	16·0	59·8	8·5	4·65
Unpolished rice	10·3	1·89	86·5	1·23	0·64
Polished rice	10·0	0·25	89·0	0·7	0·3
Ration 60 grammes polished rice *plus* 5 grammes polishings contains per cent.	10·4	1·5	86·6	1·31	0·64

Sifted polishings were invariably employed because polishings as received from the millers contain a considerable mixture of husk and broken rice.

Polishings when fresh are neutral in reaction, but on keeping they become acid. This change does not impair their efficiency, however, and polishings which have been stored with ordinary care for months are quite as valuable as the fresh materials. The ordinary process of cooking does not impair the value of polishings. For these reasons it is considered that the essential substance or substances are not unstable.

1. *Fat.*—Fat in the rice-grain is mostly confined to the subpericarpal layers. Unpolished rice is therefore richer in fat than polished rice, and polishings are very rich in fat. To determine the value of this fat a quantity of sifted polishings was packed in a percolator and percolated with petroleum ether. In this way the amount of fat in the polishings was reduced from 14·16 to 0·6 per cent. The fat-free polishings were dried by exposure to the sun until free from petroleum ether.

Twelve fowls were fed on polished rice and received in addition daily 4·5 grammes of fat-free polishings, being the approximate equivalent of 5 grammes of sifted polishings. The fowls remained healthy and maintained their weight just as had been the case when fowls received polished rice and sifted polishings. The non-importance of fat was therefore decided and its exclusion from the number of possibilities was of the utmost value since the fat had hitherto complicated our experiments.

2. *Phytin.*—Estimations of the percentage of phosphorus pentoxide in rices had consistently shown their value as indicators of the liability or otherwise of a given rice to produce polyneuritis. Thus the higher the percentage of phosphorus pentoxide contained in a rice, the less liable was that rice to produce polyneuritis when fowls were fed on it.

The unpolished rice, which we employed, contained 0·56 per cent. phosphorus pentoxide and did not cause polyneuritis. The polished rice contained 0·26 per cent. phosphorus pentoxide and invariably caused polyneuritis, while washed polished rice containing 0·22 per cent. phosphorus pentoxide was more harmful than the unwashed polished rice. This suggested the probability that the essential substance was one containing phosphorus. It was first stated by Dr. Hans Aron,[4] Bureau of Science, Manila, that the substance in question is phytin, the calcium magnesium salt of an organic acid containing phosphorus. We estimated that the unpolished rice in use contained 1·07 per cent. of phytin, that the polished rice contained only a trace of that salt, and that the polished rice after washing and drying contained none. The sifted polishings contain 8·8 per cent. of phytin.

In testing the importance or otherwise of phytin we did not employ the commercial product because of our ignorance of its source and method of preparation, but prepared it ourselves in the following manner. Sifted polishings were mixed with 0·3 per cent. hydrochloric acid in the proportion of 300 grammes of the former to 2000 cubic centimetres of the latter, the mixture was stirred throughout the day, and on the following morning was filtered through a Buchner's filter. The clear yellowish filtrate was mixed with one and a half times its volume of 95 per cent. alcohol, which produced a white precipitate of phytin; the mixture was allowed to stand for a few days. The precipitate was collected, washed with strong alcohol to free it from acid, and dried in a vacuum desiccator. A friable cake of phytin was obtained readily reducible to a white powder, soluble in water, yielding an opalescent solution with an acid reaction and giving, on addition of sodium carbonate, a white flocculent precipitate. The powder contained 34 per cent. of phosphorus pentoxide.

A fowl consuming 60 grammes of unpolished rice daily would be receiving 0·66 gramme of phytin, and a fowl receiving the same amount of washed, polished, and therefore phytin-free, rice would require to have in addition that amount of phytin daily in order to bring the value of this diet, in respect of phytin, up to that of an unpolished rice diet.

Twelve fowls received washed, polished rice, and in addition phytin, which was given in the following manner: 9 grammes of phytin were dissolved in distilled water, the solution neutralised with sodium carbonate, and the volume made up to 360 cubic centimetres. Each fowl received 15 cubic centimetres of this suspension at 10.30 A.M. and 3.30 P.M. daily, an amount of phytin slightly in excess of the estimated quantity. All the fowls lost weight and cases of polyneuritis occurred just as if the fowls had received washed, polished rice only.

In the next experiment 12 fowls received the phytin-suspension intimately mixed with the washed, polished rice, but the results were the same, and the importance of phytin was by these experiments definitely disproved.

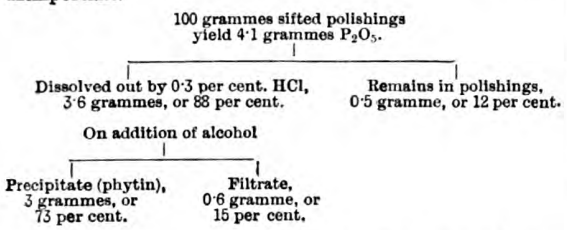
3. *Substances soluble in 0·3 per cent. hydrochloric acid.*—Experiments were next carried out to determine if, when polishings are macerated in 0·3 per cent. hydrochloric acid, the essential substance or substances pass into solution. This solvent was chosen as it had been employed for the extraction of phytin. Polishings in quantities of 180 grammes, being the amount required by 12 fowls in three days, were mixed with 1000 cubic centimetres of 0·3 per cent. hydrochloric acid, stirred during the day, and the following morning filtered through a Buchner's filter. 100 cubic centimetres of 0·3 per cent. hydrochloric acid were used to wash out the vessels. When fluid could no longer be extracted from the mass it was mixed with 600 cubic centimetres of 0·3 per cent. hydrochloric acid, stirred during two hours, and thereafter filtered as before. The extracted polishings were mixed with distilled water, nearly neutralised with sodium carbonate, and the volume was adjusted to 1080 cubic centimetres. 30 cubic centimetres of this emulsion contained 5 grammes of polishings, less the materials dissolved out by the acidulated water. The combined

[4] Hans Aron: Philippine Journal of Science, 1910, vol. i., p. 97.

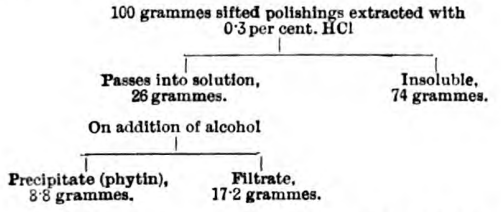
filtrates obtained from 180 grammes of polishings were nearly neutralised with sodium carbonate and concentrated at a low temperature to a volume of 1080 cubic centimetres. 30 cubic centimetres of this suspension contained the substances dissolved out by acidulated water from 5 grammes of polishings.

Twelve fowls were fed on washed, polished rice, each receiving daily 30 cubic centimetres of the emulsion of extracted polishings; cases of polyneuritis occurred.

Twelve fowls were fed on washed, polished rice, each receiving in addition 30 cubic centimetres of the suspension of dissolved substances; cases of polyneuritis did not occur. Therefore the essential material was removed and uninjured by the process of extraction and subsequent treatment. By this process of extraction 88 per cent. of the phosphorus pentoxide contained in polishings is dissolved out. Of this amount, 73 per cent. is represented by the phytin in the solution, so that, together with the 12 per cent. remaining in the polishings after extraction, 85 per cent. of the phosphorus pentoxide contained in polishings is shown to be unimportant.



4. *Alcohol (proof spirit) soluble fraction of the substances originally soluble in 0·3 per cent. hydrochloric acid.*—When 100 grammes of polishings are extracted in the manner described, 26 grammes pass into solution, and of that amount 8·8 grammes are precipitated on the addition of alcohol. Therefore, in the alcoholic filtrate which contains 17·2 grammes of the soluble substances obtained from polishings the essential material should be contained.



Experiments were next carried out to test the accuracy of this suggestion. Polishings in quantities of 180 grammes were treated as in the previous experiment, and the combined filtrates from each 180 grammes were mixed with one and a half times their volume of 95 per cent. alcohol. After standing for two days the precipitate was filtered off, dissolved in warm distilled water, nearly neutralised with sodium carbonate, and the volume adjusted to 1080 cubic centimetres. 30 cubic centimetres of this suspension contained the alcohol precipitable substances (phytin) from 5 grammes of polishings.

Six fowls were fed on washed polished rice and received daily 30 cubic centimetres of this suspension of phytin. Cases of polyneuritis occurred, thus confirming the accuracy of the previously recorded experiments which proved the unimportance of phytin.

The alcoholic filtrate was nearly neutralised with sodium carbonate and evaporated at a low temperature until free from alcohol. The residue was diluted with distilled water to a volume of 1080 cubic centimetres. 30 cubic centimetres of this suspension contained the almost phytin-free soluble substances from 5 grammes of polishings.

Six fowls were fed on washed polished rice, and each received daily 30 cubic centimetres of this suspension. All remained healthy.

These experiments prove that of 5 grammes of sifted polishings required daily for the maintenance of weight and health in a fowl on a white polished rice diet, no less than 4·2 grammes are unimportant, and of the 0·8 gramme remaining probably only a part is essential.

Summary and Conclusions.

1. White polished rice when forming the staple of the diet in man has been shown to cause beri-beri.
2. Such white polished rice when fed to fowls produces in them a disease closely analogous to beri-beri in man. This reaction has been taken in this, and previous researches, as a test of the beri-beri producing power of a given rice when it forms the staple of a diet in man.
3. The addition of rice polishings to a diet of white rice is an effective preventive of the development of polyneuritis in fowls. Rice polishings comprise from 8 to 10 per cent. by weight of the original grain.
4. The substances contained in polishings which are effective in preventing polyneuritis are soluble in 0·3 per cent. hydrochloric acid, and are not precipitated from the solution on the addition of 95 per cent. alcohol in quantity sufficient to make the resulting mixture of proof-spirit strength. These substances comprise 16 per cent., or less, by weight of rice polishings, or 1·6 per cent., or less, by weight of the original unpolished rice grain.
5. The fats which are contained in rice polishings in comparative abundance have been proved of no importance in preventing polyneuritis.
6. Phosphorus compounds equal to 85 per cent. of the total phosphorus content have been proved to be unimportant in preventing polyneuritis.

Kuala Lumpur.

CASES OF PRIMARY CARCINOMA OF THE APPENDIX VERMIFORMIS.

BY ALEX. MILLS KENNEDY, M.B., CH.B. GLASG.,
ASSISTANT PATHOLOGIST TO THE GLASGOW ROYAL INFIRMARY; PATHOLOGIST TO THE GLASGOW MATERNITY AND WOMEN'S HOSPITAL.

(*From the Pathological Department of the Glasgow Royal Infirmary.*)

CASES of carcinoma of the appendix have always been considered of very great rarity, and, while admittedly they are rare, the number on record is steadily increasing with the custom of having all appendices removed at operation submitted to microscopical examination. From their situation they give rise to symptoms which direct attention to the appendix, and its early removal, preventing metastasis, goes a long way to explain the apparent non-malignancy of this tumour, which recently has been stated to be in the majority of cases a simple form of endothelioma.

In THE LANCET of Oct. 23rd, 1909, I reported a case of primary carcinoma of the appendix in a man, 49 years of age. This patient remained in good health without return of any symptoms, and ten months after his operation left for Canada, reporting himself by letter, a month later, quite

well. The specimen was found in the routine histological examination of appendices removed at operation. Since then I examined microscopically in the same way 40 appendices before I found the first of the two primary cases now reported. In this new case the appendix is constricted and the lumen occluded, the carcinoma arising at the site of the occlusion.

CASE 1.—The patient is a particularly healthy-looking young woman with a florid complexion. She is only 23 years of age. In November, 1908, she had her first attack of appendicitis; she was seized with sickness and vomiting which continued for about two days, and, shortly after the commencement of the sickness, severe pain in the right iliac region. The attack lasted three weeks. In November, 1909, she had a second attack similar in nature, but less severe than the first. Since her first attack she had always felt a little uneasiness or tenderness in her appendix region, more particularly when she had walked for some time. For three or four years previous to her first attack she had been subject to "bilious attacks," but, except for attacks of measles and scarlet fever, she had always enjoyed good health.

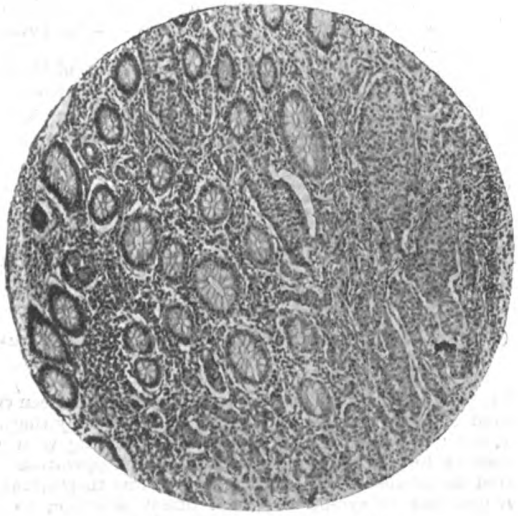
The patient was admitted to Mr. P. Paterson's wards at the Glasgow Royal Infirmary on May 6th, 1910, for operation in the quiescent period after her second attack. Examination revealed tenderness on pressure over the appendix region, but there was no distension of the abdomen nor rigidity of the recti muscles. On May 9th Mr. Paterson performed appendicectomy, and although the organ was readily removed it was found to be adherent to intestine in places.

Mr. Paterson states that at the operation there was nothing found which in any way suggested to him the presence of malignant disease in the appendix or its neighbourhood. The appendix measured 2¼ inches in length, and on external examination it was apparent that there was a constriction ⅞ inch from the distal end. The distal segment formed a spindle-shaped swelling; the proximal segment is narrower and cylindrical. The whole appendix was fixed in formalin 5 per cent., and, after washing, was divided longitudinally in the axis of the meso-appendix. On examining the cut surfaces it was at once seen that the external constricting marking corresponded to a definite stricture of the lumen, apparently a complete occlusion. This appeared to be produced by a thickening of the submucous layer and folding inwards of the mucous membrane, which was limited to the side of the appendix opposite its mesenteric attachment. The distal segment showed a uniform distension of its lumen with a creamy substance which proved to be pus. Nothing of note was apparent to the naked eye in the proximal segment.

Microscopical examination of appendix.—A portion about half an inch long was taken, and longitudinal sections were cut from it; this portion was taken from about the centre so as to include the occluded portion and part of the appendix on either side of it.

The lumen distal to the constriction is dilated and contains inspissated pus, and there is some flattening of the mucous membrane.

FIG. 1.



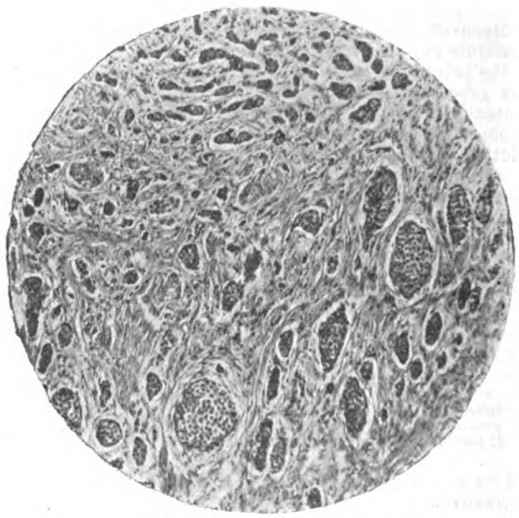
Carcinoma of appendix. × 90.

Proximally the lumen contains only a little mucus and blood, the latter probably the result of the operation. Throughout, for the greater part, there is a fairly uniform thickening of the submucous fibrous layer. At the site of the occlusion this layer is seen to thicken on the side opposite to the mesenteric attachment and then dip in and pass across the lumen, as a narrow band, to the opposite side. The mucous membrane on either side turns inwards and lines the constriction. The circular muscular layer also bends inwards for a short distance at this point.

In this constricted area, and limited to the half of the appendix opposite the mesentery, is an unmistakable carcinoma. In the mucous membrane adjacent to the distal side of the occlusion the carcinoma is seen extending from about midway across the lumen towards the peritoneum. In the mucous membrane carcinoma cells lie side by side with the normal glands, and apparently replace others. (Fig. 1.) The cells are fairly large, spheroidal, with relatively large nuclei, arranged in the alveoli of a scanty fibrous stroma, and forming solid masses of varying size. In short, the structure is that of a typical scirrhous carcinoma.

Passing from the mucous membrane outwards, the carcinoma is seen in the greatly thickened portion of the submucous coat as numerous smaller masses of epithelial cells in the alveoli of a much more abundant fibrous stroma. It passes through the circular muscular coat

FIG. 2.



Carcinoma of appendix. × 90.

as a few isolated masses between the muscle fibres. When it reaches the longitudinal layer of muscle it again forms a definite collection of similar solid masses of epithelial cells arranged as before, in the alveoli of a dense and fairly abundant fibrous stroma. (Fig. 2.) The tumour extends outwards to the peritoneal coat, which is thickened and covered with old adhesions.

Immediately beyond the constriction, adjacent to the carcinoma, there is a deep acute ulcer filled with pus, and extending almost right through the mucous membrane. The muscular coats beneath this ulcer are lost, their place being taken by the old adhesions already noted over the tumour. It appears very probable that this defect in the muscular coats and the formation of adhesions, together with the occlusion, are the result of a former ulceration of the appendix wall. Further, in this occluded area and, as yet, limited to it, there is now present an unmistakable scirrhous carcinoma. There is nothing further of note in the appendix beyond the fact that throughout the circular muscular layer there is considerable fatty degeneration.

The second new specimen was found post mortem, without the appendix having previously been suspected. In it also the appendix is constricted and occluded a short distance from its tip, which is bulbous and occupied by tumour.

CASE 2.—The patient was an extremely emaciated woman, aged 42 years, who was admitted to the medical wards of the Glasgow Royal Infirmary suffering from hepatic enlargement with ascites, and later was transferred to the surgical wards for abdominal drainage. She had been a heavy drinker for many years and had long suffered from indigestion after practically every meal. She had ascites for six months, and œdema of the legs for three months, before admission. On admission there was constant pain over the whole upper and left side of the abdomen, but she was unable to point to any one spot as being the site of greatest pain. The pain was sharp and stabbing and frequently very severe. She died suddenly a month after the operation.

Necropsy.—At the post-mortem examination the liver was found enormously enlarged (129 ounces), and showed an extreme degree of amyloid degeneration, with thickening of its capsule. The spleen and kidneys were also diffusely amyloid, and the capsule of the former was thickened. A firm fibrous mass of thickened adherent pleura, with a large cicatrix in the left lung under it, was found; it was evidently very old, and nothing was found anywhere else in the lung indicative of its nature. There had been a chronic peritonitis, evidenced by thickening and opacity of the peritoneum, with adhesions throughout the abdomen. The stomach and intestine throughout presented an œdematous condition but no other sign of disease.

The appendix was shorter than usual, turned back upon itself, and adherent to the adjacent loop of small intestine. On separation, it was seen that the tip of the appendix was occupied by a small hard nodule, the organ being club-shaped. Careful search was made, but no other tumour nor enlarged glands were found.

Microscopical examination of appendix.—The appendix was fixed in formalin, and longitudinal sections of the whole organ, in addition to transverse sections of the tumour, were prepared. The tip of the

appendix was demarcated from the remainder and bent inwards towards the meso-appendix, and in it there was present a carcinoma.

There were old adhesions round the appendix, and the muscular coats showed some fibrosis. There was considerable thickening of the submucous fibrous coat throughout, and the mucous membrane was also thickened and fibrosed. About ¾ inch from the tip the appendix is completely occluded. Here sections show the circular muscular layer extending right across the organ, bounded on either side by the thickened layer of submucous fibrous tissue. On the mesenteric side the longitudinal layer of muscle dips inwards for a short distance at the site of occlusion, but on the opposite side it passes right over and round the tip.

Beyond the occlusion there is no lumen; the mucous membrane is altogether lost, and its place and the cavity are occupied by a characteristic carcinoma. The tumour appears as two nodules. One, immediately adjacent to the occlusion above mentioned, is completely surrounded by a thickened layer of submucous tissue, and apparently replaces the mucous membrane. The other is situated distally, nearer the tip, which, as above noted, is turned round towards the mesenteric attachment, and is surrounded by muscular and fibrous tissue. Externally the longitudinal and circular muscular layers are distinct, and the tumour here also is situated within a layer of fibrous tissue corresponding to the submucous coat. Between these two nodules a layer of muscle corresponding to the circular layer is present; it is infiltrated with tumour, and the infiltration extends in the circular muscular layer on either side of the distal nodule, but does not involve the tip.

The cells are spheroidal, the protoplasm is abundant, and the nuclei are relatively large and dense; they form solid masses, surrounded by a dense though rather scanty fibrous stroma. The two nodules have practically the same characteristics, and are undoubtedly scirrhous carcinoma. Between the two nodules, and spreading laterally, masses of similar cells are seen between the fibres of the circular ayer of muscle.

During the past 11 months I have examined, as a matter of routine, the appendix in over 350 necropsies, yet this last case is the only primary tumour I have yet found in it. I have twice found secondary tumours in it, and in both cases they were carcinomata secondary to carcinomata of the stomach. They each showed the same structure as the primary growth in the stomach.

The three primary carcinomata of the appendix which I have now reported present features so similar as regards their site of origin that they are of considerable interest in view of the question of the etiology of tumours in general. In the first case the appendix was divided into two segments, no doubt the result of cicatrisation of previous ulceration, and in the sequestrated distal portion the carcinoma was situated. In the second case there is a complete occlusion of the lumen, in all probability due to the same cause, and in this constricted area, and as yet limited to it, the carcinoma is present. In the third case the appendix is also completely occluded in the same way near its tip, and beyond the occlusion, filling up the cavity and replacing the mucous membrane, is the carcinoma.

In the first two cases, and probably in the third also, the patient had had more than one attack of ordinary appendicitis; from the histological appearances we can conclude that it is highly probable that in each case a certain amount of localised ulceration of at least the mucous membrane occurred, followed by cicatrisation in the process of healing. No doubt this causes considerable disturbance and separation of the epithelial cells of the mucous membrane, and in each of these cases a carcinoma has arisen at the situation of the damage.

As previously pointed out, these cases are of considerable interest in view of Ribbert's theory of tumour formation—viz., that tumours arise from a partial or complete separation of cells, or groups of cells, from their organic continuity—that is to say, from mechanical isolation.

Glasgow.

THE SURGICAL AID SOCIETY.—Under the presidency of the Lord Mayor of London the Surgical Aid Society held its forty-eighth annual meeting at the Mansion House on Dec. 6th. Mr. Samuel Watson was reappointed honorary treasurer and Mr. F. R. Fisher, the senior surgeon to the society, was appointed honorary consulting surgeon. Sir James Crichton-Browne proposed, and the Rev. J. Scott Lidgett seconded, a vote of thanks to the medical officers who gave their services to the society. This was carried unanimously. Mr. E. Muirhead Little replied. In moving a vote of thanks to the Lord Mayor Archdeacon Sinclair referred to the satisfactory report which had been issued. He pointed out that the total net income for the past year was nearly £28 400, that the annual subscriptions showed an increase of £887, life subscriptions an increase of £359, and contributions from local branches an increase of £329. There had been increase in expenditure for relief of £1562, but the cost of management had been reduced by £316. In the course of the proceedings the secretary announced subscriptions amounting to £271.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF ENCHONDROMA OF A PHALANX FOLLOWING INJURY.

BY THOMAS H. KELLOCK, M.C. CANTAB., F.R.C.S. ENG.

IN view of the importance which nowadays attaches to injuries sustained by workmen in the course of their occupation, any uncommon or unexpected sequel of such is worthy of record when the question of disablement and compensation arises.

In the case now reported there seems to be no reason to doubt that the injury received was the direct cause of the condition that resulted. Those who first saw the case considered the disease of the phalanx to be of a tuberculous nature; it was treated as such for some time and a very doubtful prognosis given as to the ultimate usefulness of the finger, which, being the index of the right hand, was of considerable importance and value. The finding that the enlargement was due to enchondroma materially altered the line of treatment to be adopted and also the prognosis both from the patient's point of view and that of his employers.

The patient was a young man, 18 years of age, an engine fitter by trade. His father had died from "brain fever," otherwise there was no family history suggestive of tuberculosis, syphilis, or new growths. When 3 years of age the patient was said to have suffered from "consumption of the bowels," and when between 6 and 7 he had measles. With these exceptions he had had no previous illnesses. In the course of his occupation he had often received blows on his fingers, but had never been seriously injured. In December, 1908, whilst at his work, his right hand was resting, palm upwards, on an iron plate waiting to receive a bolt which a fellow workmen was knocking out. The bolt came through and rested on the first phalanx of the index finger. The other man, thinking it was not through, gave it another hard blow, the result being that the patient's finger received the full force of this between the bolt and the iron plate. The finger was considerably bruised and painful, but he continued at his work until March 31st, 1909, when, finding it swollen and some limitation of movement at the first interphalangeal joint he first sought advice about it. Scott's dressing was then applied and the finger kept on a splint for two months, and after that it was kept in a plaster-of-Paris casing for a further ten months, during which time he did no work. He suffered no pain or inconvenience except that the finger "throbbed" if he got hot by any exertion.

When seen in March, 1910, the proximal phalanx of the right index finger was found to be considerably enlarged, the enlargement being of a fusiform shape and extending the whole length of the bone. It felt densely hard, but was not tender; the skin was neither adherent nor discoloured over it, but was a little thin and shiny from disuse. Flexion at the first interphalangeal joint was limited in extent, but what there was was easy and free, the interference with movement being apparently more mechanical than pathological. No enlarged glands could be felt either at the elbow or in the axilla. A skiagram showed the bone to be larger than normal; the centre appeared to be comparatively clear, but the peripheral parts very dense, as if the bone were a mere hard shell with well-marked external and internal surfaces. The condition was thought to be probably due to an unabsorbed collection of blood in the interior of the bone—a so-called "blood cyst."

An incision was made down to the bone in the long axis of the finger between the lateral nerve and the extensor tendons. The periosteum was very easily pushed back, exposing a markedly sclerosed condition of the surface of the bone. This was then opened with a gouge, the bone being brittle and breaking easily, almost like a dry egg-shell. The cavity was found to be filled with an almost dry gelatinous material of a light brown colour. This was easily scraped out, leaving a well-defined cavity the contour of which was formed of hard, smooth bone; the cavity was filled with decalcified bone, the periosteum brought together over the opening made by the gouge, and the skin sutured. Primary union occurred. On examining the tissue that had been removed it

was found to contain a large number of cartilage cells with a more or less homogeneous matrix.

The patient resumed work about six weeks after the operation. When seen in September last the bone was found to have diminished slightly in size. He had had no pain or inconvenience in it, and the movement at the joint was easy and free to the extent of a right angle.

Queen Anne-street, W.

NOTE ON A CASE OF IMMEDIATE SERUM REACTION.

BY T. THOMSON RANKIN, M.D. GLASG.,
AND
A. M. PRYCE, M.B., CH.B. EDIN.,
ASSISTANT MEDICAL OFFICERS, CITY HOSPITALS, LEEDS.

THE following case is of interest in so far as it shows an immediate reaction to a single dose of anti-diphtheritic serum.

A female infant, aged 21 months, was admitted to the Leeds City Hospitals on July 5th, 1910, suffering from diphtheria. On admission she received 5000 units of concentrated diphtheria antitoxin (P. D. and Co.) by subcutaneous abdominal injection. Within 15 minutes a profuse and typical urticarial eruption appeared on the face, arms, back, chest, and legs. This rash lasted two days and disappeared gradually; the highest temperature noted during its presence was 101·4° F. On the eleventh day of the disease and the seventh after the injection another urticarial eruption developed and the temperature did not exceed 100°. The patient did well and was discharged on August 24th. Prior to her discharge 2 c.c. of sterile water were injected subcutaneously without any reaction being made manifest.

The occurrence of immediate and accelerated reactions following repeated injections of anti-diphtheritic serum has been noted and recorded, but the appearance of serum phenomena so soon after a single injection has not come under our notice. To avoid the possibility of error, we injected the sterile water and inquired into the history of the child and mother. The failure of the sterile water to produce any reaction is evidence of the fact that the phenomena were due to the serum. We were able on close inquiry to exclude the usual causes of urticaria, such as unsuitable diet, drugs, &c.

It has been suggested that a woman who has had diphtheria antitoxin may transmit to her child a tendency to be abnormally sensitive to serum, as occurs in the case of guinea-pigs. We are able to exclude this possibility, as the mother of the child never had diphtheria or diphtheria antitoxin.

We are indebted to Dr. A. E. Pearson for his kind permission to publish these notes.

Leeds.

NOTE ON A CASE OF MUCOUS COLITIS SUCCESSFULLY TREATED BY VACCINE-THERAPY.

BY G. C. STEELE-PERKINS, M.D. EDIN., M.R.C.S. ENG., L.R.C.P LOND.

A FEMALE, aged 23 years, came to me on Oct. 1st, 1909, with a history of mucous colitis on and off (diagnosed as such by her medical attendants) for the past eight years. The present attack commenced six months ago. Her symptoms were loose motions, the passing of mucus and shreds of membrane, straining at stool, constipation, and pain and tenderness in the region of the ascending, but especially in the region of the descending, colon. She was feeling quite unfit to do anything, became easily tired, and was generally out of health.

Until Feb. 28th, 1910, I tried a variety of treatment, including rest, dieting, decoction of cortex simarubæ, massage of the colon, &c., but the patient showed no improvement. On the above date I sent specimens of her blood, urine, and fæces to Dr. J. W. H. Eyre for bacteriological examination, who on March 3rd reported as follows: "Urine: sterile. Fæces show that the normal bacillus coli is practically absent, but its place has been taken by streptococcus pyogenes longus and a bacillus having characters intermediate between the bacillus lactis aerogenes and bacillus pneumoniæ of Friedländer. Blood: Opsonic index to the streptococcus 0·7, and to the bacillus 0·6." Vaccines were prepared from each of these micro-organisms. From March 7th to May 31st I injected the patient with the prepared vaccines of both the streptococcus and bacillus, in doses from 5 millions to 25 millions, at intervals of about eight days.

The details of these injections and of the opsonic indices are as follows:—On March 7th and 14th, 5 millions each of the streptococcus and bacillus. March 18th: Opsonic index to streptococcus 1·3, to bacillus 0·9. 21st: 10 millions of the bacillus. 29th: 10 millions each of the streptococcus and bacillus. April 6th: Opsonic index to streptococcus 1·01, to bacillus 0·8. 7th: 10 millions each of the streptococcus and bacillus. 15th: Opsonic index to streptococcus 1·1, to bacillus 0·5. 16th: Streptococcus 10 millions. 20th: Bacillus 10 millions. 27th: Opsonic index to streptococcus 1·09, to bacillus 1·1. 28th, May 6th and 14th: Streptococcus 10 millions and bacillus 25 millions. May 18th: Opsonic index to streptococcus 1·0, to bacillus 1·2. 23rd and 31st: Streptococcus 25 millions, and bacillus 25 millions. On May 31st the patient told me she had not suffered severe pain for over six weeks, that she was considerably better in health, and was passing a much less number of shreds; there was no tenderness of abdomen. Dr. Eyre reported: "No streptococci in shreds from bowel."

From June 8th to Sept. 13th I injected the patient with the bacillus vaccine in doses from 25 to 50 millions at intervals of about a fortnight, and on the latter date the patient informed me that she had been feeling very well for several weeks. The details of these injections and of the opsonic indices are as follows:—June 8th: Bacillus 25 millions. 14th: Opsonic index to streptococcus 1·1, to bacillus 0·96. 25th, July 9th and 23rd: Bacillus 50 millions. July 28th: Opsonic index to streptococcus 1·6, to bacillus 1·2. August 5th, 22nd, and Sept. 2nd: Bacillus 50 millions. Sept. 7th: Opsonic index to bacillus 1·04. 13th: Bacillus 50 millions.

On Oct. 11th Dr. Eyre reported: "The specimens of fæces show a practically normal bacteriological flora. The normal bacillus coli was present in what I should consider normal numbers. The bacillus from which the vaccine was prepared has entirely disappeared, and so also has the streptococcus longus. A few colonies of streptococcus brevis (a normal inhabitant of the intestinal tract) were noted."

During the vaccine treatment the patient continued having careful massage of the colon, was dieted, and non-irritating aperients were given when necessary. The doses of the vaccine were regulated partly by the clinical symptoms and partly by opsonic estimations of the blood.

Oct. 12th: The patient continues in good health, feels quite well, and passes no shreds of mucous membrane.

Wimpole-street, W.

BRITISH DENTAL ASSOCIATION.—The annual meeting of the metropolitan branch of the British Dental Association was held in the school buildings of St. Bartholomew's Hospital on the evening of Dec. 7th, Mr. W. B. Paterson, dental surgeon to the hospital and president of the branch, in the chair. After the transaction of formal business, Mr. Paterson delivered an address, in the course of which he described the origin and growth of the dental department of the hospital, the scope of its work as a charity, and its teaching in the medical school. The department was founded in 1837, when Mr. Arnold Rogers was appointed the first dental surgeon, with the duty of visiting the hospital one day in the week. Upon his retirement in 1849 he was succeeded by Mr. Tracy, who in turn was followed by Mr. Alfred Coleman. In 1879 the department was reconstituted and met twice weekly. The department was now in charge of four dental officers and met daily. The dental teaching of medical students was carried out on definite lines, and quarterly classes were held for those about to commence surgical dressing in the wards. The elements of dental surgery were taught, and extraction operations practised in the dissecting rooms. Attendance at the casualty dental department and dressership in the department were open and free to all students, and were specially recommended to those who intended joining the Naval and Army Medical Services. After the address the members visited the great hall of the hospital, the new pathological block, and museum. The proceedings terminated with a conversazione in the library.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Septicæmia Hæmorrhagica.—Gastric and Intestinal Hæmorrhages.—Fractures of Patella.

A MEETING of this section was held on Dec. 13th, Mr. RICKMAN J. GODLEE, the President, being in the chair.

Mr. W. G. SPENCER read a paper entitled "Septicæmia Hæmorrhagica: Severe Capillary and Parenchymatous Hæmorrhage of Septic Origin." He said that there was a class of grave and fatal hæmorrhages which were not included under the subjects of primary or secondary hæmorrhages, nor could they be ascribed to any congenital lesion such as hæmophilia, nor to degenerative lesions such as occurred in Bright's disease or were induced by the toxic influence of alcohol. Indeed, those causes of hæmorrhage were excluded from consideration by the speaker, and none of the cases referred to were predisposed to hæmorrhage from those causes. The peculiarity of the hæmorrhage he proposed to discuss was that it might occur from a mucous or serous membrane without any naked-eye breach of surface; or it might happen from a raw surface without any special blood-vessel being opened; or if into an organ, there was parenchymatous hæmorrhage without any preliminary traumatism or degenerative process in that organ. Such hæmorrhages were well-known complications of the specific and tropical fevers, as well as of scurvy. One could not attribute such hæmorrhages to an excess of pulse-tension, for, indeed, the hæmorrhages, whether from the nose or gastro-intestinal canal, continued to recur when the patient had become very weak. In bringing forward cases which had come under his observation, he was well aware that he could deal only inadequately with the essential part of the subject—the bacteriology. For that was the clue to the treatment, whether by an antitoxin given immediately or by auto-vaccination as soon as possible. His attention was first drawn to the subject by Klein's experiments on a variety of streptococcus causing hæmorrhage. In 1897 Klein received from Dr. J. G. E. Colby of Malton fluid taken from vesicles on the skin of a man who two or three days before had been engaged in skinning sheep dead from puerperal septic œdema after lambing, the so-called "gargel." Klein cultivated a streptococcus from the material which, when injected subcutaneously into guinea-pigs, caused subcutaneous and intermuscular connective-tissue hæmorrhages around the site of inoculation, along with blood effusions into the pleural and peritoneal cavities. The same results followed the injection of cultures into rabbits and sheep. Returning to human pathology, there occurred cases of hæmorrhagic empyema and ascites. Oliver had described cases of thoracic empyema followed by fatal hæmorrhagic oozing from the wall of the cavity; the organisms found were the diplococci of Friedländer, not the pneumococcus. In those cases injury to an intercostal artery or pulmonary vessel was excluded. Hæmorrhagic ascites had proved very fatal, doubtless due to infection by organisms, but he was not aware of any definite report as to the organisms present. Under the term of purpura a collection of hæmorrhagic diseases were discussed in works on medicine. Some of those cases were traceable to streptococcal infection, especially when a complication of puerperal fever occurred. Melæna neonatorum formed another class of fatal hæmorrhagic disease. The acute hæmorrhages which complicated diphtheria of the fauces were very fatal. Acute hæmorrhages into the stomach, as shown by black vomit, constituted a grave complication. In medical practice they followed the specific and tropical fevers; in surgical practice they occurred late in such cases as intestinal obstruction, gall-bladder suppuration, and gangrenous appendicitis, and might follow operations when sepsis could not be prevented. He had seen that fatal termination in the various forms stated, but unfortunately he had no bacteriological information to give. Hæmorrhagic pancreatitis was a well-known form of parenchymatous hæmorrhage, in which the exact type of organism causing the affection could not yet be stated with certainty. There did not appear to be sufficient reason to ascribe the hæmorrhages to bacillus coli communis, which was the organism generally found in such abdominal complications. Dr. F. W. Andrewes had published the post-mortem examination of a case of muscular hæmorrhage following typhoid fever. Hæmorrhages of a similar character might be produced by poisons such as phosphorus and benzine both in human beings and, experimentally, in animals. It would seem likely that the actual influence on the blood-vessels was through the agency of toxins produced by such poisons, and therefore the actual production of the hæmorrhages might essentially not differ from those originated by organisms. He referred to cases of acute hæmorrhagic cellulitis in which on incision no distinguishable amount of pus escaped, but blood poured out most freely. Several grave cases of hæmorrhage from the kidney and bladder had come under his notice which could not be classed with common causes of hæmaturia. Hammersley had described a patient who had attacks of pain in the right kidney with severe hæmaturia which was relieved by removing an inflamed appendix, and he attributed the renal affection to infection spreading from the appendix. Eve recorded a case of fatal hæmaturia due to psorosperms. Posner in a man subject to attacks of hæmaturia found amœbæ. He had included in his paper cases which differed widely from one another. But they were all grave and obscure. Some cases of septicæmia hæmorrhagica had been certainly caused by streptococci. The occurrence of the hæmorrhage might be explained by supposing the organism to collect especially in contact with the walls of the blood-vessels. Under the effect of the toxins the walls of the vessels became weakened and gave way, so as to allow the escape of blood. That occurred without intravascular thrombosis, which in ordinary acute inflammation must be the chief factor in preventing hæmorrhage. Neither was there any massive collection of leucocytes at the inflammatory focus, so that very little pus formed. The identification of streptococci as the commonest organism suggested an immediate recourse to streptococcal antitoxin, whilst the identification of the particular organism was being made. The first case of success by the use of streptococcal antitoxin was reported by Ballance and Abbott. A finger was pricked at a necropsy on a case of suppurative peritonitis, and acute septicæmia set in, complicated by cutaneous hæmorrhages. Immediate relief followed the use of streptococcal antitoxin. When the infection was not due to streptococci, or was a mixed infection with staphylococci or bacillus pyocyaneus, the preparation and injection of an auto-vaccine should be carried out as quickly as possible. The extravasated blood clotted readily, and that explained the fact that the administration of calcium chloride had had no influence on the hæmorrhage.

Mr. JONATHAN HUTCHINSON read a paper on Gastro-intestinal Hæmorrhage, usually of septic origin, occurring after abdominal operations. He said that that form of hæmorrhage, shown as a rule both by hæmatemesis and melæna, was due in most cases to very small ulcers or erosions in the stomach wall (occasionally also in the duodenum, &c.). He narrated a case at length in which death occurred on the seventeenth day after cholecystectomy. The first operation was done for gall-stones and cholecystitis; at the same time an abscess above the liver was drained. After the onset of hæmorrhage on the ninth day the stomach was explored and one bleeding spot in its wall secured by ligature, another being cauterised. Twenty-three similar cases of gastric hæmorrhages after operation, occurring in the London Hospital in the course of three years, were analysed. It was found that the condition for which the operation was done was in 80 per cent. of a septic nature, suppurative appendicitis providing the majority—viz., 13 cases out of 24. In 3 out of the 24, acute ulcers of some size were found post mortem; in the rest small erosions only were present. One patient only recovered after repeated and severe hæmorrhage; all the others proved fatal. Sixteen cases of similar nature, in which no operation had been done, were also analysed. Those occurred in the medical wards of the London Hospital during the same period of three years. The disease for which those patients were admitted was of septic nature in the same proportion as those operated on—i.e., 80 per cent. It was certain that an alteration in the blood due to a poison usually of septic origin was the main factor in the

production of gastric erosions of this kind. If an operation had been performed it was a mere coincidence, except in the rare cases where it was responsible for abdominal sepsis. Hæmorrhage of that nature, whether occurring after an operation or as a complication of another disease, was of very grave prognosis. A few cases, however, proved that spontaneous recovery might ensue. Operative interference did not appear to hold out any material prospect of success in checking the bleeding, but further experience was required to decide that point. Out of the 40 cases analysed the only one in which it was tried was the one in which Mr. Hutchinson had operated.—The PRESIDENT suggested that in some of the cases the condition was not due to sepsis, but was to be attributed possibly to the influence of the anæsthetic.

The meeting concluded with the reading of a paper by Mr. A. E. JOHNSON on Fractures of the Patella without Separation of the Fragments.

CLINICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on Dec. 9th, Sir A. PEARCE GOULD being in the chair.

Dr. WILLIAM HUNTER showed a case of Addisonian Anæmia (Idiopathic Pernicious Anæmia). The patient, a male, came under observation in July, 1900, showing typical features of this disease—red-blood cells 25 per cent., hæmoglobin 35 per cent. The case was treated by strict oral antiseptic measures, combined with the administration of antistreptococcic serum. The recovery was immediate and striking; in three weeks the blood showed red cells 65 per cent., hæmoglobin 75 per cent., subsequently rising to 94 and 104 per cent. respectively, when the case was shown before the Clinical Society. The case was then described in a paper before the Royal Medical and Chirurgical Society in January, 1901. The patient had been under close observation ever since in order to thoroughly test the methods of treatment mentioned. A relapse occurred in the end of 1901, the red blood cells falling to 60 per cent., followed by rapid recovery—red blood cells 92 per cent. Another relapse at the end of 1902—red blood cells 50 per cent.; recovery in 1903—red blood cells 80 per cent. A severe relapse at the end of 1903, red blood cells falling to 30 per cent., followed by striking recovery in three months—red blood cells 90 per cent., hæmoglobin 120 per cent. The patient had remained without any relapse during the last seven years. The present condition of the blood is, red blood cells 105 per cent., hæmoglobin 115 per cent. The case showed, at the onset of the disease and during the first three years—1900–03—while he suffered from the relapses mentioned, the characteristic clinical features involving (1) glossitic gastro-intestinal disturbances; (2) hæmolytic changes with evidence in the blood and urine; (3) pyrexia; and (4) peripheral nervous disturbances. During the last seven years these features had been absent.—Dr. N. DALTON observed that the gastric cases of this affection were the best from the point of view of prognosis, apparently getting well with the administration of bismuth, excepting, of course, cases of pernicious anæmia following cancer.

Dr. JAMES GALLOWAY and Dr. W. J. FENTON showed a case of Stokes-Adams Symptoms in a lad aged 18 years. The patient was fairly well developed; there was no history of any serious illness till the month of May, 1910. He was then employed in an office in the City, and had passed through a hard winter's work. During the month of May he commenced to suffer from repeated partial fainting attacks, and for that reason medical advice was sought. When he came under observation the pulse frequency at the wrist varied from 32 to 40 per minute. Occasionally marked irregularity occurred, but the irregularity appeared to be always of the same type—two or three beats with long intervals, followed by a succession of beats with short intervals. The fainting attacks occurred with no warning—a slight exertion was often sufficient to bring them on. Occasionally he had lost consciousness for a very short time in these attacks, but usually they were transient and consciousness was not completely lost. On several occasions climbing to the top of an omnibus made him inclined to be faint. Rarely several fainting attacks had occurred in rapid succession. There was no evidence of valvular lesion nor of cardiac enlargement or hypertrophy. No other visceral disease was present. Since the commencement of his attack the patient had rested, but the conditions described persisted. Fainting attacks were less numerous. The sphygmographic and string galvanometer tracings kindly made by Dr. Thomas Lewis of the heart's action were shown, and gave evidence of very complete "heart-block."—Dr. F. J. POYNTON discussed the question whether the patient would get well or remain an invalid, and supposed that congenital affection of the bundle of His was against a good prognosis.—Dr. GALLOWAY said that he would do his best to bring the patient again before the section.

Dr. GALLOWAY showed a case of Multiple Telangiectases of recent origin. The patient, a man, aged 35 years, had been in the army, and had served in the West Coast of Africa, India, and Burma. He had probably had syphilis, but had no regular treatment. He was invalided out of the service from Burma on account of lung disease. There was now evidence of consolidation in patches throughout the right lung; there was a slight degree of fever, and a few tubercle bacilli were found in his expectoration. There was an enlargement of the liver. About 18 months ago he noticed the development of the red spots on the skin. These occurred mainly on the face, neck, and shoulders; several dozens might be counted. A few others existed on the body and on the lower extremities. They consisted of permanently dilated capillaries, radiating from a central point—large "spider-nævi." The centre of each system had a dark purple punctum which increased in size, forming in some cases an angioma of the size of a large pea. In some cases a considerable area of the skin was covered with the thread-like telangiectases, but without the elevated central point, as on the right side of the neck. They bled profusely when injured, and one situated on the edge of the left nostril had given much trouble for that reason. No telangiectases were visible on the mucous membranes; there was no hæmaturia nor melæna. Hæmoptysis had been very profuse. No history of a similar condition in his family was obtainable.

Dr. H. E. SYMES-THOMPSON showed a case of Infantilism. The patient was a female, aged 34 years, single; height, 3 feet 2½ inches; weight, 3 stones. Nothing abnormal was noticed until the patient was between 3 and 4 years old, when she ceased to grow. She went to school until she was 14, and learnt to write, sew, and knit, but not to read. Her memory was good, and she knew the numerals and alphabet. She was babyish in her ways, and was fond of dolls. The circumference of her head was 20½ inches. There was some kyphosis and scoliosis. The teeth were fair, the hair of the head was normal, but the mammæ were undeveloped, and there was no axillary or pubic hair. Skiagrams showed a backward condition of ossification, the epiphyses of the long bones not being joined to the shafts and the ossa innominata were incomplete. The family history presented nothing of note. The patient's general health was fair. The bowels were regular and the motions normal. The case did not appear to be secondary to rickets, syphilis, or any other disease, and it apparently fell into the classification of Hastings Gilford as an instance of primary infantilism, or ateleiosis.

Dr. F. PARKES WEBER gave details of a case of Ateleiosis in a man aged 42 years. In this patient physical development was said to have been arrested at about the age of 9 years. The case was exhibited to the Section for the Study of Disease in Children at the Royal Society of Medicine on May 27th, 1910.

Dr. W. ESSEX WYNTER showed two cases of Henoch's Purpura. Case 1 was a female, aged 11 years, admitted on Sept. 26th, 1910. She had had rheumatism when 4 years of age, but no other illness. There was pain in the abdomen for one week, independent of food; and for four days pain, swelling, and stiffness in the left wrist. Purpuric spots appeared on the leg at the commencement of the illness, and on admission extended to all the limbs. Systematic examination disclosed no abnormality of organs; splenic dulness extended to the costal margin, but the edge could not be felt. Pain was complained of in the epigastric and umbilical regions, and there was some general abdominal tenderness. The patient vomited on the day after admission, some blood being present in the vomited matter. On Oct. 1st there was considerable intestinal hæmorrhage, and that recurred on the 4th. On the 15th a fresh crop of purpuric spots appeared on the right foot. On the 24th, the symptoms having subsided, the patient was allowed to get up, but on the 28th fresh purpuric spots appeared on the legs, and there was some œdema of the left foot. On Nov. 7th, after getting up for

some days, fresh purpuric spots appeared on the inner side of the left ankle, and on the following day blood and albumin appeared in the urine. Microscopically blood corpuscles were seen, but no tube casts; no globulin was present and no œdema. The albumin had gradually diminished, but was still present and varied in amount. Weight, pulse-rate, temperature, respiration, and quantity and specific gravity of urine and blood showed no departure from normal. Throughout there was marked pallor of the face, the lips remaining red. Case 2 was a male, aged 13 years, admitted on Oct. 19th, 1910. A similar illness occurred two years before. Five days before admission pains were felt in the legs and purpuric spots appeared. The patient vomited the day before admission. When first seen there was abdominal pain and a purpuric eruption of the legs and feet; the ankles swelled. Systematic examination disclosed no abnormality of organs; splenic dulness extended to the costal margin, but the edge could not be felt. The symptoms subsided in three days and the patient was allowed to get up on Oct. 28th. On Nov. 7th there was a fresh purpuric eruption on the right leg and the left elbow. On the 8th there were blood and albumin in the urine; corpuscles and blood-casts were seen in deposit but no epithelial casts; no œdema. Several attacks of vomiting occurred. On the 24th there was intestinal hæmorrhage. Pulse- and respiration-rate, temperature, quantity of urine, and body-weight remained normal. The blood examination showed 19,000 leucocytes, red cells 4,800,000, and 65 per cent. hæmoglobin.

Dr. GALLOWAY described a case of a child who came to him with symptoms similar to the two cases shown. The symptoms in his case followed indulgence in nuts and blackberries. He asked if it was a wise thing to isolate such cases under a special name.—Dr. F. DE HAVILLAND HALL quoted a case in which there was a difficulty of diagnosis between Henoch's purpura and intussusception. He mentioned oil of turpentine as a useful remedy in purpuric cases.

Mr. LIONEL E. C. NORBURY showed a case of Perforated Tuberculous Ulcer of the Ileum. The patient, a male, aged 39 years, had a history of occasional attacks of epigastric pain; there was no history of constipation. He was admitted with eight hours' history of acute abdominal pain, chiefly in the lower half of the abdomen. The patient was doubled up; he vomited later. On examination the temperature was 100° F., the pulse 100 per minute, and respirations 20. There were tenderness and rigidity of the abdomen, chiefly of the lower half; liver dulness was normal. An operation was performed nine hours after the acute onset. Exploratory cœliotomy—no free gas; small amount of free fluid in abdominal cavity, and lymph; stomach and appendix normal; hard swelling found involving small intestine 2 feet from cæcum; lumen of bowel much narrowed; small perforation in wall of bowel at that situation; resection of 4 inches of ileum with ulcer; end-to-end anastomosis; dry sponging of pelvic cavity; suture of parietes, no drainage. There was an uninterrupted recovery. Microscopical examination proved ulcer to be "tuberculous." Examination at operation showed no other ulcers in the small intestine.

Mr. LAWRIE H. MCGAVIN showed a case of Varix of the Right Superficial Epigastric Vein. The patient was a male aged 52 years. He stated that in 1901, when jumping overboard to save a man, he strained himself. He suffered from severe pain in the stomach at the time, which "doubled him up." The veins on the abdomen became enlarged after that, and had been increasing in size since. The patient now showed well-marked varix of the superficial epigastric vein of the right side. The vein was extremely tortuous, and presented lateral dilatation and pouching of the wall, especially in the region just above the umbilicus. The condition might possibly have been brought about by rupture of the vessel wall, with consequent thrombosis.

Mr. MCGAVIN also showed a case of Trunk Lesion of the Fifth and Sixth Cervical Nerves; keloid development in scars. The patient was a male aged 6 years. He was admitted into hospital on May 13th, 1910, and, as a result of being run over by a cart, was suffering from a wound of the face and fractured left clavicle. The wounds were cleaned up and sutured and the clavicle put into position. It was noticed that there was paralysis of all the nerves of the arm, with the exception of the ulnar. It was thought at the time that that was due to pressure from effused blood, but as the condition did not clear up a flap was turned back from the shoulder and the clavicle exposed (June 9th). The outer end of the clavicle had become depressed and was producing pressure. That was lifted up and the fractured ends were wired. The patient was discharged on June 23rd. The wound had healed perfectly, and the paralysis was apparently clearing up. Returning to hospital a week ago—i.e., six months after—it was found that every scar had become keloid in character, both those produced at the time of the accident and those subsequently by operation.

Mr. L. VERNON CARGILL showed a case of Double Proptosis due to a growth invading each orbit. The patient was a male aged 20 years. He was a sailor and native of Barbados; now an in-patient at King's College Hospital. The family history was unimportant. His general health had been always good. He had a sore on the penis two years ago. Last June his attention was first drawn to a painless swelling under the nasal half of the upper lid of the right eye. He went to the "Dreadnought" Hospital in July, and there was then proptosis of both eyes but more marked on the right side. There was a bulging forward of both upper eyelids caused by a soft, non-pulsating swelling beneath, situated in the upper and inner part of each orbit. The ocular movements were slightly restricted in all directions, but more particularly upwards, but there was no ocular paralysis and no diplopia. The optic discs were normal, there was no lesion to be seen in either fundus, the pupils were normal, as were the visual acuity and the visual fields. There was no evidence of any of the cranial nerves being affected. At the end of July Dr. R. E. Bickerton removed a small portion of the growth beneath the right upper eyelid for examination. Photographs were taken on August 11th which showed the conditions then present. In them the right eyelid, which had been recently incised for the removal of a portion of the growth, was drooping. The bulging of the eyes and the orbital swellings had since then gradually increased and been accompanied by some occasional pain at night between the eyebrows, over the root of the nose, and in the temples. His proptosis was now so extreme, especially on the left side, that he was unable to close his eyelids properly, and epiphora had become troublesome and constant. The movements had become more limited, the tumours had increased and extended further round on the nasal sides of each orbit, and the eyes were displaced downwards and were further apart, so that the distance between the pupils was as much as 78 millimetres. The caruncle and plica semilunaris on each side were swollen, chemosed, and injected. A swelling had appeared in the forehead, chiefly over the region of the left frontal sinus, and extending to the upper margin of the left orbit, which was tender, felt hot, and pitted on pressure, the bone beneath feeling raised. That showed slightly in the full-face photograph. Some enlarged glands were to be felt on both sides of the neck and there was a soft glandular-like swelling under the tongue. Eyes and vision still remained normal. There was no loss of smell. Dr. StClair Thomson had kindly examined the nose and sinuses and reported as follows: "The nose and post-nasal space are quite free and healthy. There is no stenosis, pus, or new growth in any of these spaces. Transillumination shows both maxillary sinuses equally translucent. There is tenderness over both frontal sinuses, more over left, where there is slight œdema. The growth might be primary in the frontal sinuses." There was nothing further abnormal to be felt or detected in the chest, abdomen, or elsewhere. The blood examination gave "R.B.C., 4,430,000; W.B.C., 9000; hæmoglobin, 75 per cent.; polymorphs, 31 per cent.; eosinophiles, 9 per cent.; monomorphs, 55 per cent.; hyalin bodies, 5 per cent.; very numerous platelets." His colour precluded any note being added as to his complexion. A few days ago Mr. Cargill removed a portion of the growth from the left orbit, sections of which had been examined by Dr. Emery. They showed the structure to be that of a hæmangiolymphadenoma, consisting of young connective tissue with the formation of definite lymphatic follicles around the blood-vessels, the growth having started in the perivascular lymphatics. The sections of the first portion removed by Mr. Bickerton were first regarded as round-celled sarcoma but they showed the same structure in an earlier stage. A. Q. Silcock in 1888 showed a case[1] of a child, aged 9 years, with a tumour

[1] Transactions of the Ophthalmological Society, vol. viii., p. 53.

affecting both orbits. The microscopical examination was said to present the characters of round-celled sarcoma, but the same mistake might have been made in that case as in the early sections from the present one. Collins[2] described the case of a child, aged 1¾ years, which had separate tumours in the two orbits. Death ensued; and microscopical examination showed them to resemble lymphatic gland tissue, and there were deposits of a similar character which had not been discovered during life in most of the organs of the body. There was no enlargement of the external lymphatic glands, although those of the chest and abdomen were extensively involved. He referred to five similar cases in the literature, occurring at the ages respectively of 70, 57, 48, 33, and 4½ years, in addition to Silcock's case alluded to above.

Dr. G. A. SUTHERLAND and Mr. F. F. BURGHARD communicated a paper on two cases of Splenectomy for Splenic Anæmia, which will be published in THE LANCET.—Dr. F. DE HAVILLAND HALL described a case in which success had followed splenectomy.—Dr. H. D. ROLLESTON declared that his experience was that the operation had not been followed by success, and Sir A. PEARCE GOULD related the facts of a case of splenectomy with good recovery, the patient leaving hospital in excellent condition, but returned subsequently suffering from a plethoric condition, and died eventually from gastric and œsophageal hæmorrhage.

Dr. M. A. CASSIDY and Mr. C. M. PAGE demonstrated a method of determining the Absolute Pressure of the Cerebro-spinal Fluid.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Operations for Cancer of the Uterus.—Exhibition of Specimens.

A MEETING of this section was held on Dec. 1st, Dr. H. MACNAUGHTON-JONES being in the chair.

Dr. ARCHIBALD LEITCH read a paper on the Pathological Bases of Operations for Cancer of the Uterus. He considered that it was impossible to determine from clinical or histological examination the exact extent of cancerous disease in any given case. Hence it was justifiable to conclude that the only way of obtaining a radical extirpation of the disease was to apply to every case of cancer of the uterus a technique which was designed for the most advanced. Statistics had shown that 55 per cent. of cases were free from visceral or glandular metastases at the time of death, but these figures only applied to dissemination outside the pelvic cavity. Three lymphatic tracts were described: (1) to the inter-iliac glands; (2) to glands along branches of the internal iliac artery; and (3) to para-rectal glands. The last set were very rarely affected, in spite of the supposed frequency of invasion of the utero-sacral ligaments. The inter-iliac glands were the most important, and were in communication with another set on the outside of the common iliac artery. Both sets should be removed when there was evidence of glandular infection. Along the course of the ureter, through the broad ligament, lymphatic infection of the cellular tissue occurred, and by fibrotic contraction, as well as by direct invasion of its walls, the ureter became constricted, and hydronephrosis ensued in no less than 75 per cent. of all cases. Invasion of the vagina by cancer of the cervix occurred in all but 2·5 per cent. of cases; this was explained by the rich anastomosis of lymphatics between the cervix and upper segment of the vagina. Thus the excision of a wide cuff of vagina in Wertheim's operation removed a highly dangerous tissue. The bladder was involved in two-thirds of post-mortem cases, and the rectum in one quarter of the cases; while vesical perforation occurred in 44 per cent., and rectal perforation in 16 per cent. of cases. Free and timely removal of the upper segment of the vagina prevented the occurrence of these distressing and hopeless sequelæ.

Mr. C. P. CHILDE read a paper on Wertheim's Operation for Cancer of the Uterus. He based his remarks on 23 operations which he had performed. He had rejected no patient on account of age, the oldest operated upon being 65 years. The delay of patients in seeking advice was referred to, the average time from the onset of symptoms till patients came to operation being in his cases 9·4 months, and amongst those who had passed the menopause and in whom mistakes were therefore less excusable 9·2 months. Even amongst those who had applied within six months the disease had nearly always made considerable progress. He had had only one early case. After emphasising the necessity of examination under general anæsthesia and a microscopic confirmation of the nature of the growth in every case prior to operation, he next drew attention to the fact that in many advanced cases, especially in elderly women, the general health remained good. Some details and complications of the operation were illustrated by a reference to his cases. There had been one instance of ureteral fistula, due to wound of the ureter, which had been cured by subsequent lumbar nephrectomy. After alluding to implication of the bladder and rectum, he came to the important question of the routine removal of lymphatic glands, and condemned it on the following grounds:—(1) It must greatly prolong the operation and increase the primary risk; (2) inasmuch as glandular infection as a rule is late, the risk may frequently be added without any necessity for it; (3) as it is impossible to remove all the glands it is probably useless; and (4) where glandular infection has occurred, recurrence almost invariably takes place and life is not saved. Five patients had severe post-operative shock, none had died from it. He was of opinion that if cases were suitably selected, and the surgeon had had sufficient experience to perform the operation in a reasonable time, there was little to fear from shock. Sepsis was the most serious complication. It frequently attacked the abdominal wound, and primary union had only occurred in about one-half of his cases. Sepsis attacking the pelvic wound had accounted for the only two deaths in his series. His immediate mortality for all cases was 8·6 per cent. Mr. Childe finally contrasted the operation with vaginal hysterectomy in regard to its primary mortality and ultimate results. He thought the idea of the high primary mortality was exaggerated, and showed by a reference to his own cases and those of other operators that for like stages of the disease it was no higher than that of vaginal hysterectomy. It was the advanced cases which furnished the high mortality (about 20 per cent.), and these could not be attacked by the vagina at all. It was Wertheim's operation or nothing as far as radical treatment was concerned. For ultimate results, continental returns must be present be consulted, as the operation had not been performed long enough in this country to furnish the requisite data. By a reference to the work of many well-known continental operators, it was shown that there had resulted a percentage of cures and a prolongation of life such as the records of vaginal hysterectomy had not approached. In conclusion, Mr. Childe considered Wertheim's operation superior to vaginal hysterectomy in every particular for the following reasons: (1) It was exploratory in the first instance, and enabled the surgeon, after opening the abdomen, to decide with accuracy whether the case was suitable for radical treatment or not. 2. In cases comparable with vaginal hysterectomy its primary mortality was just as low. 3. It was a more scientific operation than vaginal hysterectomy, which was a shot in the dark. 4. It was on all fours with the more extensive operations for cancer elsewhere, which had been performed of late years, and which had given infinitely better results than the old partial operations. 5. There was evidence to show that it did give better results than vaginal hysterectomy. 6. If infected glands were present in early cases (though this was exceptional), it permitted of their removal. 7. It increased the percentage operability, and enabled more advanced cases to be dealt with. This he considered the least of its advantages. It was in the early cases that the good results were to be expected.—A good discussion ensued, to which the readers of the papers replied.

The following specimens were exhibited:—

Mr. J. D. BARRIS: Fibromyoma of the Uterus, which had caused acute obstruction of the small intestine.

Mr. DOUGLAS DREW: (1) Sarcoma of the Uterus; and (2) case of supposed Hermaphroditism.

Miss A. L. MCILROY: Hæmatosalpinx with Torsion of its Pedicle.

SECTION OF ANÆSTHETICS.

Hypnotism in Surgical Anæsthesia.

A MEETING of this section was held on Dec. 5th, Dr. W. J. MCCARDIE, the President, being in the chair.

Dr. EDWIN L. ASH read a paper on Hypnotism in Relation to Surgical Anæsthesia. The work of Dr. Esdaile, who served the old East India Company, he said, formed a starting-point from which to consider scientific work in this connexion. It was well known that he performed hundreds

[2] Reports of the Royal London Ophthalmic Hospital, vol. xiii., p. 248.

of operations on patients in the state of hypnosis in India. No one else had ever been able to repeat Esdaile's results. When a deep stage of hypnosis was obtained it afforded the condition of an ideal anæsthesia with no disagreeable preliminaries and no possible serious after-effects. But the difficulty was that the requisite state could only be induced in comparatively few people—roughly about 1 in 10 or 12. It was possible that some rapid, certain, and painless method of inducing deep hypnosis might some day be found, and then it was probable that this method would supersede all others for anæsthetic purposes. The theory of this process was obscure. Probably it was largely owing to concentration of the attention to some particular object or idea in the hypnotic state that consciousness to painful stimuli was lost. In hypnotic anæsthesia two factors have to be considered: 1. There was an "analgesia" due to the deep state *per se*. This was shown by blunting of perception to moderate stimuli—e.g., pin-pricks. But it was not protection against strong stimuli—e g., faradic brush. Therefore it was useless from a surgical point of view. 2. Anæsthesia produced by suggestion in the hypnotic state. This was reliable and to some extent controllable in satisfactory subjects. It was possible also to produce anæsthesia in some people who responded well to hypnotism by giving suggestions that were to bring about the required effect at some future date—that is, by post-hypnotic influence. This, again, was too uncertain to be of practical value in surgery. Consequently, the uncertainties and waste of time certain to ensue from attempting to make use of hypnotism for anæsthetic purposes placed it for the time being out of the range of practical politics. However, in the case of patients for whom a general anæsthetic was undesirable there was no reason why their suitability as subjects for hypnotic suggestion should not be tested some days before the date fixed for an operation. In any case, for urgent operations the method was quite inapplicable in the present state of our knowledge. Again, although hypnotism was so untrustworthy as an anæsthetic agent, there was a great field for the use of simple suggestion as an aid to anæsthetics. An arrangement by which a nervous patient about to be operated on could receive the benefits of "suggestion" for some time before the operation would unquestionably result in the anæsthetic being taken very much more satisfactorily than might otherwise be the case, and the advantages to the surgeon both during the operation and in the light of after-results would probably also be great.

Dr. C. LLOYD TUCKEY considered that to attempt to anæsthetise a person in an excited condition would in most cases be useless. Surgical anæsthesia had occasionally been produced by post-hypnotic suggestion alone, and suggestion without hypnotism was often sufficient to inhibit pain. He instanced an anæsthetist at a dental hospital who became very successful in gauging the susceptibility of persons to suggestion from their appearance, and could often produce anæsthesia in favourable cases by using an empty gas bag. Dentists had told him also that "Christian Scientists" could often stand the extraction of teeth without apparently feeling any pain. He considered that a "burly policeman" represented a type favourable to hypnosis.

Dr. S. H. NATHAN had also practised hypnotism fairly considerably. He found that the people who came to him to be hypnotised fell largely into two groups: first, highly neurotic individuals for whom hypnotism was a last resource; and secondly, persons who looked on it more or less as a joke. Neither of these groups represented favourable subjects. On one occasion when giving a demonstration on hypnotism he had seven cases from an institute for retired soldiers on whom to demonstrate. All seven were readily hypnotised. He considered that it was difficult to gauge accurately the degree of anæsthesia in a hypnotised person. A patient who had not responded to a pin-prick might shout out at an incision.

Dr. H. E. WINGFIELD had used hypnotism as an anæsthetic both in dental and confinement cases; in the latter it had certainly been of service. There were many curious and interesting points about hypnotic anæsthesia; general anæsthesia might be obtained or, when desired, one limb only might be rendered anæsthetic, rigidity appearing first and being followed by anæsthesia. A patient might be at the same time anæsthetic and hyperæsthetic in the same part; for instance, any *downward* touch on a limb might be unfelt, but the slightest *upward* touch be felt acutely.

The PRESIDENT discussed the question how far hypnotic suggestion might be used as an aid to ordinary anæsthesia—i.e., in diminishing after-effects, fear before an operation, or possibly enabling anæsthesia to be maintained with less anæsthetic, as in using morphia. He asked what was the effect of hypnosis as regarded the corneal reflex, the relaxation of the muscles, and the blood pressure.

Mrs. F. M. DICKINSON BERRY asked whether Dr. Ash considered that success or the reverse in hypnotism depended solely on the subject, or whether the hypnotiser was not also a factor.

Dr. ASH, in reply, said he thought suggestion should be a great aid to the anæsthetist, and the more suggestion the less chloroform. As regards after-effects, where they were due to toxic absorption, as was probably usually the case, they would not be affected by suggestion. Confidence in the result to be obtained on the part of the hypnotiser was certainly a factor in success, but beyond that he thought the hypnotiser was unimportant. There were certainly racial differences with regard to susceptibility to suggestion, black races being as a rule much more susceptible than white.

MEDICAL SOCIETY OF LONDON.

Acromegaly.

A MEETING of this society was held on Dec. 12th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. DAVID FERRIER, in the course of a paper on the Pathology of Acromegaly, said that in spite of all that had been written the points of agreement with reference to the pathology of acromegaly were still comparatively few, and that the more he studied the subject the more obscure it seemed to become. Acromegaly occurred most commonly about the period of adolescence and affected both sexes about equally. It varied in duration from a few years to 30 or more. The onset was insidious and the disease might exist for many years before its true nature was recognised either by the victim himself or his friends. The patient complained at first of various subjective symptoms, such as headache, pains and paræsthesia of the limbs, and general malaise. Sooner or later the characteristic changes became manifest in the head, hands, and feet. The hands became enlarged, the increased dimensions being due mainly to the skin and cutaneous tissues. Sometimes there was an increase in length, but more commonly the increase was in width, and the hands assumed a spade-like or battledore appearance. They were firm in consistence, the cutaneous folds exaggerated, and the fingers straight, and as large at the tips as at the base, constituting the so-called sausage-fingers. The enlargement did not usually extend beyond the wrist, so that it was all the more striking by comparison with the normal forearm. The feet were similarly affected; they were thickened, flattened, and the ridges and furrows markedly accentuated. The head was enlarged, and all the normal tuberosities and muscular attachments exaggerated, coarse, and rough. The face was oval, the forehead low and apparently receding, the orbits were thickened, the frontal and maxillary sinuses enlarged, and the zygomatic arches prominent. The body of the lower jaw in particular was hypertrophied, and the alveolar border extended beyond that of the upper jaw, constituting decided prognathism. The features were coarse, the nose, lips, and ears thickened, and the tongue over-filled the mouth, and tended to protrude between the teeth. The mucous membranes of the nose, pharynx, and larynx were redundant, and the voice was husky or hoarse. The neck was thick, and there was generally kyphosis in the upper dorsal region, and a tendency to protrusion of the lower end of the sternum, so that a Punch-like figure was developed. Vision was frequently impaired, more especially in the form of bi-temporal hemianopsy. Exophthalmos was common, and there might be ptosis or some other form of oculo-motor paralysis. The appearance of strength was illusory. The muscles were feeble and often wasted. The heart was weak and might be irregular, and there was a tendency to pant on exertion. Polydipsia and polyuria were common, and glycosuria had been observed in a large number of cases. Often there was a great tendency to somnolence. Impotence in the male and amenorrhœa in the female were the rule. The changes in the soft parts were largely due to hyperplasia of the connective tissues, and in the osseous skeleton to an exaggeration of the normal bosses, tuberosities, and roughnesses

which formed the points of the musculo-tendinous attachments. The periosteum was thickened. Osteophytes were common, and the vascular canals were numerous and dilated. The forms of enlargement of the pituitary body that had been found had been variously described as hyperplasia, adenoma, colloid degeneration, sarcoma, glioma, carcinoma, teratoma, and many others; but there was reason to believe that there had been great laxity in the nomenclature employed by different observers. The pituitary body was a small reddish mass, about ½ gramme or 7–8 grains in weight, filling the sella turcica, and attached to the infundibulum through a small opening of the pouch of dura mater in which it was enclosed. It consisted of two lobes, the anterior, somewhat bean-shaped, and the posterior, which fitted into the concavity of the anterior. The anterior was developmentally a diverticulum (Rathke's pouch) of the buccal ectoderm. That in time became constricted from the oral cavity by the development of the base of the skull, and the canal usually became obliterated. In certain cases, however, it remained patent, and formed the cranio-pharyngeal canal. It had been stated by Levi[1] that that was frequently, if not constantly, present in acromegaly and giantism, indicating that the basis of those conditions was probably laid down at a very early period of development, before the cranio-pharyngeal canal had become closed. At the pharyngeal end of that canal Erdheim, Haberfelt, and others had demonstrated the presence throughout life of a glandular structure similar to the anterior lobe of the pituitary and probably performing the same functions, and liable to the same diseases as the anterior lobe of the pituitary body itself. The existence of that pharyngeal pituitary body might perhaps explain some of the difficulties which had arisen in regard to the pathological findings. The anterior lobe was composed of epithelial cells arranged in trabeculæ, and surrounded by a rich network of thin-walled capillaries and lymphatics. The cells were of two kinds—chromophile and chromophobe—the former staining either with eosin or the basic dyes, the latter not. Intermediate forms were also described, but it was probable that they were not really different, but only different physiological conditions of the same cells. The posterior lobe was developmentally an evagination of that part of the embryonic brain which ultimately became the third ventricle. The cavity became obliterated in man, though in some animals, such as the cat, it remained patent. The posterior lobe was composed of connective tissue and neuroglia, but contained no true nerve cells. Between the anterior and posterior lobes there was a cleft, the remains of the original buccal diverticulum. The part of the posterior lobe adjacent to that cleft was covered by a special epithelium; it was called the pars intermedia. The cells of that epithelial layer somewhat resembled those of the anterior lobe, but they were less distinctly granular and were arranged in islets or nests, many of which were hollowed out and filled with a colloid-looking material. That colloid material was supposed by some to be the secretion of the pituitary cells, though the views were somewhat divergent on that point. It was assumed that the secretion of the anterior lobe passed directly into the blood-vessels, while that of the pars intermedia found its way through the posterior lobe into the third ventricle. Extirpation experiments had been carried out by various experimenters and on different animals and with most discordant results. Those were, no doubt, largely explicable by the differences in method and extent of the lesions that had been established. The symptoms resulting from complete removal of the pituitary body had been described under the name of cachexia hypophyseopriva. The chief symptoms of that condition were a lowered temperature, fall of blood pressure, spasmodic twitchings, and a peculiar arching of the back; the animal became lethargic, and ultimately passed into a state of deep coma. It had, however, been shown by Cushing and his colleagues, and his observations had been confirmed by Biedl, that the removal of the posterior lobe of the pituitary body caused no obvious ill-results. Complete removal of the anterior lobe alone, however, produced the same effects as the removal of the whole gland. Partial destruction of the anterior lobe in young dogs led to results of great importance in reference to a certain symptom-complex (Frohlich's syndrome) not infrequently observed in man in connexion with pituitary tumours. There was an increase of fat, which in some cases amounted to adipositas universalis, hypoplasia of the generative glands, and loss or diminution of sexual power. With that there was a condition of infantilism and retardation of development. Occasionally, also, there were polyuria, polydipsia, glycosuria, and falling out of the hair.

Dr. A. KEITH gave a lantern demonstration of the Features and Modes of Development of the Skeletal Abnormalities which characterise Acromegaly.

A short discussion followed, in which Dr. A. MACPHAIL, Mr. J. E. S. FRAZER, Dr. ROBERT JONES, and Dr. R. H. SCANES SPICER took part.

[1] L'Encéphale, May 10th, 1910.

HARVEIAN SOCIETY OF LONDON.

Treatment of Syphilis.

A MEETING of this society was held on Dec. 8th, Dr. M. HANDFIELD-JONES, the President, being in the chair.

Mr. J. ERNEST LANE read a paper on the Treatment of Syphilis, restricting his remarks to the position occupied by the arsenical compounds, atoxyl, arsacetin, soamin, orsudan, and the more recently introduced "606." Whilst admitting their undoubted value, he recalled the fact that irremediable blindness had followed the use of some of them, which had led him to abandon them. Speaking of "606" he deprecated the advertisement it had received in the lay press. He referred to the excellent results obtained with it by Professor Wechselmann, from whose description in the journals it might be imagined we had arrived at a new epoch in medicine. But there was another side to the picture. He thought that enthusiasts had greatly minimised the pain produced by the injection. Ehrlich himself now admitted that there were many conditions in which the employment of "606" was inadvisable. Two cases of blindness had been recorded and two others hinted at. Twelve deaths following its use were incontestable. Early recurrences of symptoms were frequent, and the drug had not been long enough in use for anyone to speak positively on the question of late recurrences. He had submitted some of his own cases to injection by Sir Almroth Wright and Mr. J. E. R. McDonagh. The results were in the main favourable so far as he could judge in so short a time, but no better than he would have expected from mercurial treatment. One case of syphilitic ulceration improved temporarily, but soon relapsed; another injection was given, followed again by improvement and other relapse, the ulceration spreading to twice its former size. The condition was now improving on intramuscular injections of grey oil. This case had been somewhat prematurely recorded in THE LANCET as one of the successes of "606." Another case was malignant syphilis which had resisted mercury and receiving no benefit from "606" ultimately died some ten weeks after the injection. Other cases were mentioned in which improvement was not particularly satisfactory, although the Wassermann test became negative. He showed a chart in which the temperature went up to 104°F. after the injection, and hyperpyrexia was present every evening for ten days following. Of his 17 cases five certainly called for no enthusiasm. Syphilis was a mild disease, generally perfectly amenable to mercury; intolerance of that drug was rare, and would be the only justification for looking elsewhere for a remedy. In appropriate cases "606" was a valuable addition to our therapeutical stock. Laboratory research in syphilis, as in other diseases, was of great importance, but should not replace the results of clinical experience.

Dr. W. D'ESTE EMERY then gave a brief outline of some of the modern ideas on the Pathology of Syphilis, dealing especially with the nature of the spirochæta pallida, the processes which took place in the body during the disease, and the question of immunity thereto. He dealt especially with the Wassermann reaction, claiming for his own modification the advantages of rapidity and accuracy. He urged particularly the importance of testing all cases quantitatively, and recommended the method of using various dilutions of a standard antigen, so as to determine the weakest by which the complement is completely absorbed. He also vindicated the use of methods depending on the absorption of the natural complement pre-existing in the blood, basing his experience on a study of over 500 sera. He believed that when a quantitative method was used and interpreted in the

light of the clinical history the percentage of error was extremely small.

Sir ALMROTH WRIGHT dealt with the matter from the laboratory standpoint. He considered that "606" undoubtedly caused the disappearance of the spirochæte and therefore cured syphilis, clinical manifestations to the contrary notwithstanding; these he thought were probably due to a secondary streptococcal or staphylococcal infection. He suggested that surgeons had a convenient conscience which allowed them to perform operations with a well-ascertained and sometimes high mortality but which did not justify their employing this remedy with its infinitesimal risks.

Mr. ARTHUR SHILLITOE related some remarkably successful results from the use of "606" in his practice.

Mr. CAMPBELL WILLIAMS drew attention to three deaths following the injection of "606" additional to the 12 mentioned by Mr. Lane, gave cases within his experience in which relapses had occurred, and criticised the so-called chemical constitution of "606." In view of the risks attaching to its use, he suggested a form to be signed by the patient for the surgeon's protection. Many of the cases reported as having been cured by "606" were nervous affections generally regarded as para-syphilitic, and on which theoretically it should have no action. If it were ultimately found to have this specific action they would have to alter their views as to their pathology.

Mr. LANE, in his reply, argued that there was no analogy between an operation performed for the cure of a serious, and possibly fatal, disease and the treatment of the mild type of syphilis present in this country.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Municipal Control of Pulmonary Tuberculosis.

A MEETING of this society was held on Dec. 9th, Dr. J. F. J. SYKES, Vice-President, being in the chair.

Dr. WILLIAM ROBERTSON, medical officer of health of Leith, introduced a discussion upon the Municipal Control of Pulmonary Tuberculosis. After stating that Leith had followed Brighton in adopting the principle of utilising disused wards at an isolation hospital for the treatment of phthisis, he expressed the opinion that every sanitary authority ought to adopt some scheme for dealing with the disease, and that neglect to employ some form of administrative machinery was evidence of a lack of appreciation of present-day hygiene. He then reviewed the advantages of compulsory as opposed to voluntary notification of phthisis. In Scotland sanitary authorities were empowered to make the disease notifiable, but they must first prove to the satisfaction of the Scottish Local Government Board that active steps would be taken to supplement notification. This implied the appointment of a special staff and the reservation of beds for the treatment of late or early cases. He considered that the best form of notification should be framed on the lines of the Sheffield sections with an additional provision requiring removal of cases which the medical officer of health considered were unsuitably housed or where precautions advised were not being adopted. In Leith, where compulsory notification is in force, those cases only were visited opposite whose names there were no stipulations made as to visitation, &c. There were now treated in an idle pavilion of the Leith isolation hospital about 20 patients. Advanced cases were not accepted, and every case notified for removal was examined by the medical officer of health or his assistant so that a standard of suitability had been established. Occasionally patients had been retained for nearly a year, but in the interval they had been taught to be useful members of the hospital staff. The average period of residence was three months, and this, especially with the very early cases, proved ample. In connexion with advanced cases which remained at home the contacts were sometimes received in the hospital for out-door treatment. The pale-faced children of consumptive parents were those selected for residence in the open-air ward. No patient was allowed to be idle. In Dr. Robertson's opinion, if phthisical patients are permitted to idle about they develop into perfect nuisances, and one grumbler will exert a most pernicious influence over his fellow patients. The men saw wood, do odds and ends at painting, assist the gardeners in digging and weeding. Each week one man is detailed to look after the meals. The women sew, weed the garden, keep the bungalow clean, and assist in the ward kitchen.

Some lantern slides were shown, among which was one depicting four disused tramway cars which were used as shelters in the grounds of the Leith hospital.

In the discussion which followed Dr. SIDNEY DAVIES said that notification of phthisis should be invited and not compelled. At Woolwich he had had double the number of cases notified since he had been able to offer sanatorium treatment. He emphasised the importance of providing work for patients after they had left the sanatorium.

Dr. J. E. SANDILANDS maintained that no municipal machinery for dealing with tuberculosis could be considered complete unless a tuberculosis dispensary were provided. The medical man who carried out the dispensary treatment should give his whole time to the work and should follow up the cases in the homes of the patients.

Dr. R. DUDFIELD considered that the real need for sanatorium treatment was not yet known and that dispensaries might make sanatoriums unnecessary.

Mr. E. H. T. NASH looked upon voluntary notification as a farce, and thought that from the point of view of the great cost involved sanatorium treatment was not justified. He advocated the establishment of dispensaries in which tuberculin treatment could be carried out.

Dr. WILLIAM BUTLER referred to the importance of increasing the resisting powers of the people by improved hygienic surroundings.

Dr. A. H. BYGOTT advocated greater coöperation between the Poor-law and public health services, and pointed out that boards of guardians never supervised the sanitary conditions of those to whom out-relief was given.

Dr. W. CAMAC WILKINSON considered that until tuberculin treatment was systematically used in dispensaries these institutions would not be so successful as they should be.

Dr. W. H. SYMONS urged the importance of securing the early treatment of patients.

Dr. A. MEARNS FRASER pointed out that as there seemed to be some doubt as to the power possessed by a municipality to spend money on a dispensary, any apparent illegality could be removed by putting a bed in the institution and calling it a hospital.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases and Specimens.—Pathogeny of Eclampsia.

A PATHOLOGICAL meeting of this institution was held on Dec. 1st, Dr. T. R. BRADSHAW, the President, being in the chair.

Dr. EDGAR STEVENSON showed five cases of Melanotic Sarcoma of the Choroid which had occurred in his practice within 12 months. The eyes, beautifully mounted by Mr. Harcourt, demonstrated the various stages to the fourth stage, involving the orbital tissues.

Dr. K. A. GROSSMANN showed a Melanotic Sarcoma of the Ciliary Region; and Dr. C. LEE a similar tumour of the eye.

Mr. W. THELWALL THOMAS and Dr. R. S. TAYLOR showed: 1. The Right Lobe of the Thyroid Gland removed from a man, aged 37 years, with severe Graves's disease. The mass weighed 6 ounces and had the usual microscopical appearances. The symptoms greatly improved in three weeks. 2. An Adenoma of the Thyroid from a girl aged 17 years. Microscopically it was very cellular and resembled an immature or fœtal thyroid tissue.

Dr. A. STOOKES showed a Uterus with Adeno-carcinoma of the Body, Interstitial and Submucous Fibroid; also a Uterus with Adeno-carcinoma of the Body simulating a Fibroid.

Mr. ARTHUR EVANS and Dr. P. HICK showed an Epithelioma of the Arm, which had arisen after a slight injury in the substance of the triceps muscle apparently from an epithelial cell-rest or dermoid. Prickle cells were demonstrated in the growth. The arm was amputated; there were no growths elsewhere.

Dr. J. M. HUNT and Mr. R. E. KELLY showed a Tuberculous Larynx in an infant, aged 21 months, with tubercle in both lungs and cavities at both apices. The parents were healthy and the child was breast-fed.

Mr. KELLY showed a specimen illustrating the association of Appendicitis and Undescended Testis on the same side. It illustrated the difficulty in diagnosis between

torsion of the undescended testis and appendicitis. Microscopically the appendix somewhat resembled mucoid cancer.

Mr. R. CRAIG DUN and Dr. ERNEST GLYNN showed a Malignant Tumour of the Right Suprarenal Gland removed post mortem from a girl, aged 5 years. The child showed marked precocity of development, her appearance being that of a girl of 15 years. There was profuse growth of hair on the scalp, upper lip, and pubes.

Mr. K. W. MONSARRAT and Dr. GLYNN showed Metastases of Lympho-sarcoma in both Suprarenal Glands secondary to growth in the Mediastinum.

Dr. GLYNN showed lantern slides of two cases of Multiple Myeloma in which the growth was of the plasma-cell type.

Dr. N. P. MARSH, Dr. J. CUTHBERT MATTHEWS, and Dr. T. J. WILLIAMS showed Blood Films from two girls, aged 3 and 10 years respectively, who had died from acute lymphoid leukæmia of the small lymphoid-cell variety. There was general enlargement of the glands. They both died within eight weeks of the onset of symptoms.

Mr. G. P. NEWBOLT and Dr. D. MOORE ALEXANDER showed a Tumour of the Brain excised from the right Rolandic area with temporary improvement. Death took place from recurrence. Dr. Alexander thought the growth resembled a neurocytoma, as described by Homer Wright.—Dr. GLYNN regarded it as a glioma sarcomatosum.

Mr. NEWBOLT and Dr. ALEXANDER also showed sections of Acinar Carcinoma in a woman, aged 38 years, and of Fibro-cysto-adenoma of seven years' history; and a painting of Malignant Pustule successfully treated by excision, local injections of carbolic acid, and intravenous injections of Sclavo's serum.

The PRESIDENT showed a specimen of Cerebral Hæmorrhage associated with Granular Kidneys and Hypertrophied Heart in a girl, aged 20 years. She had suffered from headaches for a year. He also showed a specimen of Hæmorrhage into the left lateral lobe of the Cerebellum in which there were no paralysis, contracted pupils, and a temperature of 105° F. The pons was normal; there was no blood in the fourth ventricle. There had only been one case of cerebellar hæmorrhage in the records of 1800 necropsies at the Infirmary in 14 years.

Dr. H. LEITH MURRAY read a paper on Some Points in the Pathogeny of Eclampsia. As the result of microscopical examination he considered the toxin to be one containing hæmolytic (cytolytic), hæmagglutinative and endotheliolytic elements, and pointed out how a polymorphism of the lesion was produced by interaction of these. He admitted a difficulty in deciding to what extent the lesions in the central nervous system were due to direct intoxication (neurotoxin) or to vascular disturbances. Certain experimental and natural conditions were compared with eclampsia: (1) the lesions produced by the inoculation of certain immune sera; and (2) the lesions and effects on the circulation produced by snake poisoning. The extraordinary similarity in type of toxin between this latter and the eclamptic was detailed, and the variety of such toxin was emphasised. Evidence was adduced that this comparison was no mere artificial one in the results. Burgers had lately demonstrated the presence in maternal serum of a cobra-hæmolysin-inhibiting factor. Dr. Leith Murray had confirmed this in several cases, but had found it absent in a case of eclampsia. Further results were promised later. He suggested the experimental use of Calmette's antivenene in eclampsia, injecting it subcutaneously in the pre-eclamptic stage and intravenously in the eclamptic stage. The injections could do no harm—The PRESIDENT congratulated Dr. Leith Murray on his interesting and original paper. He thought that an appropriate serum might be found for puerperal eclampsia; but doubted whether antivenene was likely to be useful. The various venoms were much more closely related to each other than any of them were to the toxins causing eclampsia, and yet these antisera were practically useless against any but their own particular venom. The action of venom neurotoxin was always paralytic and that of eclampsia was for the most part convulsivant.—Dr. W. BLAIR BELL said that there was little doubt that whatever the primary cause of eclampsia was, the ultimate results in fatal cases were due to the establishment of a secondary vicious circle whereby the changes in the liver led to an intoxication of the patient by the products of its disintegration. He did not think it likely that antivenene would prove specific, but he was much impressed by Dr. Murray's interesting arguments in favour of the serum.—Dr. STOOKES, Dr. GEMMELL, and Dr. GLYNN also spoke.

Exhibition of Cases.—Liquid Air and Carbon Dioxide Snow in the Treatment of Skin Diseases.

A MEETING of this society was held on Dec. 8th, Dr. T. R. BRADSHAW, the President, being in the chair.

The PRESIDENT showed two patients the subjects of Congenital Heart Disease: 1. A woman, aged 38 years, married 15 years and with three healthy children. Cyanosis had been present since infancy. There were also clubbing of the fingers, polycythæmia, and a systolic murmur over the ventricles. The heart was not much enlarged and the patient enjoyed fairly good health. 2. A youth, aged 17 years. There was no cyanosis, but dyspnœa on exertion. The heart was much enlarged and a rough systolic murmur and thrill were heard over the pulmonary area.

Dr. NATHAN RAW showed: (1) A case of Graves's Disease much benefited by rodagen treatment; (2) a patient with Diabetes Mellitus, Tabes, and Double Perforating Ulcers; and (3) a patient with Traumatic Hemiplegia and Aphasia, with total destruction of the left motor area and Broca's convolution.

Dr. A. GORDON GULLAN showed a child, aged 3 years, suffering from Various Hæmorrhages from the Mucous Membranes and Kidneys. The child had been fed upon tea, bread and butter. Dr. Gullan considered the case to be one of scurvy rickets.

Dr. G. G. STOPFORD TAYLOR and Dr. R. W. MACKENNA, amongst other cases, showed a patient with Bronzed Diabetes, and a case of Primary Chancre with Secondary Eruptions. Within a week after one injection with "606" these signs had disappeared

Dr. STOPFORD TAYLOR and Dr. MACKENNA communicated a paper on Liquid Air and Carbon Dioxide Snow in the Treatment of Skin Diseases. They had used these agents with much advantage for over three years. Liquid air was approximately two and a-half times colder than carbon dioxide snow. It was easily applied on a piece of cotton wool twisted round a cane, and the application should be of a shorter duration than the snow. The drawbacks to its use were its cost and the fact that it evaporated very quickly. The snow, on the other hand, was easily procurable and cheap, and the pencils of the snow were easily prepared and applied. They had designed a series of moulds at a trifling cost. The application of either the air or the snow was not very painful except near some superficial nerve, or over a bone, carious teeth, or on the ears. The therapeutic use depended upon the reaction, which varied according to the nature of the tissue, the duration of the application, and the pressure applied. The reaction consisted in the copious outporing of serum with the formation of a bulla; there was marked diapedesis of leucocytes, the connective tissue becoming swollen and enlarged; many of the capillaries became thrombosed, but the epithelium sustained the chief damage in that in most cases it was completely destroyed. The after-treatment was simple. The bulla might be left unbroken for a few days and then clipped off and the resulting raw surface dressed with some simple dressing. Healing was somewhat slow but restitution was complete and sometimes surprising. Dr. Taylor and Dr. MacKenna gave their experience in the treatment of nævi, moles, X ray warts, lupus erythematosus, rosacea, and lupus vulgaris. Their best results in lupus vulgaris were obtained by linear scarification followed in a day or two by refrigeration with snow. Refrigeration should not be used in old people or in those suffering from broken-down constitutions or from arterio-sclerosis or nephritis. The paper was illustrated by lantern slides and the exhibition of patients and a practical demonstration of the methods of application.—Dr. W. C. Oram mentioned a case of Nævus of the Upper Lip in a child, aged 3 months, which had been much improved by the application of the snow; the child did not seem to suffer much discomfort.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 2nd, Dr. Phineas S. Abraham, the President, being in the chair.—Mr. J. E. R. McDonagh read a paper on Practical Experience with Ehrlich's New Specific for Syphilis. He commenced by

stating how Ehrlich came to discover "606," and then went on to say that as atoxyl and arsacetin produced amaurosis, it was feared that "606" might do the same, but since more than 20,000 injections had been given without this occurring, and since the drug seldom gave rise to toxic symptoms, its general employment had been considered absolutely safe. Although the intramuscular route was at first very largely employed, there was absolutely no doubt that the intravenous method was preferable. The patient suffered only a slight inconvenience in the form of a rigor or two and vomiting a few hours after the injection, compared with the severe pain which the intramuscular injection gave rise to. Of still greater importance was the fact that the organisms were killed at once, whilst with an intramuscular injection the absorption was slow and some of the arsenic might become completely encapsuled, thereby increasing the risk of a second injection, should it be necessary, owing to the fact that the encapsuled arsenic might at any time become liberated and with the arsenic given at the second injection amount to a toxic dose. The best method of procedure was to give an intravenous injection, and if the symptoms did not show marked improvement by the end of the third day an intramuscular injection should then be given. If the lesions improved, one should wait for about four weeks to be guided by a Wassermann's reaction as to whether a second injection (intramuscular) was necessary or not. Cases were described of sleeping sickness, tuberculous forms of leprosy and leukæmia, psoriasis, and lichen planus in which "606" had exerted some beneficial action. Other infections superadded on syphilis, such as tubercle, streptococci, and staphylococci, were often markedly improved by "606." A case was shown in which extensive phagedæna had been checked by one injection. Several cases were shown illustrating the cure produced in all the stages of syphilis. A case of lichen syphliticus, the most resistant form to mercury, was cured by one injection of "606" without any scars resulting. Malignant cases of syphilis associated with tuberculosis were improved beyond recognition. The most striking cases were those who had suffered nerve paralysis from syphilitic meningitis. Almost complete power in the muscles supplied by these nerves had been regained. One case of tabes was cited, in which both the Argyll Robertson pupil had disappeared and the knee-jerks returned, and also morning erections which the patient had not had for four years. Seventeen cases of tabes had been injected, but only three improved insomuch as the lighting pains had disappeared. Cases of general paralysis of the insane before degeneration had commenced improved considerably. Chronic superficial glossitis, which hardly ever responded to mercury, was greatly benefited by "606." In all, Mr. McDonagh had treated 130 cases, three of which had recurred, two of these being cured by a second injection, and five only did not respond to "606."—Dr. Abraham regarded this method as the most important advance in the treatment of syphilis. He called attention to the smallness of the scars as compared with those following the ordinary methods of treatment.—Mr. Arthur Shillitoe drew attention to the difficulty in diagnosing syphilis by the Wassermann reaction owing to varying results given when different techniques were employed.—Captain L. W. Harrison, R.A.M.C., said that "606" had been used at the Rochester Row Military Hospital for some months, and was given by intravenous injection, using an ordinary transfusion apparatus with a short pointed needle. A second injection was given when the clinical signs did not disappear sufficiently rapidly or when the Wassermann reaction remained positive after three or four weeks.—Mr. H. W. Bayly said the permanency of cure by "606" had yet to be established and the evidence of the Wassermann reaction was very conflicting.—Mr. R. B. Etherington-Smith said that Mr. McDonagh had given injections of "606" to several cases of his and the immediate results had been wonderful, notably so in one of gummatous meningitis of ten years' standing.—Mr. Aslett Baldwin and Dr. T. Grainger Stewart also discussed the treatment.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 1st, Dr. F. Hinds, the President, being in the chair.—The following resolution was carried unanimously:—

That this society earnestly requests the town councils of Brighton and Hove to pass and enforce a by-law against spitting on the pavement, and to take steps to lessen the great and insanitary nuisance caused by dogs on the public footpaths.

—Dr. E. Weatherhead showed a case of Ossifying Enchondroma growing from the second cervical vertebra in a woman aged 49 years. It was first noticed when the patient was 9 years old, and had reached its present size at about the age of 25 years, since when it had ceased to grow. There was a very large, painless tumour at the back of the neck which caused but little inconvenience beyond slightly restricting movement of the neck. An X ray photograph, taken by Dr. C. F. Bailey, showed well the structure of the growth.—Dr. H. Galt showed a photograph, taken a week before death, and a section of one of the glandular masses in the neck, from a case of Hodgkin's Disease in a boy aged 10 years. The section showed characteristic appearances—viz., almost complete destruction of the normal lymphoid tissue, and its replacement by an endothelial proliferation within a fine reticular stroma. Several large "lymphadenoma cells" were also seen. The capsule of the gland was intact. Dr. Galt in addition showed a small Ovarian Dermoid Cyst removed by Mr. H. Nethersole Fletcher from a woman aged 24 years. It contained five teeth, numerous hairs, and the usual buttery material. The surface was lined with squamous epithelium, and beneath this were numerous sebaceous glands and hair follicles, but no ovarian tissue.—Dr. E. R. Hunt read notes of a case of Recurrent Carcinoma of the Parotid Gland treated with Coley's fluid. The patient was a man, aged 54 years, who had a large malignant growth on the right side of the neck, apparently originating from the parotid gland. Twenty-five years ago he had been operated on for a growth in the neck, which had recurred 12 years later. It had slowly become larger and more painful, and was now quite inoperable. Injections of Coley's fluid were given, and as the result of these the greater portion of the growth had sloughed and the pain and pressure symptoms were relieved. The patient had a peaceful end.—Dr. A. W. Williams read notes of a case of Gonorrhœal Keratosic Cones of the Feet and Hands. He said it was a very rare condition and only occurred in cases in which there was other evidence of gonococcal septicæmia, such as arthritis or tendo-vaginitis. It showed itself in two forms, both of which were present in this case: (1) diffuse thickening of the horny layer of the foot, and (2) the development of transparent horny cones and domes, mostly on the hands and feet, but sometimes in other places. Most of the cases are recorded in continental literature, probably because foreign dermatologists often include gonorrhœa in their specialty. The history of the present case was as follows. He was an in-patient at the Sussex County Hospital under the care of Dr. E. Hobhouse, suffering from gonorrhœal arthritis. Whilst undergoing treatment he developed the peculiar condition of the skin referred to. No gonococci were found in cultures from the greyish putty-like material found under some of the horny masses.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 24th, Dr. Samson Mathews, Vice-President, being in the chair.—Dr. A. E. Naish, in a paper on the First Month of Infancy, pointed out that it was common knowledge that infants were weaned unnecessarily, but owing to a lack of an intimate knowledge of the causes which led to it the custom was still prevalent. Depressed and fissured nipples or chronic mastitis were not necessarily a contra-indication to breast-feeding. In the infant, crying, vomiting, and wasting were the usual reasons given for weaning. He showed that any of these symptoms might be fallacious, and that it was especially important in a wasting child to ascertain whether this condition was due to a defect of the milk or not. In the latter case the wasting was usually aggravated. He showed that the influence of the nurse was often against the continuance of breast-feeding and that many arguments she used were fallacious. In referring to cases of so-called congenital atelectasis, he brought forward examples where the infants were at first strong and healthy and in whom the onset of the symptoms dated from the fifth or sixth week. Such cases seemed to have a familial incidence. He thought that in these cases the collapsed lung was probably not present from birth and that possibly the disease might be a disorder of the normal respiratory reflex.—Mr. Graham S. Simpson showed specimens and read notes of three cases of Nephrectomy. 1. Suppurating Hydronephrosis from a woman aged 55 years. Pus could be seen coming from the right ureter. Skiagraphy showed two shadows in the right kidney region; a diagnosis of calculous pyonephrosis was made. No stones, however, were found on excision. 2. A small Fatty

Kidney, containing a calculus, from a boy aged 16 years. He was admitted to hospital for flexion of the left hip and spine, but no psoas abscess could be felt. After he had been in a fortnight a large psoas abscess developed which was opened and drained. Two months later, as the patient did not improve, he was persuaded to have another operation when this kidney was found and removed. 3. A Tuberculous Kidney removed from a man aged 22 years. He complained of great frequency in micturition and pain in the right loin. There was intermittent pyuria but no tubercle bacilli were found in the urine. Skiagraphy showed a shadow just below an enlarged right kidney. Chromo-cystoscopy was difficult as the bladder bled easily, but the right ureter was watched for two minutes and no urine was seen to come out. The kidney was excised as it felt like a bag of pus. It contained numerous tuberculous abscesses but also a fair amount of kidney substance. The patient's output of urea was very small for the first few days; it then increased till about the eighth day, after which it rapidly fell. He died from uræmia a fortnight after the operation.—Dr. Stanley Riseley showed: 1. A man with a Corneal Ulcer due to an injury by a chipping of brass. 2. A girl with Marginal Blepharitis of old standing. All the lashes were now lost and there were opacities on both corneæ. 3. A case of Subacute Glaucoma with a chronic conjunctival discharge making it dangerous to operate. 4. A case of Trichiasis for which Arlt's operation had been done on both eyes.

Reviews and Notices of Books.

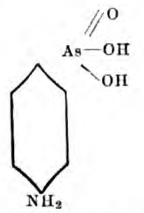
Die Experimentelle Chemotherapie der Spirillosen (Syphilis, Rückfallfieber, Hühnerspirillose, Frambösie). (Experiments in the Chemical Treatment of Spirillum Infections (Syphilis, Relapsing Fever, Fowl Spirillosis, Yaws)). By PAUL EHRLICH and S. HATA. Five plates. Berlin: Springer. 1910. Pp. viii.—164. Price 6 marks (6*s.*), paper; 7 marks (7*s.*), bound.

THIS little book, which is shortly to be published in English, gives a most instructive account of the researches which led to the announcement of "Ehrlich-Hata 606." In the first part Hata describes his investigations planned to determine the best therapeutic agent for destroying spirilla parasitic in the blood. They could only be attacked, as Ehrlich had shown, through their chemoceptors. Of these they have many, but in the present study only those receptors or chemoceptors came to be considered which manifested a great affinity for, a greater disposition to combine with, the radicals of the chemical substances (drugs) used than did the receptors of the tissues of the host. In other words, Hata was seeking for the treatment of these infections a drug which should attack the spirilla more energetically than it attacked the patient, should poison them rather than their victim. Accordingly, he endeavours for each animal, for each parasite, for each drug, to determine the ratio:—

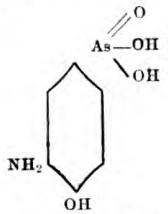
$$\frac{C}{T} = \frac{\text{curative dose}}{\text{tolerated dose}} = \frac{\text{dose sufficient to destroy all parasites.}}{\text{maximum dose which will not kill patient.}}$$

If a drug is to be of use in clinical medicine this ratio should be one-third or less, and this condition, it is claimed, has been thoroughly fulfilled by the dioxydiamidoarsenobenzol "606." Very oxidisable this is, Hata says, and therefore it is only sent out in exhausted glass tubes. Itself insoluble in water, its hydrochlorate does dissolve, giving a very acid solution, too acid to be injected. If to this normal caustic soda solution be added a precipitate will be thrown down, which may be separated by the centrifuge, and then, while still moist, it can be dissolved in a very little of the alkaline solution and is now fit to be injected.

In the second part of the book Ehrlich tells how he came to devise "606," why it has its power, and what he hopes it will achieve. Laveran had stated in 1903 that arsenious acid had an action upon trypanosomes, and in the same year Ehrlich and Shiga examined atoxyl, but set it aside as they found it had no action on trypanosomes *in vitro*. In 1905 Thomas and Breinl of the Liverpool School of Tropical Medicine reported that atoxyl had good therapeutic effect on trypanosome-infected animals. So Ehrlich took atoxyl up again, and with Bertheim found its chemical constitution had been misunderstood, and that it really was a paramidophenylarsenate:—



From this by oxidation, first with nitrous, then with nitric, acids, and by subsequent reduction, they obtained metamidoparaoxyphenylarsenate:—



As the arsenic here is five-valent the substance is not very poisonous. On the other hand, the large dose required to free mice from trypanosomes may suffice to cause destruction of the auditory and visual nuclei, so that the mice suffer from tremors and are named "dancing mice." Further reduction still, produces a molecule with trivalent arsenic uncombined with oxygen, more poisonous to spirilla, less hurtful to higher animals, and chemically more stable. This is the diamidodioxyarsenobenzol. The first of these arsenical preparations of Ehrlich to be used extensively was arsenophenylglycin in sleeping sickness. It is dangerous, but so is the disease. It should be given in one or two large doses, the highest the body can stand, so that it produces the maximum effect on the parasites before it has had time to damage the tissues of their host. A similar aim is before us in giving "606," which was introduced in June, 1909, as a remedy for relapsing fever; its effect on syphilis has only become known since. All arsenic preparations are toxic, but Ehrlich holds that in "606" this toxicity is held in check by the amido and hydroxyl groups in the molecule, and that this drug is as safe as mercury, and safer than grey oil. Its administration may cause severe pain (one man has died from shock), and it should not be given where a rise of blood pressure may do harm—e.g., in aneurysm and heart affections, nor in paralyses and optic atrophy; it clears up optic neuritis and renal affections of specific origin. It has been used in 10,000 cases without, it is said, any serious consequent complications, and the dose may go to 22 grains without danger. It produces, Ehrlich says, antibodies in the milk and serum of patients; it excites rapid absorption of syphilitic exudations and stimulates the growth of epithelium; and he recommends it for use specially in cases of malignant and ulcerating syphilis, in psoriasis palmaris, and in cases that cannot take mercury, or take it with little or no benefit. It produces its effect most rapidly when administered intravenously; this should be followed by a subcutaneous or intramuscular injection two days later. As it very rapidly heals mucous patches and ulcerations of the mouth, it will materially diminish in future the spread of the disease.

We do not give more space to this very original book, the English translation of which will be widely read, because our

columns have reported in full so many actual experiences of the treatment. The authors also report successful employment of "606" in relapsing fever in Cairo and yaws in New York.

Ehrlich has never asserted that the results of treatment by "606" were permanent, whatever may have been hoped, and since this book was published articles have appeared in Germany urging that ordinary cases of syphilis should be submitted to the usual mercurial routine with doses of "606" two or three times to accelerate the effects of treatment. From neither one nor the other, nor from both, can we at present promise a permanent cure. Yet Ehrlich and Hata deserve our gratitude, they have so enormously increased our power of dealing with this intractable disease.

Aspects of Death and their Effects on the Living, as Illustrated by Minor Works of Art, especially Medals, Engraved Gems, Jewels, &c. By F. PARKES WEBER, M.A., M.D. Cantab. London: T. Fisher Unwin. 1910. Pp. 160.

THE contemplation of death as a condition, state, or event, which will indubitably happen to everyone, has from the earliest times been a factor in human life. Not merely the fact, but the knowledge that death must come, has affected conduct, literature, and art more widely, perhaps, than anything else. Both those who believed in a future life and those who considered death as the end of all things have ruled their own lives, and those of their opponents when they were in a position to do so, from a consideration of death, for the appalling cruelties committed in the name of religion, when reduced to their common denominator, practically depend upon the fact that it was necessary to behave in a particular manner during this life, than which there was no other, or so to live here with a view to the conditions after death. The literature about or in connexion with death is endless. We need only here refer to two instances where both writers were medical men—namely, Henry Vaughan, in his poem "Friends Departed"; and Sir Thomas Browne, in his magnificent prose poem, entitled "Hydriotaphia." Another medical man, Dr. F. Parkes Weber, has now taken up the subject from a different point of view—namely, the consideration of death as exhibited in minor works of art.

Dr. Weber is known as an accomplished numismatist, and within quite a short space of time as the donor of a fine collection of medals to the British Museum; he is therefore able to treat his subject with the knowledge of an expert. The first part of the work is a general introduction to the whole matter; the second is an analysis of the various aspects of death, with the mental attitudes towards death, in order to show the headings under which the illustrative works of art may be grouped; the third part is devoted to the consideration of the medals and coins; and the fourth to gems and jewels. Dr. Weber has collected a wonderful amount of information, and the value of his book is much increased by the illustrations which he gives of coins, medals, gems, and pictures dealing with the matter in hand. On p. 14 he refers to the story of the "trois morts et les trois vifs." We might add to his examples the picture by Rossetti, entitled "How they Met Themselves," which has obviously the same meaning, although "themselves" are not represented as dead. On p. 41 he gives the inscription, "Mors sceptra ligonibus æquat," and its well known English equivalent by Shirley. Dr. Weber remarks that the quotation is ascribed to Lucan. We have been unable to trace it in the Pharsalia, the only poem of Lucan which has come down to us, but as the sentence occurred in a fourteenth-century wall painting it may have been quoted from Lucan's other poem on the burning of Rome, which is now lost. Claudian, however, in his "De Raptu Proserpinae," Book II., line 302, says, "Omnia mors aequat," which expresses a similar feeling, and we may also refer to the inscription on the tomb of Fair Rosamund:—

> "Hic jacet in tumulo Rosa mundi non Rosa munda:
> Non redolet sed olet quae redolere solet."

Sepulchral monuments designed to show the contrast between the dead and the living were common in the Middle Ages, and Dr. Weber gives an illustration of the well-known monument of Archbishop Chichele in Canterbury Cathedral. It is interesting to remember that something of the same idea is expressed in the only monument from old St. Paul's which survived the fire—we mean that of Dr. Donne, who is represented in his shroud. It is placed in the south choir aisle.

We are grateful to Dr. Weber for a painstaking and interesting piece of work, both from the literary and artistic point of view.

The Nutrition of the Infant. By RALPH VINCENT, M.D. Durh., M.R.C.P. Lond., Senior Physician to the Infants' Hospital, Westminster. Third edition. London: Baillière, Tindall, and Cox. 1910. Pp. 342. Price 10*s.* 6*d.* net.

OF all the numerous substitutes for the natural breast-feeding of infants, percentage or laboratory feeding is the one which is capable of the most careful and scientific adaptation to the needs of the infant. Its elaboration in America by Dr. T. M. Rotch was undoubtedly a notable contribution to the important subject of infant feeding. In this country, in spite of the ardent championship of Dr. Ralph Vincent, it has only been employed to a comparatively limited extent. In this book, which has now reached its third edition, Dr. Vincent gives a very interesting and lucid account of this method and of the principles upon which it is based.

He first discusses at considerable length the composition of human milk, giving the results of numerous analyses by different authorities, thus affording an approximate standard for comparisons. The management of the lactating woman is then considered, and general rules are given in regard to diet, exercise, and other conditions influencing the function of lactation. Cases are described illustrating the care and management of conditions of disordered lactation. The chemical composition of cow's milk is then studied and the differences between human and cow's milk are considered. The function of the extractives present in milk and the influence they exert upon nutrition are discussed.

In regard to substitutes for breast feeding, Dr. Vincen uses the term "substitute feeding" for wet-nursing and for modified cow's milk, restricting the term "artificial feeding" to those methods where food mixtures are made with products artificially prepared by manufacturers. He describes the methods of preparing percentage milks adapted to different ages and to different conditions. This method of feeding he describes as "combining clinical elasticity with scientific precision." While admitting its value, we must confess that the objections of its complexity and cost, which Dr. Vincent does not attempt to deny, seriously militate against its general adoption at present. The general question of the milk-supply is considered in a separate chapter, and an earnest plea is registered for milk commissions to ensure a pure milk-supply on the lines of those already in action in some American towns. A chapter is also devoted to the heating of milk and the changes induced by it. Boiling and sterilisation are strongly condemned, and Dr. Vincent states that he now uses unheated milk mixtures, simply warming to blood heat immediately before administration. He therefore emphasises the importance of securing good pure fresh milk. Other matters discussed are the chemistry of infantile digestion, the diet of the infant in relation to growth, and the effects of variations in the individual constituents of the diet. A

general consideration of the normal development of the infant, including its weight, muscular and nervous functions, the special senses, and dentition, is also given.

The remainder of the book is devoted to a study of the effects of errors of diet upon the digestion and nutrition of the infant. The various gastric and intestinal disorders are described and the appropriate treatment is set forth. Zymotic enteritis or infantile diarrhœa is dealt with at some length. Dr. Vincent maintains that an essential factor in the development of the disease is that the characteristic properties of the milk should have been destroyed by heat, by preservatives, or by some other means. Descriptions of infantile atrophy, of rickets, and of scurvy are given, and the prevention and treatment of these conditions are discussed.

Dr. Vincent's book is a thoughtful and practical work on the subject with which it deals. It abounds in useful information, and is obviously the outcome of special experience. Although some of his views will not find general acceptance, they demand consideration, since they are based upon a practical study of the principles involved. The book is written in an easy and readable manner.

LIBRARY TABLE.

Transactions of the American Dermatological Association at its Thirty-third Annual Meeting held in Philadelphia, June, 1909. Official report of the Proceedings, by GROVER W. WENDE, M.D, secretary. Pp. 289.—Much valuable work has been accomplished by American dermatologists, and some of the most interesting discoveries are usually reserved for the annual meeting of the Dermatological Association. This report of the proceedings of last year's meeting, which has just come to hand, contains so much that is new and important that it is difficult to pick out what is the most valuable content of this interesting volume. Three papers connected with psoriasis deserve mention. Dr. S. Pollitser has written on the etiology of the disease, Dr. J. F. Schamberg on the parasitism of psoriasis, and Dr. W. F. Breakey on some unusual cases of psoriasis. We agree with Dr. Pollitser's conclusions that psoriasis is most probably due to an external microbial infective agent. Dr. J. A. Fordyce's study on the lichen group of skin diseases will well repay perusal, and the admirable photoprints accompanying it can but enhance its value. Dr. H. H. Whitehouse has applied the Wassermann test in some cases of scleroderma, and he is inclined to suggest, from the fact that in the six cases in which the test was applied three gave a positive action, that syphilis may be found to be an etiological factor in the production of scleroderma. A very interesting paper is that written by Dr. Douglas W. Montgomery and Dr. Howard Morrow on the increase of certain contagions following the great fire in San Francisco. The chief contagious skin lesions were impetiginous in nature.

War, Police, and Watch Dogs. By Major E. H. RICHARDSON, late 45th Regiment (Sherwood Foresters), Fellow of the Zoological Society. Edinburgh and London: William Blackwood and Sons. 1910. Pp. 132. Price 5*s.* 3*d.* post free.—This book is an endeavour to bring before the public the value of certain services which the dog is fitted to perform for man. These include the tracking and arrest of criminals, a service in which dogs are now regularly used in Germany, the searching out of wounded soldiers on the field of battle, the carrying of messages and despatches, and the use of dogs as sentries and scouts. A chapter is devoted to the watch-dog in the house, and some useful information is given concerning the best methods of utilising a dog for this purpose. The foot of the staircase in the hall, as being probably the centre of the house, is recommended as the best position for the dog at night, where he should be chained up beside a comfortable bed placed there for him. The use of dogs in war for searching out the wounded seems justified by the results which followed the use of some of Major Richardson's dogs in the Russo-Japanese war. On this point Captain Persidsky writes as follows: "In finding the missing and wounded, with which the millet-fields are strewn, nothing has succeeded like our pack of seven dogs. The English ones are especially intelligent. In our last engagement 23 men were found in unsuspected places." Major Richardson recommends the collie and retriever as the breeds of dogs best suited to ambulance work in temperate climates. He is making a trial of bloodhounds for hot countries. Directions are given as to the training and equipment of dogs for ambulance work. The book concludes with a chapter on scent, in which is contained an account of some experiments performed by the author and others in an attempt to elucidate the nature of this faculty. Certain general conclusions are reached in regard to the best condition of soil and atmosphere for the preservation of scent, but it has not been possible to draw any particular conclusions or to dogmatise, and the subject remains much in the condition in which it was. The book contains much useful information of the practical sort.

The Building and Care of the Body. By COLUMBUS N. MILLARD. New York: The Macmillan Company. 1910. Pp. 235. Price 2*s.* 6*d.*—This is a fair example of the innumerable little works upon hygiene, both personal and general, which have of late years been conspicuous features of the semi-medical press. It is apparently written for both teachers and children, and not, we gather, for those of even a modest degree of education, for many words are given phonetically, as well as spelt in the ordinary way—thus, contraction (kŏn-trăk'shŭn). The book commences with simple lessons in physiology, and then goes on to treat of food, air, and the effects of pure and foul air on the health. Then follows a section on personal hygiene, common accidents, and contagious diseases. There is a glossary at the end. We cannot conscientiously say that the book is of much value.

JOURNALS AND MAGAZINES.

Journal of Pathology and Bacteriology. (Official Organ of the Pathological Society of Great Britain and Ireland.) Vol. XV., No. 1, containing 19 plates, one of them coloured. Published from the Department of Pathology, Cambridge University. Pp. 136. Price 7*s.* 6*d.* net.—In the current number of this journal M. A. Ruffer and A. R. Ferguson (Cairo), in a Note on an Eruption resembling that of Variola in the Skin of a Mummy of the Twentieth Dynasty (1200–1100 B.C.), describe and illustrate the results of a histological examination of an Egyptian mummy which showed a bullous eruption within the epidermis, as in small-pox, with many bacteria in the dermis. It is very interesting to note the extraordinary "keeping" powers of these bacteria, and even the tissues in which they are embedded. In Observations on the Changes produced in the Blood and Bone-marrow by Hæmorrhage and Blood Destruction, C. Price Jones (London) gives a description and classification of the marrow cells of the rabbit, tracing both the erythroblastic and leucoblastic series to a primitive lymphoid cell which, along with Buchanan, he derives by budding from the giant cells. By emulsifying the fresh marrow in 10 per cent. neutral glycerine films may be made; these are stained by Jenner's stain, and show many details which cannot be seen by section methods. The proportions of the different kinds of cells may be determined by counting these films. The marrow of rabbits, bled and killed after various intervals and examined, shows that this method brings

out well the erythroblastic reaction, and that when the nucleated red cells in the marrow are increased there is also an increase in the lymphoid cells from which they are derived. J. S. Dunn (Glasgow), in a paper on the Oxydase Reaction in Myeloid Tissues, demonstrates that the synthesis of indophenol from alpha-naphthol and dimethyl-paraphenylendiamin is produced by neutrophile and eosinophile leucocytes, and less rapidly by large hyaline leucocytes and by myelocytes in marrow and leukæmic blood. Mast-cells produce this less readily, as do some myeloblasts (non-granular myelocytes). The reaction is not given by lymphocytes or red blood cells, nor by normal tissue elements except the epithelium of the parotid and lacrymal glands. The oxydase in myeloid cells is not destroyed by the paraffin process; sections are best preserved in water-glass. It is soon destroyed by hydrochloric and oxalic acids, sublimate, picric acid, and phenol, but not by formalin, hydrocyanic acid, osmic acid, or resorcin. The reaction is of great assistance in determining the distribution of myeloid tissue. W. M. Scott (Edinburgh) gives an admirable summary of the present knowledge of a difficult subject in his paper, Anaphylaxis in the Rabbit; the Mechanism of the Symptoms. Rabbits may be sensitised to foreign serum or blood corpuscles, milk, bacteria, or vegetable proteins. The dose required is much larger than where guinea-pigs are used; the sensitive state develops after ten days, lasts another ten days, and then rapidly declines. If the animal survives an anaphylactic shock it is refractory for about four days and fully sensitive again on the seventh day. Passive transference of the sensitive condition is best effected if the serum from a sensitised animal and the foreign protein are injected into a fresh animal simultaneously. There is a great variation in the degree to which individual rabbits can be sensitised; this varies with the amount of precipitin developed in their serum. The prostration and muscular paresis of the anaphylactic shock are due to a great fall of blood pressure; the portal area is intensely congested; and there is paralysis of the capillaries as well as the arterioles. The arrest of respiration is due to commencing œdema of the lungs. In the blood there are delayed coagulation and imperfect fibrin formation, a marked leucopenia; precipitin disappears completely from the serum and complement is much diminished; bacteriolytic and opsonic powers are decreased. There is some evidence of injury to the endothelium of the blood-vessels. The author attributes the anaphylactic illness to the interaction of precipitin and antigen; there is no precipitin for several days after recovery, and when it reappears the animal again becomes sensitive. The rectal temperature falls during the illness, and the gaseous exchange is diminished by about 25 per cent. Under the title Syphilis of the Lungs, with the Report of a Case, A. R. Robertson (Harvard) describes a case showing multiple gummata in the middle and lower lobes of both lungs with syphilitic aortitis and an aneurysm of the aorta. No spirochætæ could be found in either aorta or lung. J. Lorrain Smith (Manchester) continues to report observations on the Staining of Fat by Nile-blue Sulphate. Criticising Pappenheim and others who have supposed that the red colour in which Nile-blue stains neutral fat is due to metachromatism, he points out that this is incorrect. Watery solutions of Nile-blue sulphate stain fat or fatty acids red because they contain the oxazone which has arisen by oxidation of the oxazine base; they stain fatty acids blue because the colour base (oxazine) unites with the fatty acid to form a blue soap-like compound. He thinks that confusion has arisen because the oxazone and the oxazine base are both red substances and that both stain fat red because they are more soluble in fat than in the dye solution. C. McNeil (Edinburgh), in an interesting paper, discusses the Resistance of Human Red Blood Corpuscles in Health and Disease to Hæmolysis by Saponin; with a Comparison of Saponin and Hypotonic Salt Solution Hæmolysis. He investigated the hæmolytic effect of saponin on washed red cells suspended in 0·85 per cent. salt solution at 37° C.; the degree of hæmolysis was measured by using a uniform dose of red cells (50,000,000) and counting the number left undissolved at the end of the experiment. He finds that the resistance is diminished in jaundice, anæmia, and high fever; in diabetes it is increased. The resistance to hypotonic salt solution is increased in jaundice and diminished in anæmia. Experiments *in vitro* show that red cells kept for some time in a slightly hypertonic salt solution develop a much increased resistance to hæmolysis by hypotonic solutions (0·42 per cent. NaCl), their resistance to saponin remaining unchanged. The high resistance to hypotonic hæmolysis in jaundice is due to the plasma being somewhat hypertonic; the low resistance to saponin hæmolysis to the bile salts having combined with some of the lipoids of the red cell envelope. W. B. M. Martin (Glasgow) contributes an article on the Gonococcus and its Differentiation from Allied Organisms. He contends that the reaction of the medium is most important when the gonococcus has to be cultivated. To a beef broth are added 0·5 per cent. disodium phosphate ($NaHPO$), 1 per cent. peptone, and 2 per cent. agar; the reaction is adjusted to 0·6 per cent. acid to phenolphthalein (titrated hot). On to the surface of a sloped tube are run three or four drops of sterile human serum which has been heated to 57° C. for one and a half hours. On this medium gonococci grow readily. They are easily killed by cold, and it is therefore of great importance to make the cultures direct from the living bodies and to transfer to the incubator as soon as possible. Descriptions are given of the cultural appearances of gonococcus, meningococcus, and M. catarrhalis. The author finds that the ferment actions on dextrose, lævulose, maltose, and cane sugar afford important and useful differential tests. Complement deviation and bactericidal action with immune animal sera are also of service in diagnosis. The three organisms are undoubtedly distinct, though doubtful strains are sometimes met with. Abstracts of an interesting series of papers contributed as the Proceedings of the Pathological Society of Great Britain and Ireland complete a valuable number.

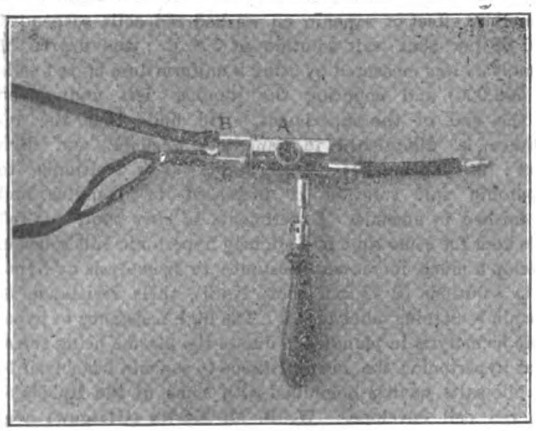
New Inventions.

NEW MEDICATED VAPOUR APPARATUS.

A NEW hot-air and hot medicated vapour apparatus has been made for me by the Sanitas Electrical Company, Limited, of New Cavendish-street, London, W., which I have found extremely useful in the treatment of chronic suppuration in the middle ear, in the antrum of Highmore, and in the frontal sinus. As will be seen from the accompanying illustration, it consists of a small cylinder A, 1¾ inches long and 1 inch diameter, fixed on a handle. On one side of this is a small mica window, through which the amount of heat produced in the coils of wire contained in the cylinder can be determined by watching the glow produced, from dull to bright red. At B is the inlet tube through which either air or medicated vapour is passed, and at C is the outlet tube. At D are the terminals connected with the wire coils, which can be attached either to a Multostat or to any accumulator working a cautery.

The following are the advantages possessed by this little instrument: It is extremely light—4 ounces with cords attached. It can be used either for hot air or for hot

medicated vapours—e.g., formalin, creasote, carbolic acid, &c. The heat is under perfect control, as is also the amount of air or vapour given. The hot air or medicated vapour can be given equally well through the external auditory meatus,



the Eustachian catheter, the frontal sinus catheter, or through a Lichtwitz's cannula into the antrum of Highmore. The price of the instrument is £2 10*s*.

J. GAY FRENCH, M.S. Lond., F.R.C.S. Eng.

Harley-street, W.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

AT the meeting of the Education Committee of the London County Council on Dec. 14th the receipt of two letters from the Board of Education was reported—one with reference to the Council's reply to the Board's criticisms of the arrangements for medical inspection in the metropolis,[1] and the other on the proposals for making a first experiment in dental treatment at the Deptford Children's Centre and the Poplar Hospital for Accidents.

The Reorganised Scheme of Medical Inspection.

With regard to the Council's reorganised scheme of medical inspection, the Board remarked that the question whether the arrangements were adequate and satisfactory was one which could not be considered merely in relation to the number of officers employed and the number of inspections which each officer might be able to carry out, and the Board was not yet in a position to express any considered opinion on the question. The Board reminded the Council that its investigations had disclosed a great lack of that organisation, direction, and control of the medical staff which was essential in dealing with the enormous area and numbers involved in the case of London schools, and particularly when the work was attempted by means of part-time school medical officers. The Board could not find in the Council's reply to its previous criticisms any clear indication of the means by which the Council was remedying, or was proposing to remedy, these defects The effectiveness of the increased staff described must depend upon the instructions under which the scheme was worked henceforward and the manner in which those instructions were observed in practice. The Board presumed, though this was not stated, that detailed instructions had been given already by the principal school medical officer to secure that the work of inspection was being regularly and continuously carried out on a definite system designed to cover the ground effectively, and that such a system was in actual operation all over London. The Board could only express the hope that when the working of the new arrangements came to be examined it would be found that the urgent needs of the metropolis in respect of medical inspection had been adequately provided for at last.

[1] THE LANCET, Nov. 5th, 1910, p. 1364.

The Experiments in Dental Treatment.

With regard to the proposals for dental treatment, the Board wrote that, while it recognised it was essential to proceed tentatively in attacking the problems with which the Council was confronted in the sphere of medical treatment, there existed an obvious and relatively pressing need that some early action should be taken to deal with those defects which seriously threatened the physical welfare of the children. The Board had been willing, therefore, to sanction certain experiments in the matter of medical treatment. It was necessary, however, that the Council should understand that the Board now felt it imperative to adopt a more critical attitude in regard to the Council's proposals, and, in particular, that the time was approaching when it would be unable to sanction the adoption of further schemes, even on an experimental basis, unless each particular scheme of treatment proposed had been (*a*) carefully thought out as regards all important details; (*b*) was so framed as to furnish full and definite information on the particular matters with which the experiment was concerned; and (*c*) had been devised so as not to hamper or embarrass the local authority in adopting any comprehensive system of treatment which might commend itself to it in the future. The Board could not too strongly impress on the Council that any satisfactory system of treatment, of necessity, must rest and be contingent upon adequate arrangements, in real working order, for regular medical inspection. As regards the proposals now in question the Board had considerable doubt whether the three conditions just laid down were satisfied even approximately. For instance, it was doubtful whether the Council, in deciding to apply the dental treatment scheme to children of 8 to 9, had selected the most appropriate age-group for conservative dental treatment. The Board noted, of course, that one of the Council's reasons for selecting this group was that arrangements were contemplated for the general medical inspection of children at this period, and that it was expected that the school doctors would be able then to select children for dental treatment. For two reasons, however, the Board doubted the wisdom of basing dental treatment upon the general medical inspection of a third age-group. In the first place, it might prove impossible for the authority to inspect this group in addition to entrants and leavers. The latter was compulsory, but the optional inspection might have to be postponed or only partially carried out. In the second place, experience showed that the findings of school doctors engaged in general inspection could not be adopted in any considerable degree as the basis for arrangements for conservative dental treatment. Reliance on this source of information involved risk of embarrassment and early confusion in the working of the scheme, and a probable failure to discover many cases which needed, and would repay, conservative treatment.

In view of these and other considerations the Board had hesitated to sanction the two proposals now before it, and the Council must not expect that the Board would be prepared to sanction for general or permanent adoption a scheme of dental treatment framed on the lines of these proposals. As they were limited in scope, of local application only, and admittedly put forward as tentative and experimental, the Board had decided to sanction the proposals, since at this juncture it was reluctant to interpose obstacles to any scheme which, however imperfect, offered a prospect of furnishing data for the Council's future guidance. This sanction would be for 12 months and was subject to facilities of inspection being afforded to the Board's medical officers and to a report by the Council upon the general working of the schemes.

The Recommendations of the Royal Commission on the Feeble-minded in Relation to Lunacy Administration in London.

Debate on this matter was postponed last week in order that opportunity might be afforded for discussion when members absent on election business could be present. But the London County Council on Dec. 13th passed the whole of the recommendations of the General Purposes Committee[1] without further consideration.

THE LANCET.

LONDON: SATURDAY, DECEMBER 17, 1910.

"Mania Contionabunda."

MEDICO-PSYCHOLOGY, responsive to what one of its continental votaries calls "the hyperæsthesia of an over-wrought civilisation," is enlarging its terminology coincidently with its subject matter, and now we have the "mania contionabunda" (the "haranguing disease") added to the "mania errabunda" (the "running-to-and-fro disease"), both of them epidemic throughout the British Isles. From Land's End to John o' Groat's, from East Lynn to Galway, the whole country is either on the tramp or on the stump, locomotion personal or vicarious lending itself to oratory shrill or subdued, diffuse or concise. Nor is there any lack of auditors, of ἀκροαταί, whether ξυνειδότες or not, till the mania in question will only cease by wearing itself out, in sheer exhaustion alike of haranguer and hearer. Meanwhile the thoughtful spectator is inclined to ask himself:—Who or what is the gainer from this babel of tongues?

If no one attempted to speak in a public way unless he had something useful and opportune to impart, the tumult and the din would subside to something like the "morne silence" of the French poet, to our manifest advantage. When the prince of orators could say of himself, as he saw his sagacious, sententious antagonist rise to reply, "See the dissector of my arguments gets up"; and when that same antagonist, on the populace applauding him, would turn round to a friend and ask, "Have I said anything particularly irrational?" we may well imagine what a DEMOSTHENES or a PHOCION would think of many a platform declaimer in the day now passing! For, with the fewest possible exceptions, we have only in his declamation what the Scotch professor remarked in a loquacious student, "a determination of words to the mouth," a "relaxation of the mental sphincter," a paralysis of that inhibition which sane and circumspect thinking imposes on the tendency to utterance. One of the many proofs of DICKENS'S power of psychological delineation is his character of FLORA in "Little Dorrit," the amiable, expansive lady whose talk is a palmary specimen of the inhibitory paresis referred to, talk which runs on as continuous as it is inane, sentence suggesting sentence by the faintest links of association, often merely verbal in their affinity. The diction, too, of the platform declaimer is typical of the thought it conveys—diction drawn from what Mr. GEORGE WYNDHAM, in his contrast between NORTH'S "Plutarch" and the version of the brothers LANGHORNE, has called the "charnel-house of decayed metaphor"—diction deliciously quizzed by D'ISRAELI in "Tancred" when, weary of "leaving no stone unturned" before "embarking on the next feature on which this question hinges," he remarks that John Bull is sorely in want of a new set of similes. That greatest parliamentarian of the Victorian era, WILLIAM EWART GLADSTONE, though himself often enough incurring D'ISRAELI'S satire, conveyed a rebuke to much of the "eloquence" of his day, when in his "Homer" he defined the requisites of the public speaker. He must never be over the heads of his hearers; he must have the power of making them feel and think with him; he must have the "obstetric art" (the τέχνη μαιευτική) of SOCRATES, evoking from them sentiments, sympathies, conclusions latent in their minds, but only awaiting the magic touch of his "delivery" to start into life; or in GLADSTONE'S own felicitous words, "What the orator receives from his audience in mist, he gives back to it in rain." Such was the oratory of a PERICLES in the palmy days of Athens; of a CHATHAM in the British Senate; and of a LINCOLN in the great Republic of the West; not the incontinent cerebration which passes for oratory on the modern platform, where, but for the reporter amending him, the orator would turn out as ungrammatical, not to say incoherent in phrase, as but for the same press he would often be poor in ideas.

In a memorable passage published 60 years ago CARLYLE sounds a characteristic note of warning: "Be not a Public Orator, thou brave young British man, thou that art now growing to be something; not a Stump Orator, if thou canst help it. Appeal not to the vulgar, with its long ears and its seats in the Cabinet; hate the profane vulgar and bid it begone! Appeal by silent work, by silent suffering, if there be no work, to the gods who have nobler than seats in the Cabinet for thee!" A warning this as relevant in the day now passing as it was in 1850—a warning intensified by the deterioration of parliamentarianism abroad with its free fights in the Chamber, its scuffles in the lobbies, and its duels in the open—a warning not without significance nearer home, where, particularly north of the Tweed, the pulpit itself is degraded by becoming "a coign of vantage" for partisan pleading, till protests against the practice are to be read *passim* in the public prints—nay, are to be heard from scandalised worshippers in the house of prayer itself! The haranguing disease is on us.

Diet in Disease.

IT is related of GRAVES, in a well-known anecdote, that he said, "If you are at a loss for an epitaph to be placed on my tomb, here is one for you, 'He fed fevers.'" This was some 60 years ago. The two generations of physicians that have practised since his day have, with few exceptions, followed his example. With the very large amount of experimental work that has been done in recent years, more particularly in Germany and America, in the study of the chemical processes of nutrition, we are now much better able than our predecessors were to supply the needs of the patient, without unduly straining his powers of digestion and assimilation. The two perfect foods with which Nature has herself provided us still form, as no doubt will always be the case,

the staple invalid dietary; but inasmuch as milk and eggs are adapted for the needs of the healthy organism, it is not flouting Nature to modify their composition when using them for the sick. Thus the dilution of milk with water, the addition to it of an alkali, its modification so as to form whey, are obvious modes of adapting it to the impaired digestive powers of the fever patient. Such a patient is unable to deal with solid food of any description; and much ingenuity has been shown in the endeavour to extract from the meat that forms a part of the ordinary diet in health so much of the nutritive protein material as may be obtained in a fluid and assimilable form. Beef-tea has, however, long been considered to be little more than an agreeable stimulant, and, however carefully prepared, to have small direct nutritive value, though it may be a means of assisting the assimilation of nutrient materials. We know, at any rate, that it does stimulate, it is readily absorbed, and the contained salines (potassium chloride and sulphate) are of some use. Gelatin, in the old-fashioned form of calves'-foot jelly, at one time considered highly nutritive, has since been relegated to an inferior position as a mere placebo, but it has now been shown to be, though not actually a tissue-former, a protein-sparer of considerable value; it is a means of saving the albuminous waste from the tissues, and "from this point of view cannot be too strongly recommended." We quote here from Dr. CHALMERS WATSON, who, in a work just published,[1] has brought together in compendious form the results of recent research and clinical observation.

Under the conditions that obtain in a normal state of health the relative worth of the various food substances may be readily ascertained by a computation of their calorie values, as to which there is now a general agreement amongst analysts and physiologists; and in this way standard dietaries have been framed for the occupants of public institutions, and for large bodies of persons, such as soldiers and sailors, inmates of workhouses, prisons, and so on. But for the sick the diet has to be adjusted in each instance from a knowledge of the digestive and assimilative powers of the individual patient; little clinical importance can be attached to the calorie value of the food; it is the personal factor that has to be considered in each case. Moreover, in practice it is not unusual to find *a priori* physiological considerations to some extent falsified. Dr. WATSON mentions the group of meat infusions, juices, and extracts as being largely administered, and their usefulness universally admitted. We are aware that many authorities deny that these substances have any physiological value at all worth mentioning; and judging from their chemical composition alone this would appear to be the case, but they continue to be employed, both in hospitals and in private practice; and we believe that the medical profession generally have a high opinion of their value in cases of fever, exhaustion, and acute illness generally. The impressions derived from clinical experience have not, at any rate as yet, given way before the hard facts of laboratory experiment.

[1] Food and Feeding in Health and Disease, a Manual of Practical Dietetics. By Chalmers Watson, M.D., F.R.C.P. Edin. London and Edinburgh: Oliver and Boyd. Pp. 638. Price 10s. 6d. net.

On the other hand, in recent years immense benefit in treatment has resulted from the increase in knowledge regarding the bio-chemical processes that are carried on in the alimentary tract. Bacterial activity in the intestine may be greatly modified by alterations in the diet: a restriction in the protein ingested diminishes putrefactive decomposition, and a reduction in the carbohydrates lessens the development of injurious acids and gases due to fermentation. The contents of the intestine cannot be made aseptic, but dietetic regulation can materially reduce the formation of toxic products. Much attention is nowadays paid to oral sepsis, often due to accumulation of decomposing particles of food between the teeth which eventually leads to a septic condition of the gums and mouth generally. Whether occurring in the mouth or in the intestine sepsis may lead to impairment of health; it arises largely from causes connected with the diet, and by means of dietetic regulation may in most cases be overcome. One particular affection, arterio-sclerosis, though not at first sight connected with conditions of alimentation, being frequently dependent on prolonged high blood pressure, is considered in some cases to result from a poison formed in the intestinal tract; this may arise either from abnormal digestion of proteins (especially of animal origin in constipated subjects); from abnormal fermentation of carbohydrates, or from an excess of nutrient material beyond what can be dealt with by the organism—that is, over-eating. Restriction in animal protein food is indicated, and also careful regulation of the bowels. In functional heart derangements, so often due to indigestion, dietetic treatment is obviously of great importance; but in chronic organic disease of the heart also—for which HAYLE WALSHE, a paramount authority in his time, stated that no constantly applicable rules could be laid down, except that moderation is important, especially in fluids—Dr. WATSON now suggests fairly precise directions, carbohydrate food being especially restricted. It is enough merely to mention gout, diabetes, and asthma as instances of pathological conditions largely dependent on variations from the normal working of the alimentary system, and capable, therefore, of being influenced by dietetic regulation. We have heard much of the advantages of a purin-free dietary: they are undoubted. Dr. WATSON ascribes them rather to the simplicity of the system, which enables it to be carried out more rigidly, and therefore more successfully, than other dietaries framed on conventional lines, than to any specific action associated with the absence of these substances. But in this as in most other advances in dietetic treatment the main feature in the practice of the present day is the application to therapeutics of the large additions that have been made in recent years to our knowledge of the bio-chemical processes carried out in the small and large intestines. Much has been learned, but with increase of knowledge comes fuller appreciation of the complexity of the metabolism at work. What formerly appeared simple, on further investigation is found to be quite the reverse. But, step by step, progress is being made, and, as we have tried to indicate, the therapeutist is keeping in close touch with the physiologist.

Reform at the University of Oxford in Relation to Medicine.

ON April 28th, 1909, the Oxford University Press issued a Memorandum drawn up by Lord CURZON OF KEDLESTON, Chancellor of the University, in which he discussed various proposals and suggestions for reforms dealing mainly with the constitution of the University of Oxford and with certain financial questions. The Hebdomadal Council thereupon held a series of meetings, and eventually passed a number of resolutions pledging itself to a definite scheme of policy upon almost every debated issue of University reform. Committees were appointed to take evidence and to consult authorities with a view of framing plans for the carrying out of the aforesaid resolutions. The reports of these committees were debated line by line in full Council, and the result of this deliberation was the comprehensive report of the Hebdomadal Council which was issued some months ago. No doubt statutes based upon this report, the debate on some of which has already begun, will continue to be submitted during the next few terms to Congregation and Convocation.

On the appearance of Lord CURZON'S Memorandum we commented upon features of it which appeared to us to have a special bearing upon the interests of the medical profession.[1] We pointed out that if, in accordance with the views of the more ardent reformers, all members of Convocation other than those in residence were for certain purposes to be struck off the roll of voters, such disfranchisement would have a most disastrous effect upon the future of the Oxford Medical School, because the majority of Oxford men who seek a medical degree study their medicine outside of Oxford. If such disfranchisement, then, were carried into effect, all the 190 or so medical members of Convocation who are non-resident, and who are either engaged in teaching or have the interests of medical education at heart, might be deprived of any voice in the management of the medical school. We further pointed out that Lord CURZON'S eminently judicial presentment of the various plans for reform did not even take into consideration any reform of this kind, and we merely mentioned it as being the view of one school of reformers. We are glad to see, then, that by the report of the Hebdomadal Council it is proposed to leave the constitution of Convocation practically untouched, so that it will be still the supreme legislative authority of the University. It is suggested, however, that its action should be restricted in certain cases, so that where Congregation has voted unanimously on any statute in its final form, such shall become law without being referred to Convocation, and also that any statute which shall have been passed in its final stage by a two-thirds majority of Congregation shall take effect, unless Convocation rejects it by a two-thirds majority of those voting. The voting power of the medical members of Convocation outside of Oxford would therefore remain practically unaltered. We understand that even this alteration of the powers of Convocation would require an Act of Parliament, and therefore assume that this part of the scheme will not be proceeded with. That portion of the report which is of most direct interest to the medical profession is embodied in a statute, where it appears as Sectio VIII., "Of the Faculty of Medicine and of the Board of that Faculty." By this section it is proposed that the Faculty of Medicine should receive special treatment, and, unlike any other faculty, should possess a General Medical Electorate consisting of all Oxford graduates in medicine who are members of Convocation. The Board of the Faculty is to include *ex officio* members—namely, the various professors and readers in the faculty and the representative of the University on the General Medical Council; nominated members, three in number, who are to be chosen by the Board of the Faculty of Natural Science as representing physics and chemistry, zoology and botany, and organic chemistry in relation to physiology and medicine; elected members, six in number—i.e., three being members of, and elected by, the faculty, and three being members of, and elected by, the General Electorate aforesaid. At least two of the latter shall be engaged in teaching one or more of clinical subjects of the faculty. There may be in addition not more than four co-opted members, of whom at least half shall be engaged in teaching clinical subjects. The three members of the Board elected by the General Electorate shall be elected annually, and nominations must be made by not less than six members of that Electorate. Among other powers, the Board of the faculty is to have power to institute a University Medical Students Register. This scheme, to which the deliberations of committees of the Hebdomadal Council and of the Council itself have given rise, may, of course, undergo alterations at the hands of Congregation and Convocation, but as it stands we welcome it as an honest and painstaking attempt to bring the teaching of medicine at, and the Medical School of, the University into touch with those medical graduates whose lot in life it is to teach and to practise medicine without the walls of their University.

The provision of the General Medical Electorate is, in our opinion, a valuable one, and we earnestly hope that this part of the scheme may pass without serious amendment. It is a scheme which possesses, or should possess, the rare excellence of reconciling the two diverse parties—viz., the ardent reformers and those who wish to maintain the mediæval methods of government and constitution of the University. The former should welcome it, inasmuch as it provides that those engaged in the teaching and practice of the subject of a faculty should be those who have the right to vote upon, and to take part in, matters affecting that faculty. To the latter it should be no less welcome in that it is a return to the mediæval idea that all the members of the "universitas," or guild of teachers, should be consulted before a new candidate was admitted to their number. In the beginning the University of Oxford was simply a guild of Masters of Arts and the votes of all the Masters had to be taken before a new Master was admitted. And when other faculties came into existence the consent of the Masters was still necessary, and in theory is still asked at Congregation by that curious, but—if rightly understood—dignified, survival the Proctors' walk. The calling into the counsels of the Faculty of Medicine all the graduates in that Faculty is therefore not so much an innovation as an expansion of one

[1] THE LANCET, May 29th, 1909.

of the oldest of University customs, for although the Medical Electorate as such will not be consulted as to admission of candidates to a degree, yet its members will have a voice in their teaching and training for a degree in medicine.

Annotations.

"Ne quid nimis."

THE GENERAL ELECTION AND PUBLIC HEALTH.

THE occurrence of general elections in relatively rapid sequence is not in the interests of public health. At no time, indeed, can it be said that a general election is conducive to physical well-being, since it is a time of some tension—it involves certain work generally carried out under trying circumstances which are not calculated to influence the health favourably. The general election is a time, for example, when great meetings are held; vast concourses of people are brought together in a confined space in which, in most instances, the call for an unlimited supply of pure air is not met; diseases chiefly of the respiratory order are consequently easily communicated and spread. "I caught a cold and sore-throat at the political meeting last week," is an observation commonly overheard just now. Again, there is the street meeting, which, although the air may be fresh, is held sometimes under conditions of a most exacting kind on the health. Crowds of eager voters will be found huddled together listening to political arguments in pouring rain or in the blast of a biting wind, and is it matter for wonder that a good percentage of the audience gathered together under such circumstances contracts respiratory trouble, neuralgia, and rheumatism? Then either the exuberance or depression of the spirits dependent upon the success or failure of the party to which they belong leads many individuals to alcohol, the political clubs and the village public-houses are crowded, drinks are indulged in to console on the one hand or on the other to celebrate success, and the cause of health is badly served. The rowdyism of the modern election is of a very mild type compared with that of the days of George II., vividly illustrated by Hogarth in his "Election Series," though discreditable events have been freely reported during the past ten days; but physical violence appears to have given way to a policy of wilfully misrepresenting facts. It has not been uncommon to see two newspaper bills side by side with diametrically opposed statements set out in big type upon them. We believe veritably that rowdyism was preferable to this crude mendacity. A broken head may be a more definite medical lesion than an affronted intelligence, but the irritation that has been caused by partisan journalism during the last fortnight has told on the nerves of the nation much as an epidemic might have done.

THE MEDICAL DIRECTORY, 1911.

THE annual Medical Directory[1] for 1911 has been issued by Messrs. J. and A. Churchill and fully sustains the reputation that the previous 66 issues have achieved for it. Reference to the table summarising the geographical distribution of the profession shows that the total increase of registered practitioners for the past year is 173. London shows a decrease of 12 and the services of two, an increase in the other sections being shown as follows: Provinces, 153; Wales, 22; Scotland, 11; Ireland, 1; while those resident abroad number exactly the same as in the previous year. The total number of registered practitioners is 40,642, distributed as follows: London, 6415; Provinces, 17,721; Wales, 1336; Scotland, 3958; Ireland, 2724; abroad, 5188; and the services, 3300. To the customary useful information concerning sanatoriums, institutions, laws affecting the profession, climatic resorts, &c., there have been added a new list of coroners, which occupies over four pages; a summary of the law as to cremations "in view of the steady increase of the number of cremations"; and information concerning the motor-car and petrol rebates allowed by the Finance Act to medical practitioners, details of which have already appeared in THE LANCET. The list of British health resorts, compiled by Mr. Norman Hay Forbes, F.R.C.S. Edin., which formed a new feature in last year's Directory, has been thoroughly revised, and its scope has been enlarged so as to include the principal continental spas and climatic health resorts, the information concerning which, so far as we have been able to test it, appears to be accurate and sufficiently complete. The increase in size of the volume to 2168 pages has not affected the price, which remains at 14*s*.

THE CARBOLIC COEFFICIENT OF ESSENTIAL OILS.

SINCE the value of essential oils in their application, at all events, to medicine, depends probably upon their antiseptic power, the determination of this power is important. Following THE LANCET method which was set out in the report of THE LANCET Commission on Disinfectants, with slight modifications, Mr. W. Harrison Martindale has recently published an interesting series of figures which purport to give the phenol coefficient of the chief essential oils, in an article published in the November number of the *Perfumery and Essential Oil Record*. The results are summarised in the following table, the carbolic acid coefficients there recorded being the mean of the two results obtained with 2 minutes' and 30 minutes' contact respectively:—

Essential oil dilution.	Carbolic acid coefficient.
Origanum oil (aqueous)	25·76
Thymol (saponaceous solution)	25·29
Carvacrol	21·32
Thymol (in aqueous solution)	19·41
Thyme oil (in soap)	14·85
Thyme oil (aqueous)	13·38
Geraniol (in soap)	12·29
Cinnamon leaf oil (in soap)	9·66
Oil of cinnamon cortex (in soap) (52 per cent. aldehyde)	8·91
Oil of cloves (in soap)	8·88
Cinnamic aldehyde (in soap)	8·02
Citronellol (in soap)	8·11
Oil of cinnamon (82 per cent. aldehyde) (in soap)	7·92
Rosemary oil	5·94
Otto of rose (in soap)	5·94
Cassia oil (in soap)	5·94
Wintergreen oil (in soap)	4·64
Eucalypt. amygd. (in soap)	4·35
Lavender oil (English) (in soap)	4·94
Lemon oil (in soap)	3·94
Almond oil (in soap)	3·76
Eucalyptol (in soap)	3·76
Eucalypt. glob. oil	3·55
Light oil of tar (rectified)	2·17
Santal oil	1·67
Birch tar oil	1·67

It will be noted that in the majority of instances the oils were tested in saponaceous solution—that is to say, a limpid solution which throws out on dilution the oil globules in a fine state of subdivision. There is no information given as to the relative physical condition of the emulsions tested,

and it is apparently assumed that the state of subdivision in all cases was the same. If that was not the case, the relative values of the oils in regard to carbolic coefficiency may not necessarily be dependent upon the essential constituent, for undoubtedly a greater inhibitory action on organisms is shown by a perfectly uniform emulsion, in which the separated particles are exceedingly fine, than by an emulsion which exhibits irregularities or suspended particles varying in dimensions. It is interesting to note, however, that origanum oil, which heads the list, was found to give much the same germicidal effect whether used in aqueous or saponaceous solution. Generally speaking, however, the saponaceous solutions showed to advantage when compared with aqueous solutions—e.g., thymol in the above table. The results are extremely interesting and go to show that we are not necessarily dependent upon disagreeably smelling phenol compounds as the basis of strong germicidal preparations.

A COLD NOVEMBER.

NOVEMBER was in many respects an unusual month. It was in no wise remarkable for its fog, although London and some other localities were not quite exempt. In the matter of fogs, however, November has obtained an evil name somewhat undeservedly, for it is a fact fully proved by statistics that it is not so foggy, as a general rule, as either December or January. The first taste of London winter fogs generally occurs some time during November, and perhaps the first visitation makes more impression on the public memory than the later ones, however more unpleasant they may be. The chief feature of last month was its low temperature: it was not that there was a continued frost such as that which made skating possible during November a few years ago, but the persistent manner in which the thermometer remained several degrees below the average during the daytime, and the frequency of frosts —often of relatively slight intensity—at night. During a considerable portion of the month the temperature ranged between 5° and 7° below that ordinarily experienced at the time of year, and was generally at least 4° below it. In London the mean afternoon warmth was about 4° less than usual, and that of the nights 5½° less, while in some other parts of the country the divergence from the normal was greater. The coldest nights showed minimum temperatures of 25° (on the 18th, 22nd, and 23rd) by the screened thermometer in St. James's Park, and frost of lesser severity was recorded on as many as 15 other nights. The month was also very wet, and this is a quite rare combination for the time of year. In the summer a wet period is almost always a cool one, but the reverse is generally the case after October. A cool summer month has, with a rare exception, a relatively poor supply of sunshine, and a wet November is usually very gloomy. In the present case, however, the duration of sunshine was almost everywhere in excess of the normal. Even Westminster, which scarcely saw the sun for more than a minute after the 21st, recorded 36 hours, which is equal to an excess of 20 minutes per day, and at places on the coast the figure was very high for the season. In many parts of the kingdom the rainfall was abnormally heavy. In the western and south-western districts hardly a day passed without a measurable quantity finding its way into the gauge, and some northern districts were little better, while the extreme south-east, although not so interruptedly rainy, has a very heavy total. One of the wettest spots was, indeed, the south coast of Kent, where the aggregate amounted to nearly 7 inches, or more than that on the west coast of Ireland and in the rainy Hebrides. But the most hopelessly wet region was the Channel Islands. At Jersey there were only three days without rain, and the total fall, 10·85 inches, is probably without a record for November, and it may be for any other month. In London the falls were not so heavy, and 19 days with rain yielded no more than 2·87 inches. The wet conditions were not experienced in this country only. France as a whole was almost as rainy, and in some departments even more so, while the resulting inundation was certainly far more serious. In the well-known south-western corner of France in which Biarritz is situated there were about as many rainy days as in London, and the actual fall was not far short of twice as great. The Riviera was a fortunate exception, the greater part of the month being fine and mild or warm, and the rain coming down in one or two semi-tropical downpours. A great deal of rain fell in Italy, as is generally the rule in the late autumn, but the weather in its main aspects was not unfavourable, the sun shining brightly for some hours on a great proportion of the days, and the thermometer seldom failing to reach the genial figure of 60° in the shade except in the inland northern districts. In Sicily and Malta shade temperatures of 70° or higher were of almost daily occurrence, and the weather of the month was composed of the agreeable mixture of occasional rain divided by many days of clear or nearly cloudless skies. Algeria was as warm as London during an average July, the sky nearly always clear, and rain very infrequent.

BRACHIAL NEURITIS FROM PRESSURE OF THE FIRST RIB.

IN recent years attention has been called to the fact that obscure cases of nervous symptoms in the arm may be due to the presence of a cervical rib which presses on the brachial plexus. In the *Australian Medical Journal* for October Dr. Thomas Murphy has reported a case of this class in which the symptoms were due, not to a supernumerary rib, but to the normal first rib. No case of this kind appears to have been previously recorded. A single woman, aged 28 years, came under observation in June, 1910, complaining of pain, numbness, coldness, tenderness, and weakness in the left shoulder and arm and swelling and dusky-blue discolouration of the hand. The symptoms were worse after exerting the arms, as in tennis or typewriting. They were severe and always present in winter, but present only after exertion in summer. The first attack occurred in 1902, when the pain was severe, and she was treated for neuralgia. In the winters of 1903 and 1904 the symptoms were much the same. In 1905 the pain was more severe and the hand became swollen and dusky-blue. In 1906, in addition, she complained of a feeling of fatigue in the left shoulder and across the left side of the chest, and a "cramped feeling" in the throat, and at times could not swallow. In 1908 the arm and forearm were markedly wasted. In 1909 the symptoms were less severe. On examination the arm, forearm, and hand were tender throughout. The hand and forearm were cold. The wrist and hand were swollen and dusky-blue, suggesting severe chilblains. There was no œdema, such as would point to pressure on venous trunks. There was some loss of power in the arm and hand; the latter could not be closed. Some wasting of the forearm and impairment of sensation in the hand were found. The signs and symptoms pointed to neuritis. On pressure over the brachial plexus in the neck, behind the sterno-mastoid, a tender point of resistance was found, and shooting pain in the arm was produced. The possibility of a cervical rib suggested itself, but a skiagram failed to show one. However, in view of the resistance and tenderness in the neck, operation was advised. While the patient was being anæsthetised pressure on the brachial plexus caused twitching of the arm. An L-shaped incision was made behind the posterior border of the sterno-mastoid.

On incising the deep fascia the brachial plexus was exposed lying on the glistening insertion of the scalenus medius. The plexus was drawn inwards and the point of resistance, noticed before the operation, was found to consist of the insertion of the scalenus into the rib. This insertio with the bone gave the sensation of a swelling, over which the plexus passed. The muscle was divided near its insertion and the bone exposed. There was no swelling on the rib, which was cut through with forceps at the insertion of the muscle and then removed piecemeal, the soft parts being protected with a blunt spatula. A smooth bed was left for the plexus when replaced. The deep fascia was sutured with catgut and the wound closed. The operation was completed at mid-day, and at 5 P.M. the patient drew attention to the fact that her hand was white and normal in colour, though it had been dusky-blue for three months. After a week she could close her hand perfectly. The symptoms disappeared and the pain did not return in spite of exertion such as typewriting in extremely cold weather, and the arm and hand regained power. A skiagram taken after the operation verified the fact that the first rib and not a supernumerary rib had been removed. The symptoms produced on exertion appeared to have been due to the rolling motion which the scalenus medius on contracting would cause in the already stretched plexus at the point where the nerve trunks passed over the prominence made by the insertion of the muscle into the bone. Dr. Murphy saw a case of operation for suspected cervical rib in London last year, in which no such rib was found. He suggests that the case was probably similar to his. An apparently normal first rib, it seems, may cause severe nerve symptoms, a fact which throws light on some hitherto obscure cases.

A CLEAN MILK CAMPAIGN.

IN order to consolidate public opinion in readiness for the time when general legislation will be introduced for the purification of our milk, a joint committee of the National League for Physical Education and Improvement and the National Health Society has prepared and issued three leaflets, addressed to farmers and producers, to distributers and retailers, and to housewives and all consumers of milk respectively. They are brief, clear, and concise, and having been prepared by a committee, including representatives of the medical, veterinary, and legal professions, of the Local Government Board, local authorities, and farmers and dairymen, the directions and advice given may be taken to be both soundly scientific and practical. Much attention has lately been directed to the purification of the milk-supply, and local authorities have obtained and are using powers to trace to their source certain forms of milk contamination, notably tuberculosis. In addition to these special powers all local authorities have the power and duty of compelling cleanliness in dairies, cowsheds, and milkshops, ensuring as far as possible freedom from contamination until the milk is in the hands of the consumer. These measures often fail in their effect through lack of public opinion to support them, and they are in many instances rendered futile by the ignorance and carelessness of consumers. It is important to success that vendors should realise that the reputation for clean milk is essential to their own interests, and such admirable rules as the suspension from duty for considerable periods without loss of wages of dairymen in whose homes infectious diseases have arisen should lead the public to patronise those dairy companies which make and keep them. Such a rule is itself a guarantee that the other precautions necessary for obtaining uncontaminated milk are carried out in these establishments. When Bills have been passed, and supervision of production and control of distribution have been obtained, the problem will still remain of educating the consumer, and it is to such national societies as these, which have prepared and are circulating advice and information among the people, that the lot will fall of overcoming the last line of resistance to a purer milk-supply.

REFLEX ANURIA.

THE subject of reflex anuria is difficult and in need of further elucidation. In the *Medical Review* for December is related an instructive case, taken from the Archives of the Middlesex Hospital. A stout multipara, aged 49 years, was admitted under the care of Sir A. Pearce Gould on March 1st, 1910. Six years previously she was seized with severe pain in the left lumbar region which lasted several hours. Similar attacks followed, the last on Feb. 18th. Attacks of pain also occurred in the right loin but were neither so frequent nor severe as on the left side. The pain was accompanied by vomiting and constipation and inability to pass urine. Before the attacks she noticed that the urine was dark, and she thought she had seen streaks of blood in it. In consequence of her stoutness abdominal examination was difficult. Both lumbar regions were tender, and there was dulness in the left flank, which did not shift with her position. The urine varied in specific gravity from 1005 to 1012, was slightly alkaline, and always contained albumin and sometimes a little pus and blood. Skiagraphy showed three shadows in the left kidney but nothing in the right. As obesity rendered her an unfavourable subject for operation, and the symptoms were somewhat ambiguous, she was kept under observation. She complained of pain across the lower abdomen, and only with difficulty could it be found that she had more pain on the left than on the right side, and that there was more tenderness in the left flank than in the right. On March 14th the left kidney was exposed from the loin and found enlarged and mottled. It was incised and three irregular oxalate of lime calculi were extracted from dilated pus-containing calyces. The section of the kidney was grey and yellow, and the organ was obviously much diseased. A drainage-tube was inserted. After the operation the urine contained more pus, but was excreted in considerable quantity. She did well until April 9th, when she was quiet and almost apathetic. The total urine passed per urethram, which had averaged 50 ounces, fell on the 8th to 15 ounces; on the 9th and 10th not a drop was excreted; on the 11th only half an ounce; and on the 12th 1 ounce. From the wound only a little pus was escaping. The urine was very turbid and contained only 0·1 per cent. of urea. It was concluded that there was anuria from blocking of the right ureter by a calculus which had probably been the cause of the pain on that side and was too small to be shown in a skiagram in so stout a woman. Operation on the right kidney was urged, but declined. Hypodermic injections of pilocarpine, diuretin, and saline enemata were repeatedly given and she sweated profusely. On the 12th she was very weak, but there were no definite uræmic symptoms and permission for an operation was given. On exposing the right kidney from the loin a small stone was found impacted in the neck of the ureter, and a bougie was passed down into the bladder to make sure that there was no other calculus. Urine flowed from the ureteral wound as soon as the stone was extracted. A drainage-tube was inserted. She rapidly improved and on the 15th passed 20 ounces of urine per urethram, and by the 19th the quantity had increased to 45 ounces. In May she had completely recovered except for a sinus in the left loin. Sir A. Pearce Gould explains the symptoms as follows. When the small calculus in the right kidney passed into the narrow neck of the ureter it not only prevented the passage of urine but arrested the secretion of the opposite kidney by reflex

stimulation of the vaso-constrictor nerves and inhibition of the secretory nerves. After its removal, while the urine from the right kidney was escaping through the drainage-tube, urine quickly appeared in the bladder, mostly, if not wholly, from the left kidney. Further evidence of the influence of the impacted stone upon the secretion of the opposite kidney is the fact that urea in the urine passed after the operation rose to over 1 per cent. in contrast to the 0·1 per cent. before. This reflex arrest of secretion in a diseased kidney by impaction of a calculus in the opposite ureter is analogous to the anuria occasionally caused by a urethral operation when the kidneys are diseased. It is an interesting example of the fact that reflex effects depend partly on the condition of the part to which the efferent impulse is sent. Indeed, it is believed that calculous occlusion of one ureter never causes fatal anuria if the opposite kidney and ureter are healthy.

THE OVER-HEATING OF HOUSES.

THE excessive humidity which has characterised the weather during the year now drawing to a close, and more particularly throughout the month of November, has re-directed attention to the much-debated question as to the methods of heating best adapted in this country for comfort as well as health. We are often accused of being old-fashioned, especially by Americans, and nothing surprises our professional brethren from the other side more, used as they are to hot air or steam heat even in private houses, than the open fire-places still found in many of our hospitals. That their more "up-to-date" methods are not free from defects is, however, being gradually forced upon the American nation, and it is not without significance, therefore, to find that the *Boston Medical and Surgical Journal* of Nov. 17th has been inveighing against them in no uncertain terms. According to this authority, the average temperature of the American furnace-heated home is 76° F., as contrasted with 60° F. in England. But it is in the comparative humidity that the most striking difference lies. We are not afraid of moist air; it is responsible for the clear complexions, and absence of wrinkles, characteristic of us, although, it is true, it renders us more liable to rheumatoid affections unless carefully regulated. The average humidity in the United States and Canada is very much less than in this country, but the Canadian and American take care to reduce the proportion still more by their customary methods of heating. Indeed, to such a degree is this carried out that the humidity often falls as low as 16, according to the article from which we are quoting, which is about half the humidity of the Desert of the Sahara, the mean humidity of which is stated to be 30. The consequences of this extraordinary dryness in the atmosphere of the home are not without manifestation. The surface moisture of the body is eagerly absorbed by the parched air, the mucous membranes of the throat, nose, and pharynx become dry, congested, and liable to any prevalent infection, and the heat-regulating mechanism of the body fails to react when its owner has to go out into the cold. As a result the "great American cold" of Elizabeth Robins, the "fall cold" of the lay papers, and the "chronic American naso-pharyngeal catarrh" of the medical press has the nation in its grip every succeeding winter, and the "one-night-cough-cure" quacks, the numerous, much advertised "anti-catarrh" remedies, and the makers of "cuspidors" reap a plentiful harvest, while extra labour is also thrown upon the medical profession. The *Boston Medical and Surgical Journal* roundly states that the super-heated American house is "a medical barbarism and an anachronism in this age of enlightened progress." Many English medical men have had the same view when sojourning across the Atlantic; but, on the other hand, it cannot be denied that we, here, err in the opposite direction, for draughty corridors, ice-cold bedrooms, and chilly living-rooms claim their quota of victims each succeeding winter. The happy medium in this country would seem to be an employment of the two methods, utilising the ventilating powers of the open fire as well as the equable heat given out by the steam radiator, but only a few of our more modern dwellings as yet offer such a combination.

THE ULTIMATE RESULTS OF GASTRO-ENTEROSTOMY.

GASTRO-ENTEROSTOMY has for some years enjoyed a high reputation in the treatment of many disorders of the stomach, both obvious and obscure, and although its reputation is not quite what it was, yet it is still employed frequently by many surgeons. This is not surprising, for in most cases the temporary results, at least, are very good, while the patient is in bed in hospital and is judiciously dieted. The permanent results, too, in some cases are truly wonderful. Patients who have been in a state of chronic invalidism for 10 or 20 years have, as it were, regained their youth and the health and freedom from gastric disturbance so characteristic of the young. Many physicians, however, have seen no small number of patients who have suffered from a return of the symptoms after having undergone the operation of gastro-enterostomy, and it occurred to Dr. Otto May, when he was medical registrar to the Middlesex Hospital, that it would be of interest and value to trace the after-history of patients on whom the operation of gastro-enterostomy had been performed at that hospital. He excluded all malignant cases, for obviously they could afford no information of value. He selected the three years 1906, 1907, and 1908, so that sufficient time might have elapsed between the performance of the operation and the date of investigation. Of the 90 patients upon whom the operation had been performed he was able to obtain information as to the results in 65. In order to arrange the results statistically he divided the cases into four groups. In the first are those in whom the result is entirely satisfactory; they can do their usual work without discomfort, provided they use reasonable care in their dietary. In the second class he puts those where occasional attacks of pain or vomiting occur in spite of ordinary care, but where considerable improvement has resulted. In the third class are those in whom slight improvement has occurred, but the gastric conditions are sufficiently troublesome to interfere seriously with the capacity for work. In the last class Dr. May puts those cases in whom no definite improvement can be found. As to the results, rather less than half (46 per cent.) were "cured," while another 20 per cent. were greatly relieved, but in 23 per cent. of the whole the operation had to be described as a total failure, and only slight benefit had occurred in the remaining 11 per cent. The cases which gave almost uniformly good results belonged to two classes: (1) dilatation of the stomach caused by pyloric obstruction; and (2) duodenal ulcer. Apparently, also, some cases of gastric ulcer without pyloric obstruction received much benefit. Dr. May comes to the conclusion that gastro-enterostomy is contra-indicated in that fairly large class of women who suffer from pain and flatulence, but in whom no definite evidence of organic trouble can be found. He suggests that the fundamental indication for the operation is marked delay in the emptying of the stomach after a simple test meal, and he thinks that the skiagraphic method is the most trustworthy one for this determination. We might also mention that although the numbers of men and women patients in the series were almost equal, 34 of the patients being men and 31 women, yet of the men 22

completely recovered but only 8 of the women. It is worthy of note that in five of the cases of women the stomach and duodenum appeared normal at operation, and in these the results were almost uniformly unfavourable. We think that Dr. May has done a very useful piece of work much needed at the present time.

PLURALISM AND THE LEEDS GENERAL INFIRMARY.

ON Nov. 18th the weekly board of the General Infirmary at Leeds passed the following new rule, which was considered and confirmed at a meeting of subscribers held on Dec. 8th:—

That from and after Jan. 1st, 1916, members of the full honorary staff shall not hold any other honorary hospital appointment than their appointment at the Infirmary.

That from and after Jan. 1st, 1916, members of the assistant honorary staff shall not hold more than one honorary hospital or dispensary appointment in addition to their appointment at the Infirmary, and that such additional appointment must not involve the charge of beds.

Provided that this shall not be held to prevent members of the staff from holding consulting appointments at other hospitals, appointments at the University of Leeds, or appointments to offices in the Territorial Medical Force, or (so long as they are not elected to a different position from that now held by them) from retaining appointments now held by them.

The question of pluralism in hospital appointments is one which promises in future to engage the attention of the medical profession more closely than hitherto. It is a question upon which opposing views are held, not only because individual interests clash, but also on the general principles involved. Whether it is better or worse for particular institutions and for medical science that the members of the medical and surgical staffs should also hold similar appointments elsewhere, or that their services and skill, gratuitously given, should be monopolised by the institutions to which they first become attached, are questions to which a well-considered answer may be required. The sweeping away of old institutions is liable in most cases to lead to individual hardship, but that the new rule in Leeds will not operate harshly is indicated by the provision made in the last paragraph to exclude present members of the staff from its scope so long as they continue to hold their present posts at the infirmary, and also by the date, five years hence, at which the rule is to become operative.

FIGHTING DIPHTHERIA AT CHICAGO.

THE Department of Health of Chicago has issued an appeal to the inhabitants of that great city to assist in the prevention of diphtheria. It is claimed that during the last 14 years 25,678 deaths from diphtheria have been prevented, and this is mainly due to the use of antitoxin. The average annual death-rate from diphtheria before the introduction of antitoxin was 136 per 100,000 of the population. During the 14 years that antitoxin has been applied the average annual death-rate from diphtheria only amounts to 36 per 100,000 inhabitants. Still the sanitary authorities are not satisfied. They maintain that practically there should be no deaths from this cause, as antitoxin, if given in proper doses and at the proper time, will cure the disease, while the immunising dose will prevent its development if taken in time by those exposed to infection. The deaths that still occur are attributed to ignorance, carelessness, and neglect. Sometimes this may be the fault of the medical attendant, but in the vast majority of cases the parents are the guilty parties. The chief difficulty is to persuade parents not to neglect what appears to be an ordinary sore-throat. Thus, in two schools 11 children were found with diphtheria bacilli in their throats. The bacteriological examination of swabs from the throats should be the common practice; and if the medical attendant will not do this, or the patient cannot afford to give the necessary fee, the Chicago Health Department physicians undertake the examination gratuitously. Further, no less than 28 free antitoxin stations have been established in various districts. The remedy, therefore, is close at hand and gratuitous for all. If lives are still lost, it is simply because the persons concerned do not avail themselves with sufficient promptitude of these advantages. According to the experience acquired during the last 14 years at Chicago, it is stated by the Health Department that recovery is certain if antitoxin is given the first day the disease is manifest. Should this be delayed to the second day the patient in nearly all cases will be saved. Even on the third day most children will recover. But if the antitoxin is not given before the fourth day, then there will be many deaths. After the fourth day antitoxin does little or no good. When given on the first day, 2000 units generally suffice. On the third day 5000 units are required, and on or after the fourth day 10,000 units are rarely of any service. As all that is necessary can be obtained gratuitously, poverty is no excuse for neglect. The State of Illinois supplies all medical practitioners with antitoxin free in exchange for a filled-up form to facilitate the furnishing of the demographic statistics. The penalty for not supplying these details concerning the case treated is the refusal to give any more antitoxin. Culture outfits for collecting samples from suspected throats to be bacteriologically examined are kept at all the police stations. Therefore they can be promptly obtained, and there is no loss of time in the analysis when once the samples are in the hands of the health authorities. Thus, the bacteriological diagnosis is quickly obtained and the proper life-saving measures can be taken at once. All that is needed is intelligent action on the part of the parents or guardians of the patient. This organisation and the excellent results attained, even amongst such a mixed population as that of Chicago, merit to be studied and imitated, which is certainly the sincerest form of flattery.

THE SPECIFIC DIAGNOSIS OF PULMONARY TUBERCULOSIS.

IT is now a platitude to state that the earlier the stage in which pulmonary tuberculosis is diagnosed the greater are the chances of success in treatment. A large amount has been written in reference to the means at the disposal of the physician to assist him in arriving at a conclusion apart from actual physical examination of the patient, for in a large number of the early cases the physical signs are indefinite and would not by themselves justify a positive diagnosis. It is, therefore, of the highest importance that careful and repeated investigations should be made into the reliability of the auxiliary methods of diagnosis which are employed by the worker in the laboratory in collaboration with the physician at the bedside. We publish this week an instructive paper on this subject by Dr. A. C. Inman, the superintendent of the laboratories of the Brompton Hospital for Consumption and Diseases of the Chest. He gives a valuable summary of the work accomplished by other observers and adds some interesting results of his own observations. The value of the detection of tubercle bacilli in the sputum is generally recognised. The Ziehl-Neelsen is the method that is most usually employed, but Dr. Inman recommends the antiformin method of Uhlenhuth and Xylander as being superior to all others. The examination of the blood for tubercle bacilli has not yielded uniform results in the hands of different observers, and is not likely to be of value in ordinary clinical work. Dr. Inman draws attention to the presence of the pathogenic bacilli in the stools of tuberculous patients. Of 26 adults 18 had tubercle bacilli in the sputum, and of these 16 had tubercle bacilli in the fæces. He suggests that the

appearance of the bacilli in the stools of early cases of pulmonary tuberculosis, in the absence of intestinal tuberculosis, results from the swallowing of sputum secreted in an open tuberculous focus in the lungs. This may be of value in the case of those patients who habitually swallow their sputum. Especial interest attaches to Dr. Inman's remarks on the tuberculin test in tuberculosis. It was at one time thought that a positive reaction to tuberculin indicated active tuberculosis, and that therefore energetic treatment was necessary. The observations of investigators from various countries indicate that this conclusion must now be modified. With regard to von Pirquet's cutaneous reaction, Dr. Inman repeats the opinion that has been widely expressed—namely, that the reaction is of value and is eminently specific in the case of young children, but it may only show the presence of latent tuberculosis in adults, for 70 per cent. of apparently healthy ones give a positive reaction. The same remark applies to the ophthalmo-reaction. Further, a negative reaction does not prove the absence of active tuberculosis. In regard to the subcutaneous tuberculin test Dr. Inman speaks with no uncertain voice. He considers that little importance is to be attached to the reaction at the site of inoculation, and as regards the febrile reaction he believes that it may now be definitely affirmed that it is not specific. On the other hand, he holds to the view that the focal reaction in the lungs is specific, and that consequently a careful physical examination of the lungs is demanded. This once again emphasises the importance of a close collaboration between the physician and his colleague in the laboratory. The old dictum that in order to arrive at a correct diagnosis in a supposed case of pulmonary tuberculosis there must be present an assemblage of signs and progression of symptoms is as true to-day as ever. Dr. Inman has made an extended research into the diagnostic value of the opsonic index. He insists that unless the opsonic index falls well outside the normal limits no deductions should be drawn from a single observation. This is of importance, as sometimes it is sought to arrive at a conclusion from one examination. The method he advocates is to examine the blood before and after walking exercise. He draws attention to the fact that the amount of exercise performed may be insufficient to activate the serum, but he considers that the physician alone must determine whether a second estimation after increased exercise is desirable. For Dr. Inman's classification of his results we refer our readers to the original paper, but his method undoubtedly seems to afford a valuable and reliable addition to the auxiliary measures for diagnosis in cases of doubtful tuberculosis. From time to time it is wise to take stock of methods, both clinical and laboratory, which have been in use for some time. New observations necessitate that old opinions should be abandoned or modified, and it is particularly with this object in view that articles like the one to which we have drawn attention are to be welcomed and carefully studied.

LARGE INCISIONS.

THE most suitable length of an incision is not always easy to determine. On the one hand, the incision should be sufficiently large to enable the surgeon to carry out fully what is needed, for nothing is more embarrassing than to have to operate through too small an incision, and the damage to the tissues caused by undue stretching may more than counterbalance any good resulting from the smallness of the skin wound. A long incision, if aseptic, takes no longer to heal than one which is small. On the other hand, an incision may be too long; the least important argument against a long wound is the unsightliness of the scar, though this may be of some moment if it is on a part of the body exposed to view. There are other and more obvious objections against an incision unnecessarily long, and these have been put forward in a letter from a correspondent in this issue of THE LANCET. He points out that in abdominal operations a long incision means much exposure and chilling of the abdominal viscera, and this may suffice to turn the scale against the patient in a serious case. In any laparotomy the length of the incision must depend on the condition present, but, other things being equal, the smaller the incision the better, for, in addition to the reasons already mentioned, certainly a small incision is less likely to be followed by a hernia.

THE OXIDATION OF PHENOL BY CERTAIN BACTERIA IN PURE CULTURE.

AN interesting communication was read at a recent meeting of the Royal Society in which Messrs. Gilbert S. Fowler, Edward Ardern, and William F. Lockett announced that in the course of their investigations on the effect of various antiseptic substances on bacterial sewage filters, they had observed that solutions of pure phenol could be oxidised on filters of this description. The phenol apparently exerted a selective action on the bacteria present in the filter, only three or four types of organism appearing in the filtrates. Of these, about half were liquefying organisms identified as B. liquefaciens fluorescens. At first it was thought that the main non-liquefying or extremely slowly liquefying organism was B. fluorescens non-liquefaciens, on account of the apparently fluorescent yellow colonies it produced; subsequent investigation showed that this was not the case. Dr. E. J. Sidebotham, of the Public Health Laboratory, Manchester, identified the chromogenic organism as a non-motile bacillus, no cilia, occurring often in pairs, no chains. In general the characteristics appear to be similar to those of B. helvolus (Zimmermann), which in gelatin forms a button-like growth of a Naples-yellow colour. On agar also it produces a thick Naples-yellow growth, and on potato there develops an abundant yellow expansion. Evidence was obtained showing that a pure culture of the organism was capable of oxidising phenol, whilst no change was noted in the phenol content of solutions containing "dead" cultures. Similarly, no change was observed in the phenol content of solutions of pure phenol. Experiments are being carried out to determine the exact effect upon the oxidation of phenol by this organism, and by the addition of other nutrient substances, one experiment having shown that the addition of broth accelerated the action. Researches have also been in progress on the bacterial oxidation of sulphocyanates, which appears to be more complex and certainly less rapidly effected than the oxidation of phenol, inasmuch as when a mixture of the two substances is submitted to bacterial oxidation the phenol is invariably the first to disappear.

Mr. Benjamin C. Broomhall, F.R.C.S. Eng., L.R.C.P. Lond., has been granted the Royal licence and authority to accept and wear the Third Class, First Division, Imperial Chinese Order of the Double Dragon, which has been conferred upon him by the Emperor of China in recognition of valuable services rendered.

WE published last week a paper by Dr. James McIntosh and Mr. Paul Fildes on the Theory and Practice of the Treatment of Syphilis with "606." The paper had the following subtitle: "From the Bacteriological Laboratory, London Hospital—Dr. W. Bulloch" (as given in the contents page of THE LANCET). By a mistake Dr. W. Bulloch's name was omitted from the footnote to the paper in the body of the journal.

STERILISATION OF WATER ON A LARGE SCALE BY MEANS OF ULTRA-VIOLET RAYS.

Methods of Industrial Water Sterilisation.

THERE are two problems of industrial water sterilisation. The first one consists of obtaining water perfectly free from germs—that is to say, absolutely sterile. The second problem is that of obtaining water which is good for public distribution as drinking water, which does not present any danger of acting as propagator for infectious maladies which, according to modern hygienic theories, are likely to be spread by certain microbes living in the water. Typhoid fever and cholera, which are supposed to be propagated by water, may be mentioned particularly.

The former problem—that of obtaining absolutely sterile water—presents itself chiefly in its application in medical practice, surgery, gynæcology, &c. This problem has been commonly solved in the following manner: 1. Heating the water to high temperature during a considerable period, in some cases even under high pressure. 2. Adding to the water chemical products, such as carbolic acid, and during later years treatment with ozone.

The latter problem—namely, that of producing a drinking water for public distribution which will not propagate maladies—has been most commonly solved by more or less frequent filtrations of the water through sand filter-beds of various density. These filtration plants keep back most of the microbes, and give a relative security to the inhabitants of a town where such system is used. Another process has been frequently advocated in the last few years—viz., adding to the water certain chemical products, such as salts which form precipitates; chlorine, which in itself is a strong bactericidal product; or oxidising agents, the principal of which has been ozone.

Filtering plants have had a very wide application in all countries; there are, however, a number of important disadvantages to their use. The first cost of such a system is very high, owing to the large area necessary on account of the slow speed at which the filtration must be carried on in order to be effective. Even under these conditions the action is not absolutely certain. The systems which advocate the addition of chemicals for sterilising or, to be more accurate, for disinfecting water, have not had general approval, due largely to the aversion of the public to anything being added to drinking water.

Sterilisation by the ozone process has been tried on a very large scale in different cities; nevertheless only a few installations have been made. One of the disadvantages of this system is the disagreeable taste which ozone gives to the water, and which only disappears after the water has been standing for a considerable time. Another objection lies in the difficulty of producing ozone without at the same time producing nitrous acids, the presence of which absolutely condemns water for drinking purposes. The first cost of the ozonising plants is extremely high, while, on account of the intelligent attention required, subsequent supervision is costly.

All these different processes, whether for dealing with small or large quantities of water, have found a very serious competitor in the methods of treatment employing ultra-violet rays, it having been demonstrated that sterilisation by means of ultra-violet rays is not only safer than by any other method, but is also infinitely simpler and cheaper.

Production of Ultra-violet Rays.

The physicist has known the ultra-violet rays for a long time; he produced them in his laboratory by different methods, principally the carbon bisulphide lamp or the arc between metal electrodes. The first ultra-violet rays which were produced industrially were in the apparatus of Professor Finsen for the treatment of lupus and other maladies, Finsen using for his purpose the arc between metal electrodes, or a series of discharge gaps constructed of iron or other metal. These sources of ultra-violet rays are, however, complicated, and have scarcely found application for other purposes than for those indicated by Finsen himself.

The quartz mercury vapour lamp, however, represents the first really convenient source of ultra-violet rays, this lamp being similar to Finsen's, in so far that the electric arc is produced between metal electrodes, these in this instance being mercury. This mercury arc has been studied particularly by Arons and by the American engineer, P. Cooper Hewitt, the latter's work resulting in the development of the well-known Cooper Hewitt lamp, which consists of a long tube, and has been largely applied for general illumination and photographic purposes.

An advance was made in the design of mercury vapour lamps when Schattner and Kuech enclosed the mercury arc in tubes of fused rock crystal whereby they obtained a very strong source of ultra-violet rays. The presence of these rays was, however, a disadvantage for an illuminating lamp, the rays themselves being injurious to the eyes. The tube of the Cooper Hewitt lamp is manufactured of glass, which is a complete absorbent of the ultra-violet rays, these being produced in the interior of the tube. It is on this account that the light obtained from these lamps is in no way harmful.

Quartz mercury vapour tubes were first applied exclusively to illuminating lamps, it being well understood that the tubes were enclosed in glass globes so as to protect the public against the enormous quantity of ultra-violet rays which passes through the fused rock crystal, of which the tubes themselves are made. Such quartz mercury vapour lamps are being made at the present time by the Westinghouse Cooper Hewitt Company in London and Paris, and by the Quartzlampen Gesellschaft in Hanau. The former company has studied jointly with Messrs. von Recklinghausen, Henri, and Helbronner the application of this mercury vapour lamp (known as the Westinghouse silica lamp) to other than illuminating purposes. These studies began with the particular application of the ultra-violet rays to the sterilisation of milk and water. This work has since been taken up in a good many other laboratories, it now being a question of almost general knowledge that dangerous microbes contained in water are killed with quite remarkable speed by the means of the ultra-violet rays emitted.

Water Sterilising Apparatus by Means of Ultra-violet Rays.

The work done in this matter has enabled the Westinghouse Cooper Hewitt Company to produce water sterilising apparatus for different applications. The first apparatus, which provided a continuous supply of sterile water at the rate of 132 gallons per hour, was referred to in THE LANCET of April 2nd (p. 937) and May 14th (p. 1390), 1910, under the heading of "Practical Sterilisation by Means of Ultra-Violet Rays," and need not be again referred to.

It may, however, be mentioned that another apparatus, producing about the same quantity of sterilised water, has been put on the market. This, however, operates on a different system, in so far that the lamp is submerged, it being claimed that a greater number of the rays emitted by the lamp are utilised for the purpose of sterilisation. It must, however, be borne in mind that the normal working of the lamp is seriously modified by the chilling effect of the water, on account of which there is an infinitely lower production of rays that is not at all compensated by the better utilisation of those which are produced. The chief disadvantage, however, is that the luminous tube becomes gradually coated with scale from the salts contained in the water, which scale renders opaque the otherwise transparent tube and prevents the ultra-violet rays from entering the water, in consequence of which sterilisation is arrested.

The sterilisation of large quantities of drinking water for public water distribution has been the object of numerous tests, in which well-known investigators have been interested.[1] Experiments to test the efficiency of the apparatus for this purpose were made by artificially polluting the water which entered the apparatus, the lamps being suspended above the water, maintained at a short distance from the surface by means of floats. These experiments also showed in a striking manner the importance of having the water violently agitated, and this experience has been used in the construction of new apparatus. These early experiments showed that

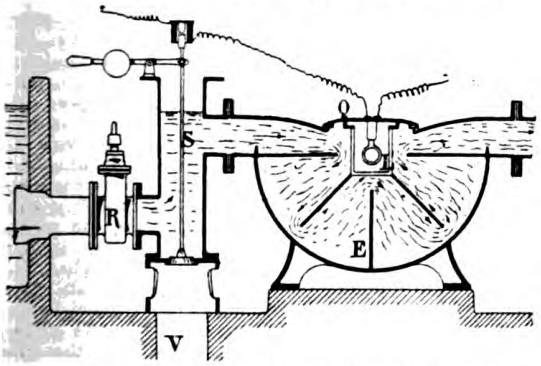
[1] See Comptes Rendus de l'Académie des Sciences, April 11th, 1910. Stérilisation de Grandes Quantités d'Eau par les Rayons Ultra-violets. Note de MM. Victor Henri, André Helbronner, et Max de Recklinghausen. Note presentée par M. Dastre à l'Académie des Sciences (these experiments based on early researches at the Sorbonne University). Cernovodeanu and Victor Henri, Comptes Rendus, Jan. 3rd, 1910.

sufficient sterilisation of drinking water could be obtained with a maximum expense of 36 watt hours per cubic metre.

In carrying out their experiments Messrs. M. Henri, Helbronner, and Recklinghausen tried to increase the bactericidal action by utilising a larger number of the ultra-violet rays generated than is possible where the lamp is merely suspended above the surface of the water. It is, however, highly important that the lamp should burn in a normal manner—that is, under the same conditions as to temperature, &c.—as in illuminating outfits, in which case the light efficiency of the lamp can be checked by testing the current and voltage. For the efficient operation of the quartz lamp it is necessary that the luminous tube should be at a high temperature (about 800° C.) If the lamp is artificially cooled, either wholly or in part, as is the case when it is submerged in running water, this high temperature cannot be obtained, and the light efficiency of the lamp is seriously reduced. It may be mentioned that the lamp for 110 volt circuit, such as we have in the small Westinghouse steriliser already described, should be adjusted to 75 volts across the tube, and in the case of the 220-volt lamp, 150 volts across the tube. The normal current of 3½ and 3 ampères respectively is obtained after 15 minutes' running; the efficiency is then at the maximum. In all Westinghouse steriliser outfits the quartz lamps run under conditions corresponding to those in ordinary illuminating outfits, consequently at their highest efficiency.

In dealing with water sterilisation on the industrial scale, the Westinghouse Cooper Hewitt Company, Limited, have thought it desirable to develop a single unit, one or several of which may be set up according to the quantity of water demanded. This unit will sterilise at least 600 cubic metres (132,000 gallons) in 24 hours, and is as already mentioned, fitted with one 3 ampère 220 volt lamp.

The unit consists essentially of three parts—viz., the special cast-iron chamber (E in figure), in which the water



comes under the influence of the ultra-violet rays; the special box with cut rock-crystal windows, into which the lamp is fitted; and the special automatic deviating valve, which ensures that no water shall pass through the sterilising chamber at such time as the lamp is not in operation. The chamber (E) through which the water passes is fitted with several baffles for directing the flow. These serve the purpose of thoroughly stirring up the water, which, as already pointed out, is necessary for the proper treatment and brings the full quantity of water under the direct influence of the light on three distinct occasions. The lamp-box (I) makes a water-tight joint with the containing vessel (E), being held in position by means of four bolts with wing nuts (O); the box itself forms an obstacle in the path of the water. The three sides of this box in the path of the water are fitted with windows of cut rock crystal which provide free passage to the ultra-violet rays emitted by the lamp, through which they pass into the water flowing in the chamber. The deviation valve (V) is placed between the supply and the steriliser apparatus, and consists of a double T-piece fitted with a mushroom valve at the lower end, this valve being held closed by means of a solenoid (S) energised by the current flowing in the sterilising lamp. Should the current be cut off for any purpose this valve would be immediately opened and the water would cease to pass through the sterilising chamber. This automatic deviating valve can readily be fitted with a bell or luminous signal, so as to attract the attention of the inspector of the plant.

On entering the apparatus the water passes through the supply valve (R) and over the deviating valve (V) into the chamber (E). The flow is directed against the first window of the box (I) by means of a baffle, is then sent to the periphery of the chamber and back again to the second or horizontal window; thence it passes back to the periphery of the chamber round a further baffle to the third window, thus coming under the direct influence of the ultra-violet rays on three distinct occasions. In the event of the lamp not being in operation, the deviating valve (V) would be open, through which the water would pass. In this way it is assured that nothing but sterilised water can be distributed to mains.

The Westinghouse steriliser of this type (although in a somewhat less perfected form) has been in service for a considerable time at the Competitive Exhibition for Sterilising Apparatus at Marseilles. The following table shows the results of a few of the tests which have been made with this apparatus:—

Results of Tests with Water Exposed to Ultra-violet Rays.

Experiment No.	Cubic metres water per 24 hours.	Watt hours per cubic metre.	Before steriliser.			After steriliser.		
			B. coli per litre.	Germs per cubic centimetre.	Mould per cubic centimetre.	B. coli per litre.	Germs per cubic centimetre.	Mould per cubic centimetre.
1	More than 600	Less than 26	—	158 174 148	—	—	0 2 2 0 0	8
4	Do.	Do.	100 to 200	220 260	—	0	2 2	—
7	Do.	Do.	—	22 18	2	—	0 4 0 0	2 10
10a	Do.	Do.	500	36 36 40	2	0	0 0	3
12a	560	28	80	22 20 18 24 16	—	0	0 0 0 0 0·5 0 0	3 1·5
12b	More than 600	Less than 26	50	48 52 44	2	0	0 0 0 0 0 0	6
13	Do.	Do.	50	24 30 14	—	0	0 2 6 0	—
14	Do.	Do.	200	30 38 20	—	—	10 6 0 4 1	2
18	Do.	Do.	500 to 1000	43 60	—	0	0 0 0 0 0 1	—

From this table it will be noted that the quantity of water passed through the apparatus was in nearly every case more than 600 cubic metres per 24 hours. At certain periods of the tests an even greater flow of water was available, and even under these conditions the bacteriological results were no less satisfactory than those cited above. This table shows that the water leaving the apparatus was in the majority of

cases sterile—that is, showed an entire absence of germs—and in no case did tests reveal more than 10 germs per cubic centimetre; on no occasion even when testing with 200 cubic centimetres were any B. coli found. The water which has been treated in apparatus of this description can therefore be safely classified amongst the "perfect" waters, according to Miquel's definition, whilst the water which was fed into the apparatus could scarcely be called potable, it being far too rich in B. coli.

The presence in some cases of a greater quantity of mould in the water after passing through the apparatus is due to the lack of protection of the opening from which the test-water was drawn, whereas the valve between the supply and the apparatus was well protected against dust and wind. The water with which the apparatus was fed during the Marseilles tests was clarified by the installation of roughing filters and prefilters of the system "Puech and Chaball, Paris." The installation produced a perfectly clear water from the very muddy supply of the river Durance. This water was in most cases quite opaque, even through a column 1 metre long.

The above tests, carried out by independent authority, have clearly demonstrated the possibility of producing perfect drinking water for public distribution with consumption of 26 watt hours per cubic metre, single apparatus being capable of dealing with fully 600 cubic metres in 24 hours. In view of the extreme simplicity of the apparatus and this low power consumption, it would appear that there is a wide future for this new system of sterilisation.

THE CORONERS' LAW AND DEATH CERTIFICATION (AMENDMENT) BILL.

THE procedure by which in this country deaths from unnatural or unknown causes are investigated has, it is notorious, given rise to much dissatisfaction. Complaints and criticisms extending over several years were ultimately brought to a head and the various authorities concerned have held inquiries and have proposed schemes of reform. It seems likely that in the near future these proposals will constitute the basis of legislation, and it is therefore of importance that the medical profession should scrutinise them closely, and, if required, should exercise its influence in such a way as to ensure that the community shall receive the full benefit of medical knowledge as it exists at the present day.

We may briefly recapitulate the steps which have been taken during recent years. In October, 1906, the London County Council passed a series of resolutions suggesting amendments in the laws relating to death certification and coroners' inquests. In 1908 a Departmental Committee was appointed by the Home Office to inquire into the law relating to coroners and coroners' inquests, and in December, 1909, this committee issued a report containing a number of recommendations.[1] In April of this year Sir William Collins introduced a Bill in the House of Commons "to amend the Law relating to Coroners' Law and the Certification and Registration of Deaths and Burial." Recently the London County Council (on which body there is at present not a single medical man) passed a further series of resolutions dealing with coroners' affairs, and resolved, subject to certain amendments, to support Sir William Collins's Bill, and to urge the Lord Chancellor and the Home Secretary to secure facilities for the early passing of the Bill. Sir William Collins's Bill—amended possibly in certain particulars—may therefore be the basis of forthcoming legislation, whatever the whirligig of politics may bring about in the next few days, and it is accordingly the provisions of this Bill that should be examined.

The Bill has already aroused strong opposition owing to the proposal it contains to make it obligatory for a medical practitioner personally to inspect a body before giving a certificate of death, but without making any provision for the payment of a fee. For the moment, however, we wish to confine our remarks to the clauses dealing with coroners, which have not yet received, we think, the attention from the medical profession their importance deserves. The Bill does not by any means follow the recommendations of the Departmental Committee, and in this matter we are bound to observe that, while fully recognising the high abilities and great experience of Sir William Collins, we are not aware that he has had an experience of the coroners' courts so large as to justify his setting aside recommendations arrived at by the committee after prolonged inquiry. The Departmental Committee, for instance, found that there was justifiable dissatisfaction in the medical profession with the scale of fees in the coroners' court and with their mode of allocation, and recommended a new scale. It also advised that medical officers of institutions in which deaths occurred should no longer be deprived of their fees. Neither of these recommendations finds a place in the Bill.

It is, however, Clause 5 of Sir William Collins's Bill which calls for the most urgent criticism. This runs as follows:—

> No person shall be appointed a coroner unless he be a practising barrister of not less than five years' standing, or a solicitor of not less than five years' standing, or a registered medical practitioner who is also a barrister or a graduate in law of a University in the United Kingdom.

A proposal which seeks to place the medical man at a disadvantage, as compared with a member of the legal professions, in a matter admittedly closely pertaining to medicine, requires strong reasons for its justification, and it becomes necessary to review the functions which are discharged by the coroner, and to determine his sphere of usefulness in order to ascertain whether any such reasons do, as a matter of fact, exist.

The office of King's coroner affords an instance of an institution which, created many centuries ago for a specific purpose, has gradually undergone a complete change of function, but without having satisfactorily adapted itself to that change of function. The coroner dates back at least to the twelfth century, and was originally a revenue officer of the Crown. It was his duty to take possession of the revenues of the king. He had to find out criminals and confiscate their goods; to take possession in the name of the King of wrecks and stranded whales; and to seize treasure trove, an obligation which still remains. He came to inquire into deaths for the purpose of discovering whether the deceased was an outlaw or a suicide, as in that case his property escheated to the Crown. In the case of a death caused by some animal or inanimate thing he had to assess the value of the deodand which was forfeited to the Crown as compensation for the loss of a subject. Otherwise he had no interest in the matter, for pathology and vital statistics were still to come. As security against appropriation of the revenues so collected he had to own land "in fee sufficient," a condition which must still be complied with. This close connexion with judicial matters probably explains how it is that the office has so largely fallen into the hands of lawyers. But with the gradual evolution of society the character of the duties of the coroner changed. Escheat disappeared, revenues were collected by other officers, deodands were abolished by statute in 1846, and the holding of inquests on Royal fish or wrecks was expressly excluded by the Coroners Act of 1887. At the same time other reasons for inquiring into deaths came into existence. Accurate scientific information was required for the purpose of the Registrar-General's annual returns, for legislation connected with public health, industrial poisoning, food poisoning, infant mortality, factories, insurance, compensation, and many other matters of the highest public importance. The advantage in having a medical man to inquire into deaths from unnatural or unknown causes was to some extent recognised, and thus it has come about that in recent years the medical man has partly displaced the lawyer in the office of coroner, though the majority of coronerships in England and Wales are still held by solicitors.

A coroner is by 50 and 51 Vict., Ch. 71, required to hold an inquest where there is reasonable cause to suspect that a person has died a violent or unnatural death, or where there is a sudden death from causes unknown. Inasmuch as only cases possessing some sensational interest are regularly reported in the public press, considerable misapprehension exists among those not familiar with the coroner's court as to the character of the bulk of the work which is performed therein. Murders and manslaughters are reported in full, and as a result appear to form a much larger proportion of a coroner's inquiries than is

[1] THE LANCET, August 21st (p. 557), 1909, and April 2nd (p. 942) and 9th (p. 1009), 1910.

actually the case. Out of 37,092 inquests held in England and Wales in 1908 there were only 291 verdicts of murder and manslaughter together, or less than 0·8 per cent. The total number of persons actually tried for murder was only 67. It is generally believed that the coroner plays an important part in aiding the detection of these crimes, but his value in this respect is probably over-estimated. Whenever there is reason to suspect that crime has been committed, thorough and independent investigation is always made by the police, and indeed the coroner's own inquiries are usually made by the police, inquests being frequently adjourned in order to give them time to finish their investigations. The magistrate's inquiry is quite independent of the inquest, and if he commits for trial the facts are again recited before the higher tribunal. Recent events have furnished a striking illustration of the cumbersomeness of our procedure in requiring two preliminary inquiries before trial in cases of murder, with the consequent additional expense to the State and inconvenience to witnesses, counsel, and others concerned, who are required to make afresh statements already fully examined under oath at another court. There can be little doubt that the coroner's jurisdiction in this respect might be dispensed with, without detriment to the community.

On the other hand, the deaths of infants or children from such causes as inattention at birth, malnutrition, overlying, neglect, exposure, improper feeding, want of medical treatment, &c., although enormously more numerous, attract but little attention in the public press, and their frequency is seldom realised, yet out of the 37,092 inquests held in England and Wales in 1908, no less than 9935 were upon the bodies of children under seven years of age. This figure, of course, includes "natural deaths," but in a large proportion of so-called natural deaths conditions of neglect or ignorance are antecedent causes, though juries are loath to find so except in flagrant cases. It is in inquiries of this nature that the coroner has the greatest opportunity of performing public service. Neighbours are usually present, and any remarks he may make are repeated outside to a wider circle than those actually present in court. Thus his court may be made a centre for distributing knowledge among the ignorant poor. Whether it be in reference to medical treatment, suitable clothing, overlying, breast-feeding, or other kindred matters, a coroner can exercise a valuable influence tending to the decrease of infant and child mortality, though most of this highly desirable work passes unreported and almost unnoticed; not entirely unnoticed, however, for the influence of the coroner can be traced in more than one clause of the Children Act of 1908. There is, of course, no legal obligation upon a coroner to undertake these duties, but most of the medical coroners do act in this way, and everyone will admit the desirability of such action. The point does not need labouring that the intimate knowledge of child life and health requisite for this purpose is far more likely to be found in the medical man than in the lawyer.

Another direction in which coroners' inquests are, or should be, of great value is in the obtaining of accurate information for the purpose of the Registrar-General's annual returns. It must be remembered that not only are the cases which come before him involved, but that the attitude of the coroner will have an effect upon the certificates of all the medical practitioners in his district. Here, again, the medical man must necessarily have an advantage. It is not often nowadays that a verdict so remarkable as that quoted by the Select Committee of 1893 is recorded—viz., that "Deceased died from stone in the kidney, which stone he swallowed when lying on a gravel path in a state of drunkenness," though many verdicts of but little greater scientific value are still recorded by non-medical coroners. In a quite recent inquest on a person who had died with an effusion of blood from the mouth, the medical witness, in the absence of a post-mortem examination, declined to express an opinion as to the cause of death. Pressed to answer the question, he still adhered to his attitude. The coroner then turned to the jury and told them that although he was not a medical man he had had 30 years' experience, and he would inform them of the cause of death. It was rupture of a blood-vessel, and a verdict to that effect was accordingly returned. It might be said that the lawyer coroner can supply his deficiencies from the medical evidence placed before him. But it is clear that he must have medical knowledge to appreciate that evidence and to examine the witness upon it. He must also be able to distinguish essential from non-essential. At present the non-medical coroner is too apt to attach undue importance to such terms as "coma" or "syncope." "Convulsions" figures largely as a cause of death in the coroners' courts, although the term is one the use of which is expressly deprecated by the Registrar-General.

On behalf of the lawyer's claim to coronerships it has been urged rightly that his knowledge of law is of value, and that he has had experience of the laws and method of taking evidence. We think, however, that it is easier for a medical man to acquire in a short space of time the necessary knowledge of law than it is for the lawyer to acquire the medical knowledge without going through the usual hospital training.

One point more must be considered. Sir William Collins's Bill provides that a coroner may order a post-mortem examination to be made, and if he is satisfied in this way that death was due to natural causes he need not hold an inquest. This is a desirable reform in the present procedure, but seems to render it more imperative that the coroner should be a medical man. The interpretation and assessment at its proper value of a medical report is often a difficult matter, and to leave it in the hands of a layman may be a highly dangerous experiment. In his preliminary inquiries a coroner has no power to compel answers to questions, or to summon witnesses, or to examine them on oath. He must act on his own unassisted judgment. In 1908 there were 19,054 preliminary inquiries which were not followed by inquests, and there were 14,184 inquests in which verdicts of natural death were found. In every one of these cases the medical statement or evidence was presumably the determining factor, and yet the bulk of them were probably investigated by men who had never seen a post-mortem examination made.

If, instead of having existed from the twelfth century, we could imagine coroners now being created for the first time, it is probable that we should never think of appointing anyone but a medical man to inquire into a matter so essentially medical as the cause of death, though he would most likely be required to have had special experience, just as at the present moment the public health service is in the hands of medical men but with special experience. Nor is the cause of death the only medical matter which may be at issue: the whole domain of medicine may come under review in the coroner's court. The coroner should be capable of understanding and properly weighing evidence as to whether an infant was born alive or not, and whether it was mature or not. He may have to determine whether an operation was justified, and whether it was efficiently performed. He may be called upon to decide whether certain medical treatment was appropriate, or whether an anæsthetic was administered with due precautions. He must have a knowledge of the effects of poisons. He must be familiar with the symptoms and results of all forms of insanity. Medical evidence will be given before him on such matters and he has to interpret it to a jury.

It is only custom which has blinded us to the anomaly of a lawyer holding these inquiries. The office is essentially of a medical character. Sir William Collins's Bill contains much that is of value, and we trust it may be found possible to delete or modify the unsatisfactory provisions before it becomes law.

THE WATER-SUPPLY TO SOUTHEND.

TWENTY-FIVE years ago Southend had a resident population of 10,000 or 12,000; to-day its 60,000 permanent inhabitants are annually increased by a like number of summer visitors, the average consumption of water for all purposes being 32 gallons per head. Such a rapid increase of population in a district so unfavourably placed geologically for obtaining a pure and abundant water-supply is probably unequalled in the United Kingdom. A glance at a geological map shows that the great mass of the London clay covers the entire district to a depth of from 300 to 500 feet, with the exception of Grays and Purfleet. Beneath the clay are the lower London tertiaries of varying depth with the Thanet sands resting on the chalk, which is the principal water reservoir for South-East England. The rain falling

on any part of Essex south of a line drawn from Colchester, through Chelmsford, to Buntingford, drains off through natural surface channels, and is unavailable as the source of a large supply, though, of course, numbers of shallow wells sunk in pockets of gravel occur locally. Only rain falling north of this line, or where the chalk outcrops at Grays and Purfleet is available for Southend, and must travel long distances through the chalk.

At Grays and Purfleet water is obtainable in abundance, its character agreeing exactly with that obtained from the chalk on the south side of the Thames. The chalk, however, descends rapidly on all sides save the south, since at very short distances from the outcrop the chalk lies at a depth of 300 feet. The only water obtainable in this district is from the chalk or the overlying Thanet sands. The chalk is very compact and free from fissures, and does not yield water readily, and the Thanet sands are of so fine a texture that unless the pumping is comparatively slow sand comes up with the water and is a source of serious trouble. Some of the beds lying between the base of the London clay and the upper surface of the chalk yield water, limited in amount, but often of a very objectionable character in consequence of its containing large quantities of magnesium and calcium sulphates, which render it excessively hard and quite useless for drinking or any other domestic purpose. In sinking wells in the locality this water has to be effectually stopped out or the whole yield is rendered unusable.

Notwithstanding these difficulties, the water company which supplies the borough of Southend, the urban district of Leigh, and portions of the adjoining rural districts, has always provided an abundant supply of water to the rapidly increasing population. At first Southend alone was supplied from two borings nearly 900 feet deep situated in the parish, but as the population increased more and more wells were sunk, two or three miles apart, until they now number 21 and extend to Billericay, some 20 miles away. At the same time, the area of supply was extended so as to include parishes in which the wells were situated and others along the route of the mains. These wells vary in depth from 300 to 900 feet, and whether the water is drawn from the Thanet sands or from the chalk it is identical in character. It is very soft, and of the highest degree of organic purity. The last well sunk yielded water containing the constituents as under :—

	Grains per gallon.
Calcium carbonate	1·2
Magnesium carbonate...	0·4
Sodium carbonate	21·0
Sodium sulphate	9·1
Sodium chloride	22·7
Silica, &c.	0·9
Total ...	55·3

This analysis has been confirmed in THE LANCET laboratory, and in an experiment in which a strip of lead was placed in the water there was no action. This may be taken as typical of the water from the majority of the wells, though some contain a little more calcium salts. All the wells yield a very pure slightly alkaline saline water, of the kind which when it is found on the Continent is charged with carbonic acid gas, bottled and sent over here as a table water, and lauded for its virtues and for its purity. There is no doubt that water of this character, containing very little lime salts and a little sodium carbonate and chloride, is very palatable and very wholesome.

Only limited areas are supplied from any one well. The rising mains deliver into one of two very large covered storage reservoirs situated on commanding eminences, and these reservoirs supply by gravitation the various service reservoirs placed near the centres of population. Pollution of water derived from such sources and distributed in this manner may be said to be impossible, the supply being constant and not intercepted by domestic storage cisterns, which are a frequent source of danger. Every well is sunk through some 300 to 400 feet of London clay, which is of the most impervious character, and is lined throughout the sunk portion with iron cylinders above and brickwork set in cement below, and with the exception of one or two of the older wells all are in the open country, far from any habitations. Samples from three different parts of the district are submitted quarterly to chemical and bacteriological examinations by Dr. J. C. Thresh at the London Hospital, and once a year all the wells are examined and samples from each submitted to bacteriological examination.

Every care is therefore taken to provide Southend with a water absolutely beyond suspicion, and the rapid increase in population, as well as the natural disadvantages of site, have been perfectly met. These things give a medical interest to the matter.

REPORT OF THE PUNJAB PLAGUE COMMITTEE, 1910.

A COMMITTEE appointed by Sir Louis Dane, K.C.S.I., Lieutenant-Governor of the Punjab, to inquire into the utility of the present anti-plague policy and to report on the best means in the light of recent knowledge and experience of increasing its efficacy, assembled recently at Simla. The composition of the committee was as follows :—President : The Honourable Mr. A. Meredith, Indian Civil Service. Members : Colonel C. J. Bamber, I.M.S., Inspector-General of Civil Hospitals in the Punjab ; Lieutenant-Colonel C. P. Egerton, Indian Army ; Major E. Wilkinson, I.M.S., Sanitary Commissioner of the Punjab ; Mr. C. M. King, Indian Civil Service ; and Captain C. A. Gill, I.M.S., Chief Plague Medical Officer of the Punjab. This committee has issued a most important and interesting report which is particularly opportune in that the question of rat destruction and plague prophylaxis generally has been before the medical profession in this country recently owing to the detection of plague-infected rats in certain parts of East Anglia and other places.

Results of Anti-plague Measures.

In the Punjab Province during the past three years (1906–1909), at an expenditure of over £147,235, an active prophylactic campaign has been waged against plague. One of the main objects of the committee has been to ascertain whether the results of this heavy outlay have been commensurate with the expenditure incurred. They, however, find it a matter of some difficulty to pronounce a definite opinion on the question, and before doing so they place on record two main facts which the evidence before them clearly established : (1) that plague preventive measures have been the means of saving a vast amount of life ; and (2) that the natives of India look to Government, not only to aid them, but to take the initiative in maintaining the struggle against plague.

It has also been brought home to the committee, particularly by the evidence of Indian witnesses, that the measures which have been adopted with the object of suppressing plague have induced a desire for sanitary reform on the part of all classes of the population. In addition, the plague staff have performed useful service in administering medical relief in rural areas and they have also been of assistance in fighting epidemics of cholera and malaria. Last, but not least, the constant tours of the medical officers on plague duty in infected tracts have furnished the natives of India with a tangible proof of the solicitude taken by the Government in their welfare. On these grounds alone many of the witnesses examined were of opinion that the expenditure incurred by Government in furtherance of anti-plague measures was amply justified, and the committee fully endorse the views of those who consider that the cessation of anti-plague operations would be viewed with dismay and might possibly give rise to a feeling of discontent. They therefore think that, in view of the state of plague in the Punjab and the small likelihood of its amelioration in the near future, considerable expenditure will still be necessary. Postulating this, the committee appear to have carefully scrutinised the various preventive measures that are at present being employed, and they embody certain conclusions and recommendations in a thorough and able report, drawn up by Captain C. A. Gill, I.M.S., chief plague medical officer of the Punjab, who acted as secretary of the committee.

Recommendations and Conclusions of the Committee.

The chief recommendations and conclusions may be briefly stated as follows :—

General policy.—An active anti-plague policy on the part of Government is not only necessary but should be continued.

Rat destruction.—The destruction of rats in Punjab villages by means of poison for the purpose of preventing plague epidemics not being attended with success should be

abandoned on a large scale. Systematic trapping with traps (in the ratio of 2 per cent. of population) does not reduce the rats of Punjab towns and villages sufficiently to prevent plague epidemics. To diminish adequately the rat infestation of towns and villages by means of systematic trapping presents difficulties of such a magnitude as to render it an impracticable policy on a large scale. The destruction of rats by means of poisoning and trapping on the present lines does not yield results commensurate with the expenditure incurred, and it should be discontinued. The greatest prospects of success in preventing the spread of plague by means of rat destruction consist in attacking the comparatively few localities where plague persists during the quiescent period.

Anti-plague inoculation.—Anti-plague inoculation is essentially a personal prophylactic measure, and in recommending its adoption everything savouring of compulsion or pressure should be carefully avoided. During severe epidemics of plague regimental medical officers might with advantage be temporarily employed as inoculating officers in the recruiting area of their regiments.

Village sanitation.—For dealing with plague epidemics in villages, evacuation is a most important anti-plague measure, and means are suggested in the report to facilitate its more widespread adoption. Measures directed towards improving village sanitation and domestic hygiene are of the utmost importance, and efforts should be made to give effect to such simple measures of this nature as public opinion may endorse. The erection of model houses at the headquarters of districts, the removal where possible of manure from close proximity to village sites, and an increased conservancy staff for villages are desirable measures.

Disinfection.—The disinfection of infected houses during the course of an epidemic or after its cessation is not ordinarily necessary. Disinfection as applied to the clothing and baggage of persons coming from infected areas is a valuable means of preventing the spread of plague into non-infected areas and should be carried out whenever possible. The only measures of a compulsory nature which are permissible are those demanded by public opinion and capable of being put into operation by the people themselves.

Quarantine.—Certain measures to facilitate quarantine, isolation, and refusal of access in the case of villages should be adopted. The extension to the inhabitants of towns as well as villages of legal powers to prevent the access of persons coming from infective areas is recommended. The power possessed by Commissioners of prohibiting fairs in infective localities should be more freely exercised.

Reports.—An efficient system of intelligence whereby the presence of plague is rapidly reported is of the utmost importance. Certain alterations are suggested with a view to accelerating the receipt of infection reports by civil surgeons. The present procedure in regard to the reporting of plague occurrence should be cancelled and regulations practically identical with those already in force dealing with cholera should be substituted.

Finance.—Substantial money rewards should be offered for information regarding plague occurrence during the hot weather. The organisation and training of a lay agency are most important measures, and honorary plague officers should be appointed in all districts subject to infection. The submission by Commissioners to the Inspector-General of Civil Hospitals, Punjab, of a quarterly return showing the grants-in-aid made to local bodies from provincial funds is necessary. Rat destruction operations on the limited scale recommended by the committee should be a charge on provincial funds. Plague officers should be invited to attend the budget meetings of district boards. Certain proposals in regard to the various details connected with district organisation and administration are also embodied; these, however, call for no special remarks.

From this report it appears that with regard to preventive measures opinions as to what is best have undergone considerable changes. On the advice tendered by the committee the Punjab Government have decided to give up *general* rat destruction, but to continue it in *circumscribed areas* where the disease persists in the quiescent period (viz., during the summer months), which form foci for its distribution later in the year. On the question of disinfection the committee in making the following dogmatic statement are bound to invite criticism; they say: "In the light of recent knowledge it is clear that disinfection, either by heat, chemicals, or poisonous gases, can rarely be relied on to destroy permanently the infectivity of rooms and dwellings. The committee desire to emphasise this point, as they observe that not only is disinfection in some form or other popular with the people, but in some cases district officials have lent their authority to encourage its adoption on a large scale. It may therefore be mentioned that ordinarily the only procedure of this nature that is called for in plague-infected villages is the admission of light and air into infected houses and the exposure of their contents to the direct rays of the sun."

From a financial point of view this and the other recommendations already enumerated appear to foreshadow a reduction in the cost of anti-plague measures in the Punjab. And it is encouraging to note that the question of sanitary conservancy is to be taken up more fully in villages and that responsible sanitary officials will be placed in charge of rural areas.

THE CHOLERA EPIDEMIC.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

Cholera in Russia.

THE epidemic in Russia continues to decline. The following figures are in continuation of those published in my last letter (which appeared in THE LANCET of Nov. 19th, p. 1507):—

Week ending	Sept.	11th	...	3878	cases,	2004	deaths.
,,	,,	,, 18th	...	2919	,,	1529	,,
,,	,,	,, 25th	...	2089	,,	1121	,,
,,	,,	Oct. 2nd	...	1022	,,	584	,,
,,	,,	,, 9th	...	823	,,	383	,,

The above are all "corrected" figures. For the succeeding three weeks only "uncorrected" figures are as yet available. They are as follows:—

Week ending	Oct.	16th	...	449	cases,	279	deaths.
,,	,,	,, 23rd	...	170	,,	110	,,
,,	,,	,, 30th	...	85	,,	35	,,

(The above dates are all according to the Old Style.)

The disease still lingers principally in St. Petersburg, in the valley of the Volga, in Central Asia, and Siberia. It has appeared at Vladivostok and in the Amur and Primorskaia (or maritime) provinces, on the Pacific coast. In the last named there were 196 cases and 76 deaths in the week ending Oct. 9th, 149 cases and 140 deaths in the next week, and 25 cases and 29 deaths in the week ending Oct. 23rd (Nov. 5th). These are "uncorrected" figures. The *Vratch* continues to publish week by week observations on the St. Petersburg water-supply. Of these, the following may be quoted. Of 24 samples of unfiltered water taken at the waterworks between August 30th and Sept. 2nd (Old Style), 10, or 42 per cent., contained the cholera vibrio; and of 64 samples of filtered water taken the same days 11, or 17 per cent., were also found contaminated. Out of 30 samples of water taken direct from the Neva, near its left bank, the cholera vibrio was found in no less than 22, or 73 per cent. In later observations the percentage of infected samples greatly diminished; and out of 14 samples of unfiltered water taken on Oct. 7th and 8th only 1 was found infected, while out of 34 of filtered water also only one contained the cholera bacillus. A serious outbreak of the disease occurred in October in the staff of the Penteleimon Lunatic Asylum in St. Petersburg; in the course of a few days there were as many as 41 cases of the disease here.

Cholera in Germany.

In the week ending Oct. 23rd 10 fresh cases of cholera were recorded, and on the 24th the whole German Empire was declared cholera free.

Cholera in Austria.

On Oct. 17th an imported case of cholera occurred at Trieste; the patient had left Rutigliani (near Bari), in Italy, on the 5th, had stopped seven days in Venice, and arrived in Trieste on the 13th; he was arrested as the result of a street fight, and developed symptoms of cholera in the night of the 14th–15th—i.e., nine days after he had left the infected area

in Italy. In the night of the 23–24th a child, aged 11, son of the "contrôleur" of the above prison, fell ill with cholera, and the diagnosis was confirmed bacteriologically. No other cases have occurred recently in Austria.

Cholera in Hungary.

In the week ending Oct. 22nd 28 cases and 14 deaths were recorded in 16 different places, situated in the counties of Bacs-Bodrog, Baranya, Tolna, Esztergom, Temes, and Torontal. In the week ending Oct. 29th 6 cases and 6 deaths occurred in seven different places situated in the first three of the above counties. On Oct. 21st the Hungarian Ministry of the Interior announced that the communes of Czrepaja and Klekk, in the county of Torontal, were declared "foyers de choléra"; in the former 17 cases had occurred between Sept. 22nd and Oct. 18th; and in a workman's colony at a sluice on the river 4 kilometres from Klekk 15 cases had occurred before Oct. 18th.

Cholera in Italy.

Complete information as to the recent behaviour of the epidemic in Italy has not been received here. For the week ending Oct. 26th the figures are wanting; in that ending Nov. 2nd 26 cases and 17 deaths occurred in the Province of Caserta; 6 cases and 3 deaths in that of Lecce (including 2 cases and 2 deaths at Brindisi); 6 cases at Palermo; 7 cases and 2 deaths in the Province of Rome (all at Terracina); and 8 cases in the Province of Salerno. (These figures have been communicated by the Turkish Embassy in Rome.) Sporadic cases are said to be occurring still at Brindisi, and (it is stated by the Turkish Consul in that port) the Italian journals mention the continued occurrence of cases at Massafra, Squinzano, Tricase, and Ostuni. All these places are situated in the "heel" of Italy.

Cholera in Bulgaria, Servia, and Roumania.

A fatal case of cholera was reported from Varna on Nov. 17th; the patient had arrived from Constantinople and had completed his five days' quarantine before he was attacked. No further cases of cholera have been reported from either Servia or Roumania.

Cholera in Constantinople and Turkey in Europe.

There has been a considerable extension of the cholera outbreak in this city, as shown by the following figures:—

Week ending	Oct.	24th	...	7	cases,	7	deaths.
,,	,,	,,	31st	...	8	,,	4	,,
,,	,,	Nov.	7th	...	63	,,	33	,,
,,	,,	,,	14th	...	132	,,	70	,,
,,	,,	,,	21st	...	173	,,	96	,,

These figures refer only to the civil population; the totals down to the 21st inst. were put at 477 cases and 264 deaths. At present from 20 to 40 cases are being reported daily, and the tendency is still for the figures to rise. The epidemic has no doubt been favoured by the exceptionally mild autumn and prolonged continuance of a warm south wind.

The above figures refer, as stated, solely to the civil population. But there has also been a considerable mortality from cholera among the troops. It is now established beyond doubt that the manœuvres recently held in the Adrianople vilayet have been largely instrumental in spreading cholera, if not in actually introducing it to the European provinces of Turkey and the capital. It is believed that the employment of troops from Trebizond in those manœuvres may have acted in this way. It is certain that the dispersal of troops after the manœuvres were over aided in spreading the infection far and wide. Of the behaviour of the disease during the actual manœuvres little is known. But cholera undoubtedly broke out at Adrianople itself; a serious epidemic occurred among the troops at Hademkeui (on the railway line between Adrianople and Constantinople); further cases were seen at Kirk Kilissé, Tchorlou, Kirdja Ali, and other places in the vilayet; and when the troops reached the coast of the sea of Marmara, and camped in the neighbourhood of Rodosto and Eregli, they were seriously ravaged by the disease. On Oct. 30th 4000 or 5000 of these men were put on board two ships to cross to the Asiatic coast, and during the few hours' voyage no less than 30 cases and 14 deaths from cholera occurred on one ship, while 13 cases were found on the other ship on their arrival at Touzla. The men were interned in the quarantine station at Touzla and subjected to quarantine and disinfection, but the disease continued to spread amongst them and in the village of Touzla adjoining. In the lazaret 99 cases with 69 deaths were seen between Oct. 30th and Nov. 7th, 92 cases and 57 deaths between the 7th and 14th, and some further cases and deaths in the following week. In the village a few cases occurred in each of those weeks. Between Nov. 12th and 19th as many as 25 cases with 19 deaths were recorded there. Meanwhile the outbreak at Rodosto and Eregli on the European side of the Marmara continued; complete figures have not been received, but it is certain that over 100 cases and half as many deaths have occurred there among troops and civilians, and it is possible that double or treble that number have occurred. In the capital itself many cases have been treated in most of the large military hospitals, but the figures hitherto made known are too incomplete, and furnished at too irregular intervals to be usefully quoted.

The most remarkable feature about the present epidemic in this city is the fact that the disease is present over a large proportion of the immense area that the city covers, extending from the Marmara to the Black Sea, and on both shores of the Bosphorus; that small numbers of cases continue to occur in each of the municipal divisions; and that only in one or two (such as Cassim Pasha, Fundukli, &c.) has a real "foyer" of infection formed.

On Nov. 16th, on the arrival of the Constantinople train at Salonica, a passenger was found dead in his compartment (according to the railway authorities); he had been taken ill shortly after passing the last station, where the passengers were medically examined, and died an hour before reaching Salonica. There was bacteriological proof that death was due to cholera.

Cholera in Asiatic Turkey.

In the vilayets of Erzerum and Van the epidemic continues to decline, as shown by the following figures:—

Week ending	Oct.	20th	...	23	cases,	22	deaths.
,,	,,	,,	27th	...	7	,,	4	,,
,,	,,	Nov.	3rd	...	24	,,	20	,,
,,	,,	,,	10th	...	5	,,	4	,,
,,	,,	,,	17th	...	0	,,	0	,,

In the Trebizond vilayet the disease is practically stationary. The following are the latest returns:—

Week ending	Oct.	23rd	...	23	cases,	21	deaths.
,,	,,	,,	30th	...	15	,,	9	,,
,,	,,	Nov.	6th	...	36	,,	14	,,
,,	,,	,,	13th	...	39	,,	23	,,
,,	,,	,,	20th	...	37	,,	23	,,

The totals here are put down at 639 cases and 352 deaths since the beginning of the outbreak on Sept. 16th.

A few cases of cholera have also occurred at Samsoun, at Kerassonde and Ordou, on the north coasts of Asia Minor, and at Zunguldak (port for the Heraclia mines) and neighbourhood some cases and deaths are still recorded weekly.

In the vilayet of Bagdad the infection has spread widely and caused a considerable mortality. The following returns (admittedly imperfect) have been received:—

From	Oct.	6th	to	Oct.	23rd	...	199	cases,	148 deaths.
,,	,,	24th	,,	,,	30th	...	191	,,	177 ,,
,,	,,	31st	,,	Nov.	6th	...	156	,,	140 ,,
,,	Nov.	7th	,,	,,	12th	...	18	,,	17 ,,
,,	,,	13th	,,	,,	19th	...	81	,,	62 ,,

The totals are put at 645 cases with 544 deaths for the whole vilayet. The disease has appeared not only in Bagdad but also in Kiazimieh, in Mossove, in Amara, in Samara, in Khanikin (on the Persian frontier), and many other places; and finally it has broken out at Kerbella, one of the Shiah holy burying places, where between Nov. 16th and 19th 26 cases and 20 deaths were recorded among Shiah pilgrims.

At Basra there were 13 cases of cholera and 9 deaths between Oct. 20th and 27th; 97 cases and 61 deaths between Oct. 28th and Nov. 3rd; 86 cases and 79 deaths between Nov. 4th and 13th; and 20 cases with 14 deaths between Nov. 13th and 18th. The lazaret of Basra (on the island of Salahieh in the Shatt-ul-Arab river) has also had to deal with considerable numbers of cases among Afghans, Indians, and others, and it seems possible that these persons were actually infected in the lazaret itself. Between Oct. 28th and Nov. 3rd 9 cases and 9 deaths occurred here (all Afghans); between Nov. 4th and 13th 23 cases and 15 deaths; and between Nov. 13th and 18th 4 cases with 4 deaths.

The movements of Moslem pilgrims towards the Hedjaz is now at its height, as the fêtes of Kurban Bairam will fall this year on about Dec. 10th, 12th, and 13th. That it will be a cholera-infected Haj can scarcely be doubted. Already many infected shiploads of pilgrims have been interned in the lazarets of Sinope (on the Black Sea), of Clazomene (near Smyrna), and Beirût, and without trespassing too much on your space it will be impossible to give the details of all these occurrences. The capacity of all these lazarets has been strained to the utmost, and in order to relieve them it was recently agreed between the Constantinople and Alexandria boards of health that pilgrims' ships from the north, going to the Hedjaz, should do their quarantine in the Egyptian lazaret of El Tor. Quite recently cholera has appeared in Smyrna—whether by spread from the Clazomene lazaret or not is not known. Some 13 indigenous cases have already occurred.

Cholera in Muscat.

The following are the latest returns from Muscat :—

Week ending	Oct. 29th	...	13 cases,	12	deaths.
,, ,,	Nov. 5th	...	—	8	,,
,, ,,	,, 12th	...	—	22	,,
,, ,,	,, 19th	...	—	3	,,

Cholera in Tripoli (Africa).

The following returns have been received from Tripoli (Barbary) since the beginning of the epidemic there on Oct. 3rd :—

Between	Oct.	3rd	and	Oct.	16th	...	12 cases,	9	deaths.
,,	,,	18th	,,	,,	23rd	...	28 ,,	22	,,
,,	,,	24th	,,	,,	29th	...	59 ,,	36	,,
,,	,,	30th	,,	Nov.	2nd	...	58 ,,	48	,,
,,	Nov.	6th	,,	,,	9th	...	50 ,,	31	,,
,,	,,	10th	,,	,,	14th	...	46 ,,	52	,,

It will be noted that these returns are for unequal intervals, and that the figures for some days are lacking. With these reservations the totals amount to 253 cases and 198 deaths. Consular reports from Tripoli give rather different figures; they state that down to Nov. 11th there had been 271 cases and 170 deaths, and add that, with the exception of 1 Maltese, 3 Arabs, and 2 or 3 foreigners, all the cases had occurred in the Jewish community.

Cholera in Tunisia.

Information respecting the cholera outbreak in the island of Jerba, off the coast of Tunisia, has been irregularly received, as shown by the following figures :—

On Oct. 25th							7 cases,	6	deaths.
Between	Oct.	30th	and	Nov.	2nd	...	55 ,,	42	,,
,,	Nov.	6th	,,	,,	9th	...	50 ,,	31	,,
,,	,,	10th	,,	,,	14th	...	32 ,,	36	,,
,,	,,	15th	,,	,,	21st	...	34 ,,	34	,,

Constantinople, Nov. 24th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Dec. 8th, Mr. BUTLIN, the President, being in the chair.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship, stating that 117 candidates were admitted to examination and of these 39 were approved and 78 rejected.

A report was read from the Court of Examiners concerning candidates found qualified for Diploma of Fellow. 67 candidates had presented themselves, and of these 26 acquitted themselves satisfactorily, including two candidates who had not yet attained the legal age of 25 years. It was resolved to issue Diplomas of Fellowship to the remaining 24 candidates. It was resolved to issue Licences in Dental Surgery to 42 candidates found qualified.

A report was received from the Committee on the Annual Report of the Council, and it was resolved, in accordance with the recommendation of the committee, to reply to the proposer and seconder of the resolution advocating the granting to Members representation on the Council, carried at the annual meeting, to the following effect :—

As the matter referred to in the resolution was fully considered by the Council during the present year they are not prepared to re-open the discussion.

The PRESIDENT reported that a vacancy had occurred on the Court of Examiners, and he stated that it would be filled at the meeting of the Council in January. Any Fellow of the College wishing to become a candidate for the office must make application in writing to the Secretary on or before Jan. 4th.

A letter was read from the Assistant Secretary of the Marine Department of the Board of Trade stating that the Board proposes to revise the scales of medicines and medical stores issued by them for merchant ships, and to entrust the revision to a committee consisting, as on the occasion of the last revision in 1888, of members of its medical staff and representatives of the Royal College of Surgeons, Royal College of Physicians, and Pharmaceutical Society of Great Britain, with the addition this time of a representative of the shipping interests concerned; and asking the Council to nominate a representative of the College to act on the committee. Mr. C. T. Dent was nominated to represent the College on the committee.

A letter was read from Sir Henry Morris, Bart., reporting the proceedings of the General Medical Council at its recent session. It was resolved that the best thanks of the Council should be given to Sir Henry Morris for his services as the representative of the College.

A letter was read from the Right Hon. the Lord Mayor announcing the opening of the Mansion House Fund for providing a memorial of King Edward in London, and asking the President to bring the appeal to the notice of Members of the College living in London.

The PRESIDENT reported the delivery of the Bradshaw lecture on Cancer on Dec. 7th by Sir A. Pearce Gould, K.C.V.O., 126 visitors, including Prince Alexander of Teck, being present. The best thanks of the Council were given to Sir A. Pearce Gould for his lecture and he was requested to publish it.

The Sir Gilbert Blane Medals were awarded to Fleet-Surgeon George Trevor Collingwood, M.V.O., H.M.S. *Racer*, 1909; and to Fleet-Surgeon Arthur Reginald Bankart, M.V.O., K.H.P., H.M. Yacht *Victoria and Albert*, 1909. These medals were founded by Sir Gilbert Blane, Bart., F.R.C.S., a distinguished physician best known for the sanitary reforms which he effected in the navy, and the success of the measures which he introduced for scurvy. Two gold medals are conferred once in every two years on two medical officers of the Royal Navy "who in the time required shall have delivered to the proper office journals evincing the most distinguished proofs of skill, diligence, humanity, and learning in the exercise of their professional duties." The journals are submitted for adjudication to the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, and the Director-General of the Medical Department of the Royal Navy.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7869 births and 5445 deaths were registered during the week ending Dec. 10th. The annual rate of mortality in these towns, which had steadily increased in the six preceding weeks from 13·0 to 18·1 per 1000, declined to 16·8 in the week under notice. During the first ten weeks of the current quarter the death-rate in these towns averaged 14·8 per 1000. In London during the same period the death-rate, calculated on a probable over-estimate of its population, was equal to 15·5 per 1000. The annual death-rates last week in the 77 towns ranged from 6·4 in Wallasey, 7·4 in Barrow-in-Furness, 8·6 in King's Norton, and 9·4 in Leyton, to 21·7 in Brighton, 22·7 in Wigan, 24·0 in Tynemouth, and 24·5 in Preston. The 5445 deaths from all causes in the 77 towns last week showed a decline of 421 from the increasing numbers in recent weeks, and included 332 which were referred to the principal epidemic diseases, against 420 and 416 in the two preceding weeks; of these 332 deaths, 143 resulted from measles, 62 from whooping-cough, 39 from diarrhœa, 36 from diphtheria, 30 from scarlet fever, 21 from enteric fever, and 1 from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week fell to 1·0 per 1000 from 1·3 in each of the two previous weeks. No death from any of these epidemic diseases was registered last week

in Willesden, Sunderland, East Ham, Walthamstow, Leyton, Halifax, or in 14 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·3 in Portsmouth, 3·5 in Grimsby, 3·7 in Tynemouth, 3·9 in Rotherham, and 4·0 in Brighton. The fatal cases of measles in the 77 towns, which had steadily increased in the five preceding weeks from 101 to 231, declined last week to 143; the highest annual rates from this disease last week were 1·9 in Portsmouth, 2·1 in Grimsby, 2·4 in Brighton, and 3·1 in Rotherham. The 62 deaths from whooping-cough showed, however, an increase upon recent weekly numbers, and caused the highest rate in Reading. The 39 deaths attributed to diarrhœa were fewer than in any week since last winter. The 36 deaths referred to diphtheria showed a further decline from recent weekly numbers, and included 13 in London and its suburban districts, and 2 each in Portsmouth, Rochdale, Leeds, and Cardiff. The 30 fatal cases of scarlet fever exceeded the number in the previous week by 5; 3 occurred in Manchester and 2 each in West Ham, Birmingham, Liverpool, Bolton, and Sheffield. The deaths referred to enteric fever, which had been 25 and 24 in the two previous weeks, declined to 21 last week, and included 2 in Portsmouth, 2 in Burnley, 2 in Stockton-on-Tees, and 4 in Wigan, which were equal to an annual rate of 2·3 per 1000. The fatal case of small-pox was registered in St. Helens. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had declined in the four preceding weeks from 1882 to 1746, had further fallen to 1719 on Saturday last; 169 new cases of this disease were admitted to these hospitals during last week, against 180, 153, and 170 in the three preceding weeks. The 1703 deaths from all causes in London last week included 506 which were referred to pneumonia and other diseases of the respiratory system, against numbers increasing steadily from 246 to 669 in the five preceding weeks; they exceeded, however, by 140 the corrected average number in the corresponding week of the five years 1905–09. The causes of 49, or 0·9 per cent., of the deaths registered during last week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified last week in Leeds, Bristol, Nottingham, Leicester, Salford, Oldham, and in 47 other smaller towns; the 49 uncertified causes of death in the 77 towns last week included 9 in Birmingham, 7 in Liverpool, and 3 each in Stoke-on-Trent, Bootle, and Bury.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 838 births and 622 deaths were registered during the week ending Dec. 10th. The annual rate of mortality in these towns, which had steadily increased in the four preceding weeks from 13·3 to 17·5 per 1000, declined to 17·2 in the week under notice. During the first ten weeks of the current quarter the death-rate in these eight towns averaged 14·7 per 1000, and was slightly below the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 14·0 and 16·0 in Aberdeen and Glasgow, to 19·0 in Paisley and 23·0 in Dundee. The 622 deaths from all causes in the eight towns last week showed a decline of 11 from the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against 61, 55, and 47 in the three preceding weeks; of these 40 deaths, 13 resulted from diphtheria, 9 from diarrhœa, 8 from whooping-cough, 4 from scarlet fever, 4 from "fever," and 2 from measles, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·1 per 1000, and exceeded by 0·1 the rate from the same diseases in the 77 English towns. The deaths referred to diphtheria in the eight Scotch towns, which had been 14 and 11 in the two preceding weeks, rose again to 13 last week, of which 7 occurred in Glasgow, and 3 both in Edinburgh and in Dundee. The 9 deaths attributed to diarrhœa showed a marked decline from the numbers in recent weeks, and included 2 each in Glasgow, Dundee, and Aberdeen. The fatal cases of whooping-cough, which had been 13, 12, and 10 in the three preceding weeks, further declined to 8 last week, of which 5 were returned in Leith and 3 in Glasgow. The 4 deaths from scarlet fever were fewer than in any recent week; 2 occurred in Dundee and 1 both in Glasgow and in Edinburgh. Of the 4 deaths referred to "fever" 3 were returned in Glasgow and 1 in Leith; 2 were certified as enteric fever, and 2 as cerebro-spinal meningitis, both of which occurred in Glasgow. The deaths referred to diseases of the respiratory system in the eight towns, which had increased from 65 to 157 in the four preceding weeks, declined to 151 last week, and were 123 below the number in the corresponding week of last year. The causes of 26, or 4·2 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 533 births and 432 deaths were registered during the week ending Dec. 10th. The mean annual rate of mortality in these towns, which had been equal to 19·1 and 18·1 per 1000 in the two preceding weeks, rose to 19·6 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these Irish towns averaged 17·3 per 1000; the mean rate during the same period did not exceed 14·8 in the 77 largest English towns and 14·7 in the eight Scotch towns. The annual death-rate during last week was equal to 23·2 in Dublin, 20·1 in Belfast, 13·7 in Cork, 15·6 in Londonderry, 13·7 in Limerick, and 7·8 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 17·0 per 1000. The 432 deaths from all causes in the 22 town districts last week showed an increase of 32 upon the number in the previous week, and included 33 which were referred to the principal epidemic diseases, against 29 and 36 in the two previous weeks; these 33 deaths were equal to an annual rate of 1·5 per 1000; in the 77 English towns the mean rate from the same diseases did not exceed 1·0 per 1000, and in the eight Scotch towns was equal to 1·1. The 36 deaths from these epidemic diseases in the Irish towns last week included 15 from whooping-cough, 5 from diphtheria, 6 from diarrhœa, 5 from measles, and 1 each from scarlet fever and enteric fever, but not one from small-pox. The 15 fatal cases of whooping-cough showed a marked increase upon recent weekly numbers, and included 11 in Dublin and 3 in Londonderry. Of the 6 deaths attributed to diarrhœa (fewer than in any recent week), 4 occurred in Belfast and 2 in Dublin. The 5 fatal cases of measles, of which 3 were returned in Belfast and 2 in Dublin, showed a decline of 9 from the number in the previous week. The 5 deaths from diphtheria, of which 4 occurred in Belfast, corresponded with the number in the previous week. The death from enteric fever was returned in Dublin, and that from scarlet fever in Belfast. The deaths in the 22 towns last week included 116 which were referred to pneumonia and other diseases of the respiratory system, against 80, 100, and 108 in the three preceding weeks. The causes of 18, or 4·2 per cent., of the deaths registered in the Irish towns last week were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·9 per cent., and in the eight Scotch towns it was equal to 4·2 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Edward John Morley has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated Dec. 8th, 1910).

In accordance with the provisions of Order in Council of April 1st, 1881, Deputy Inspector-General of Hospitals and Fleets Joseph Crowley has been placed on the Retired List, at his own request, with permission to assume the rank of Inspector-General of Hospitals and Fleets (dated Dec. 7th, 1910).

The following appointments are notified:—Fleet-Surgeon: H. Spicer to the *Bristol*, on commissioning. Staff-Surgeons: J. C. Rowan to the *Albemarle*, on recommissioning; S. Croneen to the *Mars*, and L. E. Dartnell to the *Victorious*, temporary. Surgeon: C. H. L. Petch to the *Victory*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Captain Edward Gibbon is seconded for service with the Egyptian Army (dated Nov. 13th, 1910.)

Colonel R. Porter has taken over duty as Principal Medical Officer at Malta. Colonel T. J. R. Lucas, principal medical officer of the First (Peshawar) Division, has been transferred from Cherat to Peshawar. Lieutenant-Colonel L. T. M. Nash has been selected to command the station hospital at Karachi in succession to Lieutenant-Colonel R. I. R. Macleod, appointed to command the station hospital at Aden. Lieutenant-Colonel G. F. Gubbin, on arrival home from Colaba, has been posted to the Irish Command. Lieutenant-Colonel A. E. Tate, from Ambala, has taken up duty at Kasauli. Lieutenant-Colonel W. E. Berryman has arrived home from India, tour-expired. An exchange on the foreign service roster has been approved by the War Office between Lieutenant-Colonel C. W. Johnson serving at Gibraltar, and Lieutenant-Colonel S. G. Allen serving in the London District. Lieutenant-Colonel G. Cree has arrived home, tour-expired, from Madras. Lieutenant-Colonel R. R. H. Moore, from Bulford Camp, has been appointed Administrative Medical Officer at Belfast, vice Lieutenant-Colonel E. J. E Risk. Major C. W. H. Whitestone has been transferred from Cherat to Peshawar. Major H. A. L. Howell, from Gibraltar, has taken up duty as Medical Officer in charge of the Royal Army Clothing Factory at Pimlico. Major J. E. Carter, from Landguard Fort, has joined at Chatham. Major A. F. Tyrrell has joined for duty at Fermoy from Kilworth Camp. Major A. O. B. Wroughton has been transferred from the Eastern Command to the Southern Command and appointed Specialist in Dermatology and Venereal Diseases at the Military Hospital, Hilsea. Major H. P. W. Barrow, on termination of his appointment as Adjutant of No. 3 (West Lancashire Division) District R.A.M.C. Territorial Force School of Instruction, has embarked for a tour of service in Jamaica. Captain W. R. Galwey has been appointed Staff Surgeon at Lahore Cantonment. Captain J. P. Lynch, Captain A. Dawson, Captain E. W. Powell, and Captain A. D. O'Carrol have arrived home from India. Captain J. M. Cuthbert has been appointed Specialist in Pathology at Edinburgh. Captain E. W. Powell, from Belgaum, on arrival at Aden, has been placed in charge of the Brigade Laboratory. The following officers (Captains) have joined at the Royal Army Medical College for a course of instruction for promotion to the rank of Major: H. T. Stack, B. G. Patch, A. C. H. Gray, T. S. Dudding, R. H. MacNicol, H. H. J. Fawcett, S. L. Pallant, C. R. Sylvester-Bradley, S. E. Lewis, P. J. Hanafin, J. D. Richmond, E. M. Glanvill, W. MacD. MacDowall, T. J. Wright, F. J. Turner, E C. Whitehead, and R. B. Hole. Captain D. Ahein has been transferred from Cork to Limerick. Captain G. A. Kempthorne, from Amritsar, has joined for duty at Dalhousie. Captain A. F. Carlyon, on termination of his leave from West Africa, has been posted to Devonport. Lieutenant T. W. Stallybrass has joined at the Royal Victoria Hospital, Netley, from Hamilton Camp. Lieutenant A. T. J. McCreery, from West Down North, has been posted to Birmingham. Lieutenant B. A. Odlum, from Tidworth Park, has embarked for a tour of service in South Africa.

INDIAN MEDICAL SERVICE.

Colonel G. W. P. Dennys has been appointed Principal Medical Officer of the Aden Brigade in succession to Colonel W. A. Quayle, transferred as Principal Medical Officer of the Abbottabad and Sialkot Brigades. Lieutenant-Colonel H. B. Melville has been appointed to officiate as Civil Surgeon of Simla West during the absence on leave of Lieutenant-Colonel F. O'Kinealy. Lieutenant-Colonel E. Jennings, Superintendent of the Central Prison at Fategarh, has been granted one month's privilege leave. Lieutenant-Colonel W. H. B. Robinson, Residency Surgeon at Jaipur, has been appointed by the Foreign Department of the Government of India to be Residency Surgeon in Rajputana, in succession to Lieutenant-Colonel H. N. V. Harington, on his retirement. Major A. W. T. Buist has been appointed Civil Surgeon at Ambala. Major J. C. Holdich-Leicester has been granted two years' combined leave home from India. Major A. Leventon has been appointed Civil Surgeon at Darrang. The services of Captain A. E. Grisewood have been placed at the disposal of the Punjab Government for plague duty. Captain H. Watts, district plague medical officer at Hoshiarpur, has been detailed for a course of instruction in clinical bacteriology and technique at the Central Research Institute, Kasauli. The services of Captain H. Ross have been temporarily placed at the disposal of the Government of the United Provinces. Captain R. Kelsall has been appointed to officiate as Resident Medical Officer of the Rangoon General Hospital, vice Captain H. A. Williams, D.S.O., appointed Officiating Superintendent of the same institution. Captain H. C. Buckley has had his leave extended.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Henry R. Borcherds is confirmed in his rank.

The undermentioned lieutenants are seconded for service with the Medical Unit of the Edinburgh University Contingent, Officers Training Corps (dated Oct. 1st, 1910):—William Darling and John M. Darling.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Home Counties Field Ambulance, Royal Army Medical Corps: Captain David L. Hamilton to be Major (dated Dec. 14th, 1910).

4th Southern General Hospital, Royal Army Medical Corps: Captain Arthur E. Carver resigns his commission (dated Dec. 14th, 1910).

5th Southern General Hospital, Royal Army Medical Corps: Captain John Kyffin, from the List of Officers attached to Units other than Medical Units, to be Major (dated Sept. 28th, 1910).

3rd East Anglian Field Ambulance, Royal Army Medical Corps: Walter Rowland Southall Roberts to be Lieutenant (to be supernumerary) (dated Nov. 1st, 1910).

3rd Northumbrian Field Ambulance, Royal Army Medical Corps: Lieutenant Abram C. Barker resigns his commission (dated Dec. 10th, 1910).

2nd West Riding Field Ambulance, Royal Army Medical Corps: Quartermaster and Honorary Lieutenant James Boswell is granted the honorary rank of Captain (dated Nov. 11th, 1910).

Attached to Units other than Medical Units.—Captain John W. T. Walker resigns his commission (dated Dec. 10th, 1910).—Lieutenant Francis W. Squair to be Captain (dated Nov. 17th, 1910).

For attachment to Units other than Medical Units.—George Cordy Jeaffreson to be Lieutenant (dated Nov. 7th, 1910).

Officers Training Corps.

Edinburgh University Contingent, Senior Division, Officers Training Corps: Lieutenant William Darling (serving with the medical unit), to be granted the local rank of Captain, with the pay and allowances of that rank (dated Oct. 1st, 1910).

THE TERRITORIAL FORCE NURSING SERVICE.

On Nov. 13th the Lady Mayoress presided at the annual meeting of the Grand Committee of the City and County of London Territorial Force Nursing Service, which was held at the Mansion House. The annual report showed that the expenditure had been £33, and that applications for enrolment continued to be numerous.

DEATHS IN THE SERVICES.

Brigade-Surgeon-Lieutenant-Colonel John Mackenzie, A.M.D., at Dover, in his seventy-eighth year. He entered the service in 1858 as assistant surgeon, and reached the rank of brigade-surgeon in 1884. He served throughout the campaign of 1860 in North China (medal) and retired in 1888.

THE HEALTH OF THE ROYAL NAVY.

The annual statistical report of the health of the Navy for the year 1909 shows that, compared with the preceding five years, the health of the service continues to improve, the invaliding and death ratios being lower and the average loss of service for each person less. The report, with which we hope to deal more fully in an early issue of THE LANCET, contains interesting appendices on vision, on colour tests, and on beri-beri.

Captain Howard Ensor, D.S.O., R.A.M.C., has been granted the Royal licence and authority to accept and wear the Imperial Ottoman Order of the Osmanieh, Fourth Class, which has been conferred upon him by the Khedive of Egypt in recognition of valuable services rendered.

Correspondence.

"Audi alteram partem."

CARCINOMA IS A PARASITIC DISEASE.

To the Editor of THE LANCET.

SIR,—Sir Alfred Pearce Gould, in his most interesting and suggestive lecture on cancer, at which I had the satisfaction of presiding at the Royal College of Surgeons of England on Dec. 7th, criticised very courteously the views which were expressed in my Bradshaw lecture five years ago.[1] He quoted my "text" correctly: "That the carcinoma cell is an independent organism, &c.," but he did not correctly quote the arguments I used later in the lecture. For his next paragraph (addressed to me) was as follows: "You shrank from accepting Hauser's suggestion that the protozoal cells of cancer are derived or descended from the living cells of the host, and asserted rather that 'the parasite is introduced into the body from without.'"[2] My actual words are thus quoted and the only place in which I can find them in your report of my lecture is in the following sentence: "I suppose we must then assume that *the parasite is introduced into the body from without*, after the manner of parasites generally; or that it is formed, in some unknown manner, within the body of the host."[3]

After discussing the evidence in favour first of the external, then of the internal, origin of the carcinoma cell, I said: "It must be admitted that these three features of carcinoma, the characters of the cell, the structure of the tumour, and the age-incidence, make it difficult to conceive the idea of a parasite introduced into the body from without. And they do strongly suggest that the parasite is actually formed or developed within the body of the host, and that it is in some manner derived from the elements of the host. Hauser has no doubt that his new race of cells is derived from the elements of the host, and appears to find no difficulty in the hypothesis. I confess to me it is an astounding proposition, for, set forth in plain terms, it is none other than the origin of new species of the lowest forms of animal—of protozoa. The mode of origin which is suggested is so different from that we have been accustomed to accept for the last five-and-twenty years that I scarcely dare to set it down in words. That there will be much discussion and dispute over it I cannot doubt, for I am quite confident that time and research will confirm the view I have expressed to-day of the nature of the carcinoma cell."[4]

In order to be sure of the views I had expressed, I read my lecture through very carefully. There is no doubt that I heartily wished, at the time I delivered it, that the evidence would be in favour of the entrance of the carcinoma cell from without. But I was forced to acknowledge that the evidence was stronger in favour of the formation of the cell within the body. Following the argument to its logical conclusion, I was further forced to admit that, if this were so, it would be necessary to admit that the carcinoma cell is a new creation, and, still further, that it was probable this new creation was derived from the elements of the host. No wonder, in the face of this conclusion, I was astonished at the light manner in which Hauser treated the hypothesis. I am sure the real truth never dawned upon him. Nor do I think that Dr. C. Powell White,[5] who expressed the view "that the cells themselves of cancer act as parasites," really appreciated the significance of his suggestion. For he takes the view of Adami that the cells acquire the "habit of growth." "Once the cells have acquired this habit they behave as independent parasites."[6]

I am very glad that Sir Alfred Pearce Gould has given me the opportunity of again stating my case. It has never been out of my mind for long together during the last five years. I have been watching all the new evidence which has been derived from observation and experiment, and have been collecting certain evidence on my own part with the intention of again advancing and defending the argument of the Bradshaw lecture of 1905. I shall hope to do this in the course of the coming year, either in a couple of lectures or in some other manner.

In the meantime I would say that every discovery of the last five years is in favour of the "text" of my Bradshaw lecture: "That the carcinoma cell is an independent organism, like many a protozoon; that it lives a life which is wholly independent and proper to itself; and that it lives as a parasite in the body of the animal which is affected with carcinoma, deriving its nourishment from this host, and doing nothing to repay the host for the sustenance of which it robs him." The evidence which was at that time a little in favour of the internal as against the external origin of the carcinoma cell has been much strengthened. And I am prepared to apply the theory to cancer of every kind instead of limiting it (as I did five years ago for convenience) to carcinoma.

I am, Sir, yours faithfully,

Dec. 12th, 1910. HENRY T. BUTLIN.

[1] THE LANCET, 1905, vol. ii., 1748.
[2] THE LANCET, 1910, vol. ii., p. 1665.
[3] Loc. cit., p. 1753.
[4] Loc. cit., p. 1753.
[5] When I first formed the opinion that the carcinoma cell is an independent organism and acts as a parasite in the body of the host, I did not know it had ever been previously expressed. Shortly before delivering the Bradshaw lecture I discovered Hauser's paper in Ziegler's Beiträge, 33, S. I., 1903; and, two years ago, Dr. C. Powell White pointed out to me that he had made a similar suggestion in his Erasmus Wilson lectures at the College of Surgeons in 1902. In his "Lectures on the Pathology of Cancer," Manchester, 1908, he concludes the last lecture with these words: "We can say, then, that cancer is not due to a specific parasite or parasites, but, on the other hand, we can say that the cancer cells themselves act as parasites. This latter view will explain all the phenomena of cancer."
[6] THE LANCET, 1902, vol. i., p. 494.

THE BRADSHAW LECTURE ON CANCER.

To the Editor of THE LANCET.

SIR,—In Sir Alfred Pearce Gould's most interesting Bradshaw Lecture on Cancer he notes that primary cancer is not always single. Years ago, in the post-mortem room of Guy's Hospital, several times in the course of ten years or so I came across what seemed to be two independent centres of cancer in the same body. Such cases, however, do not occur often, unless, perhaps, new growths are too hastily assumed to be *secondary* when they are not really so, and I am by no means sure that this may not sometimes be the case. But what I did more commonly find, as others must have done, was the presence of innocent new growths in the same body with malignant ones, multiple lipomata or fibromata more especially. And it has always seemed to me that the two phenomena may need consideration the one with the other when the origin of cancer is in question.

I am, Sir, yours faithfully,

Portland-place, W., Dec. 10th, 1910. JAMES F. GOODHART.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—I would not have trespassed on your valuable space had your reviewer of the "Phases of Evolution and Heredity" not shown a most ludicrous ignorance of the subject criticised. He states on p. 1618 of THE LANCET of Dec. 3rd: "To put it briefly, the 'theory' suggested by himself is that 'the gametes, before combination to form a zygote, do not contain the complete outfit of determinants necessary to form an adult and its progeny'; that changes in the zygote make up the necessary complement; and it is these zygotic changes which produce the results known as 'Mendelian.'"

This definition of what your reviewer terms "Mendelian results" is quite absurd. The union of the necessary gametes whose chromosomes have been reduced to a half by the loss of the polar bodies makes up a zygote with the necessary number of chromosomes, as van Beneden showed in 1883. This is a great fundamental fact in embryology, but has to do with fertilisation, not with Mendelism. The statement that my theory is "that changes in the zygote make up the necessary complement" is probably the best imitation of Lewis Carroll's nonsense that I have read. When the zygote is formed the chromosomes are complete and need no supplement. What the review shows is that your reviewer has not grasped the elements on which fertilisation is based.

My difficulty, however, is to find out from your reviewer's caricature what theory he refers to. I suspect it is the theory of zygotic segregation that has confused him.

The essence of Mendelism is, in my opinion, autonomy of the unit-characters, so that they do not blend in transmission, but reappear unchanged in a certain ratio. The results of

Mendel's experiments were to show that the contrasted unit-characters gave plants with these contrasted characters in the ratio 1:2:1, a frequency result. Mendel's theory—gametic segregation—was that this was a frequency result due to the combination of the pollen grains and egg cells and thus like $(a + b)^2$ we get 1:2:1. For reasons I need not state here I have suggested that the determinants of the unit-characters are segregated according to the law of frequency, and that this happens in the zygote. This was suggested to me by the changes in the free-martin, a sterile bull usually co-twin with a potent bull, both derived from one zygote, where in the zygote the unit-character (epoöphoron and prostatic utricle) is segregated into the sterile animal. The question of gametic combination *versus* zygotic segregation is the most important in Mendelism. Everything depends on it—it is not a "slight criticism of Mendelism"—and that is my main reason for troubling you with this letter.

I am, Sir, yours faithfully,

Edinburgh, Dec. 5th, 1910. D. BERRY HART.

*** The author's complaint is just. The attribution to him in the review of the statement that "changes in the zygote make up the necessary complement, &c.," was an error. It should, of course, have been explicitly stated that the zygotic segregation specially insisted on by the author is subsequent to the union of gametes which makes up this necessary complement. Our reviewer writes regretting the error, adding: "But that it was not due to a misunderstanding or purposive misrepresentation of the author's special theory is clear from the subsequent quotations from pp. 94, 95 of the book. The sentence quoted by the author as the reviewer's 'definition' of Mendelian results was not a definition of anything, but merely a condensed indication of the line of argument employed to lead up to the author's theory of 'zygotic segregation' or division of the zygote into a 'propagative and a somatic part,' which he opposes to the hypothesis of gametic segregation as set forth by Mendel. The reviewer's error, even if it had been made in ignorance, does not touch the main criticism, which is, in effect, that the intrinsic theory of variation, &c., is but a hypothetical amendment, or an attempt at a reconciliation, of certain existing hypotheses rather than a comprehensive handling of the subject as a whole."—ED. L.

THE INTRAVENOUS INJECTION OF SALVARSAN, OR "606."

To the Editor of THE LANCET.

SIR,—Salvarsan, or "606," to give Professor Ehrlich's salt its more popular name, may be given by intramuscular or by intravenous injection. When administered intramuscularly there is for some few days after undoubtedly a very considerable amount of pain, which may be controlled by morphia; but morphia, whatever "606" may turn out to be, is certainly no cure for syphilis, and the patient is better without any further addition from the Pharmacopœia of a poisonous nature, saturated, as he already is, with the spirochæta and the salvarsan. On the other hand, when the injection is made directly into the vein, there is no pain caused beyond the prick of the needle, either at the time of the operation or afterwards.

This point alone is a very definite reason for a preference in favour of the intravenous method, and a reason to which the patient himself would be the first to subscribe. Beyond this, however, I think I can, reasoning by analogy, give good cause to show why it should also have the preference over intramuscular injection on account of its probable greater action and efficiency when introduced intravenously. Now, during the years 1896–1897, when I published a paper on the Technique of the Treatment of Syphilis by Intravenous Injection of Mercury,[1] I had certain primary and secondary cases in private undergoing six-week courses of this treatment three times a year over two years, with, at the time, highly satisfactory results. These cases being in private enabled me, when Wassermann perfected his reaction, to communicate with them and to obtain their blood for the purpose of finding if they were positive or negative to the disease.

Although, from the point of view of statistics, the numbers are not numerous enough to deduce any absolute conclusion, yet the way their bloods have been returned as negative, without exception, is highly suggestive of the efficacy of that treatment by mercury directly into the blood-stream. The reason for this efficacy is, I take it, that the medicament is directly introduced into the very atmosphere of the body, into the blood-stream itself, and so has the same advantages as the spirochæta which has taken the same road to reach the most out-of-the-way cells and tissues, where, taking part in their metabolism, the "war" with the poison is carried on simultaneously and immediately all over the body. Again, owing to the rapid excretion of the mercury when given in this way, the injections being repeated three times a week, the specific poison receives hard and direct blows delivered against it with a very telling frequency.

Now if this reasoning is correct for Hg, how much more important is it to make the blow delivered by salvarsan a "knock-out" one; for here we are aiming at attaining our object of the total destruction of the spirochæta by means of one single injection, and look upon the necessity of repeating the operation as a comparative failure; for, whatever Hg may do, there is a probability that the complicated molecule we name salvarsan or "606" induces the blood to give rise to an antigen, because if we fail with the first dose to annihilate, any second dose must be greater in quantity to enable us to produce the desired result. In conclusion, therefore, if we have in salvarsan a bullet which will kill the enemy, I hope I have given some good reason for showing how we can make that bullet a dum-dum.

I am, Sir, yours faithfully,

Sackville-street, W. JAMES B. BYLES.

THE OWNERSHIP OF PRESCRIPTIONS.

To the Editor of THE LANCET.

SIR,—I am glad to learn from Dr. Lucas Benham's letter, which appears in this week's issue of THE LANCET, that my article on the above subject has excited interest, and has been on the whole approved so far afield, and particularly that Dr. Benham makes it a practice to indicate on the face of every prescription he writes the maximum time for which it should be used. This excellent practice deserves, however, to be supported by better arguments than those which can be deduced from the analogy—in my opinion a false one—of a cheque. There is no parity in the conditions. A cheque is an order addressed to a banker, requiring him to pay a sum of money to a certain person, or to the bearer of the cheque, out of funds previously deposited with him by the writer of the cheque. A prescription is a formula given by a physician to his patient, who can have it compounded by any competent person he chooses to employ. The banker is an agent of the maker of the cheque; the dispenser is an independent contractor who deals only with the holder of the prescription. These are the conditions generally obtaining in this country; they may perhaps be modified in South Australia.

THE RESULTS OF BRONCHIAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—I have just read Dr. Newton Pitt's admirable Bradshaw Lecture with great interest, for it has taught me something that I did not know before, although that something has been under my observation for many years and I have missed it. I refer to the fact that a partial compression of a bronchus is capable of producing an over-distended lung. On finishing Dr. Pitt's lecture I immediately looked up my skiagrams of aneurysm, and found that three out of seven show the condition distinctly. I have not yet had time to go through my hospital cases, but intend doing so on the first opportunity. As Dr. Pitt has kindly mentioned my name in connexion with two of the published skiagrams I feel that a word about them will not be out of place. I remember the cases well, as they occurred in Victoria Park Hospital. The skiagram shown in Fig. 7 was actually mistaken for a pneumothorax, but that was as long ago as 1902; since

then we have become more critical. I am quite sure now that the case was one of overdistended lung and not a pneumothorax, for the following simple reason that I have never seen a skiagram of a pneumothorax that did not show a shadow of the collapsed lung. The shadow of the collapsed lung of course varies a good deal, but it is always there. It may show a very considerable shadow, as in Fig. 8 of Dr. Pitt's lecture, due, no doubt, to the tuberculous infiltration preventing complete collapse. In other cases the shadow of the collapsed lung can be seen running beside the spinal shadow, but it is always there. I hope to place these cases on record shortly.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 10th, 1910. HUGH WALSHAM.

TREATMENT OF ULCERS OF THE LEG BY A PASTE.

To the Editor of THE LANCET.

SIR,—Your annotation in THE LANCET of Dec. 10th, p. 1716, implies that Dr. B. A. Thomas has discovered a new treatment for varicose ulcers. Twenty years ago when an outpatient dresser at St. Thomas's Hospital I spent most of my time dressing varicose ulcers more or less successfully with what we as students called "Unna's"—the composition of this paste being glycerine, gelatin, and zinc oxide—applied warm on carbolic gauze. I still use this preparation, and it is quite the best provided the dressing is applied from the arch of the foot to the tubercle of the tibia.

I am, Sir, yours faithfully,

Bromley, Kent, Dec. 10th, 1910. C. W. GRANT-WILSON.

INVALIDITY INSURANCE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Dec. 10th Mr. W. A. Robertson, actuary, Century Insurance Company, raises the question of invalidity insurance in a most interesting manner. In doing so he states that whilst mortality is improving invalidity is increasing, and he bases his argument on the grounds of the available statistics of his company during the past 25 years with reference to sickness insurance. Quite recently, elsewhere, I had the opportunity of raising and discussing this very question with Mr. Robertson, and now that it has appeared in the columns of THE LANCET I would like to add a few remarks. Remembering that I am engaged as medical examiner to insurance companies in London, I cannot accept his deductions as to an increased invalidity as they are based upon selected statistics which are always open to error, and for the same reason "returns" from benefit societies are not a true index as to increase of invalidity. For my purpose it is unnecessary to refer to the conditions under which sickness policies are issued to the public, and the members of the medical profession are well aware of the amount of abuse that arises in connexion with benefit societies. I need only cite the cases where men in addition to having a sickness policy are also members of two or three benefit societies to show how erroneous it would be to draw any conclusion as to increased invalidity from any statistics relating to such persons. I am sure that all students of public health and preventive medicine will require stronger proofs on the question of increased invalidity than those forthcoming from insurance companies and benefit societies. I take it as a significant sign of the times to find the insurance companies appreciating and acknowledging the achievements of public health and preventive medicine, and in my opinion it will not be long before all large commercial undertakings will find it to their advantage to have the assistance of medical men holding the D.P.H. I need hardly say that the statistics published and compiled by the life offices have no relation to those relating to sickness insurance, and if they did not relate to selected lives could be taken as a true index to the mortality of the entire community.

I am, Sir, yours faithfully,

Cannon-street, E.C., Dec. 12th, 1910. JOHN J. SCANLAN.

To the Editor of THE LANCET.

SIR,—Mr. W. A. Robertson's letter on Invalidity Insurance in your last issue contains some interesting statistics of the relative amount of sick benefit paid to members of different ages under a system of sickness insurance during the past 25 years. The statistics referred to in the letter do not, however, give any support to the assertion that "it is an indisputable fact that sickness is actually on the increase." The returns of the Century Insurance Company, to which Mr. Robertson, as actuary, has access, may quite probably show an increasing rate of claims for sick benefit among the members in recent years, although his letter does not contain any proof of such increase. Moreover, if the existence of such increase be assumed, it could not be accepted as proof of any real increase of sickness, but only as proof that under this system of insurance, as Mr. Robertson admits, "people now lie up where previously they would have continued to work." A satisfactory national system of sickness insurance has long been a desideratum with those interested in sanitary progress, but the differentiation of what constitutes definite sickness presents one of the difficulties that still stand in the way of its realisation. Mr. Robertson remarks on the incongruity of his assumed fact that "while mortality is declining invalidity is increasing," and it would indeed be surprising if a real increase of sickness could be proved to exist coincidently with the recent steady decrease in the national death-rate. Insurance against sickness, and the resulting benefit during invalidity, is undoubtedly beneficial to public health, and very probably assists in reducing the death-rate, but it is obviously impossible to accept increase of payments by an insurance company for sick benefit as conclusive proof of a real increase of sickness, even among its members. Similarly, experience of the results of the Workmen's Compensation Act suggests a marked increase of accidents and injuries to workmen, but should not be accepted as any proof of actual increase in the proportion of occurring accidents and injuries. If Mr. Robertson has access to statistics showing a marked increase in the ratio of sick benefit paid to the members of his company in recent years, they would be interesting, but they must not be assumed to prove actual increase in the ratio of national sickness.

I am, Sir, yours faithfully,

Surbiton, Dec. 12th, 1910. NOEL A. HUMPHREYS.

THE MOTOR FUNCTIONS OF THE STOMACH.

To the Editor of THE LANCET.

SIR,—I have been interested in reading the criticisms, by Dr. Arthur F. Hertz, of my recent small article on the Motor Functions of the Stomach. One ought to welcome criticism, but that of Dr. Hertz is based very largely on his own personal observations and interpretations of these, which one has yet to learn have been so widely accepted as he appears to imagine. His quotation of authorities (and manner of speech) would lead one to think that all of them are in agreement with him, and that all phenomena in connexion with this subject are simple, straightforward, easy to demonstrate, and further, that "Mr. Gray's" is the only dissentient voice, which is, however, negligible in that "Mr. Gray" is hopelessly behind the times! One knows that the quoted authorities do not agree on many points with Dr. Hertz, as I shall show in the case of some of them.

I should like to criticise his letter in return, paragraph by paragraph, because he has charged me with "numerous inaccuracies" and "mistakes"!

In the first paragraph he states that I ascribe, in papers published in 1908, "the discovery of secretin to Wertheimer, without even mentioning the names of Bayliss and Starling." The actual words in my first paper (Feb. 22nd, 1908) are "as Wertheimer and others have shown, acid in the duodenum excites the production of secretin." In the same paragraph of my paper an extensive quotation, duly ascribed to Starling, appears.

With regard to the second paragraph, *my* first observations on the human stomach with the X rays were made in the *vertical as well as* the horizontal position. If Dr. Hertz had taken the trouble to read *accurately* my second paper (July 25th, 1908) he would have seen this and been possibly prevented from hinting that I had been less thorough in my methods than he, seeing that his patients up till then

had been examined only in the horizontal posture. This is, however, a small matter! In spite of previously having read Dr. Hertz's paper, which he kindly sent to me, in which he gives "reasons in detail" for being convinced that there is no such thing as a "middle sphincter," I have yet to be convinced that there is not.

I shall next consider paragraph 5, in which Dr. Hertz expresses a wish to know the names of "recent radiographers and others" who "assert that the pylorus during gastric digestion descends naturally below and to the left of the umbilicus." In consideration of the possibility that Dr. Hertz has placed the names of his "recognised authorities" on the subject in what he estimates as order of merit, I am quite pleased to take the combined statements of the first two. Barclay (Proceedings of the Royal Society of Medicine, Electro-Therapeutical Section, February, 1909) says: "The whole organ is placed to the left and seldom transgresses the middle line except when it is full of food, and then only by half an inch or so. Its lower border is usually a little below the umbilicus in the upright position," and Pfahler (quoted by Dr. Hertz in his paper of July, 1910), and also Holzknecht, state that in their "normal" stomach the pylorus is the lowest point! It is but just to remark that Barclay says that it "was very exceptional to find the pylorus as the lowest point." If the two premier authorities of Dr. Hertz's list disagree in this way, whom are we to believe, especially as both disagree with Dr. Hertz?

Reverting to paragraphs 3 and 4, Dr. Hertz has evidently an idea differing from mine as to what is to be taken as the dividing line between the cardiac and pyloric portions of the stomach. I may say that my ideas have been based on the description given by the late Professor Cunningham, which is practically repeated by Dr. Hertz in his paper which was published so late as July, 1910. I stated in my papers that peristalsis occurs in the distal part of the cardiac portion, and this statement has been made by others—for example, some of Dr. Hertz's "recognised authorities." I shall be obliged if Dr. Hertz will quote any "recognised authority" other than himself to justify his remark that it is "now universally acknowledged (except by Mr. Gray) that there is no peristalsis in the cardiac end." It is pleasant to think that Dr. Hertz admits and figures in his paper of July, 1910, that a tonic contraction, sufficient to keep the walls of the empty stomach in close apposition, affects the whole of the stomach beyond the fundus, which is after all but a small part of the cardiac end. Why should peristalsis affect only a small part of this tonically contracted tube? I submit that my observations are supported by the anatomical findings of such an indubitably "recognised authority" as the late Professor Cunningham. So far as his other statements in these two paragraphs are concerned, I can only say that Dr. Hertz appears to have unbounded confidence in the infallibility of his own observations. If they are correct of course I am wrong.

In paragraph 6 Dr. Hertz asks, "Who are the 'recent radiographers' who say that 'carbohydrate food' begins to pass through the pylorus (displaced as described) in 15 to 20 minutes, and proteid in 30 to 45 minutes?" Again I seek to take an average, but quote, for accuracy, Dr. Hertz's first-mentioned "recognised authority"—viz., Barclay—he who says that "the whole organ is placed to the left," and therefore the pylorus must also be. Barclay says that carbohydrate food commences to pass "out of the stomach" in from 5 to 40 minutes. That is to say, he observes the passage of food through a sphincter which is evidently situated to the *left* of the midline. Dr. Hertz evidently agrees that the pylorus occupies its usually accepted position to the *right* of the middle line. Does it not appear reasonable to suggest that Barclay mistakes "the middle sphincter for the pylorus," and, further, that these are the times when food begins to pass through the middle sphincter? The statements made by Dr. Hertz in this paragraph, "that food, whatever its nature, begins to pass through the pylorus at once," is news! This may occur in infants, but all his "recognised authorities" differ from him, as well as do the previously recorded statements of Dr. Hertz himself. One supposes, of course, that Dr. Hertz speaks of ordinary *food*, not ordinary water or even albumin water. Are we to disregard all the work of physiologists, physicians, and even some surgeons with regard to the check action of the pylorus which has hitherto been regarded, under normal conditions, to require at least a little free hydrochloric acid before its sphincter action is unloosened?

In paragraph 7 Dr. Hertz again refers to Dr. Barclay (who places the pylorus in a wrong position) as confirming his own observations in connexion with duodenal ulcer. "The picture of a normal stomach exhibiting excessive peristalsis and passing the food on very rapidly is always suggestive of trouble in or about the duodenum." It is "universally acknowledged" (possibly there are exceptions) that hyperchlorhydria is a concomitant of ulcer, whether gastric or duodenal. Dr. Hertz agrees (in his paper of July, 1910) that hydrochloric acid is possibly the chief chemical stimulant of peristalsis, and there is little wonder that peristalsis should be excessive if the hydrochloric acid is excessive, but it has also been agreed that hydrochloric acid in marked excess stimulates pyloric spasm. I repeat, therefore, my remark that the interpretations of radiographers require criticism. One cannot allow that Dr. Barclay's observations confirm Dr. Hertz's when they differ on such an important point as the position of the pylorus.

With regard to Dr. Hertz's further remark, that he cannot understand how the period of relief of hunger pain is evidence in favour of a middle sphincter, I reply that it is to my mind just as much so as the relief of hunger pain of duodenal ulcer is evidence of pylorospasm. Destructive criticism, especially in the absence of confirmation, is easy—let Dr. Hertz give a reasonable explanation!

With regard to Dr. Hertz's remarks in paragraph 8, I may say that I have repeatedly seen intestinal segmentation, both as represented by the skiagraphic picture of the intestinal contents and also by direct vision of exposed human intestine. If Professor Cunningham's representation of the muscular coat of the stomach is correct I maintain that *modified* segmentation *is* possible in the part along the lesser curvature of the cardiac portion, and my observations in certain cases have led me to compare the passage of food masses along this part to the passage of segmented masses along the intestine. These may possibly be the same as the "blobs" referred to by Dr. Hertz and Dr. Barclay.

The literature on this subject is beset with so many contradictory statements that confirmation or criticism is urgently required. I shall be extremely glad if I stimulate others to take up the matter so that the truth may be arrived at as nearly as possible. As I indicated in my paper of Dec. 3rd, I shall not at all object to accept new views, but at present the ones I hold explain most easily and rationally clinical symptoms both before and after the operation of gastro-enterostomy.

I am, Sir, yours faithfully,

Aberdeen, Dec. 10th, 1910. H. M. W. GRAY.

THE USE OF "606."

To the Editor of THE LANCET.

SIR,—In view of the fact that the Ehrlich-Hata preparation, or "606," is now being put on the market, it is well to consider how far this preparation has fulfilled its expectations. That it has a rapid healing effect in certain cases appears definite, but the earlier reports of its wonderful effects were premature and probably exaggerated. The claim that it could effect an abortive cure of syphilis, or "sterilisatio magna," has not been substantiated. Professor Neisser, who was at first an ardent supporter of the new treatment, has since modified his opinion and recommends a combination with mercury and iodides. Professor Gaucher is anything but enthusiastic, and considers "606" only indicated in cases which resist mercurial treatment, but that such cases are rare. As regards the toxic effects of the drug, these appear to be less than those of atoxyl and arsacetin, but several deaths have occurred after injections of "606," some of which, if not entirely due to the drug, were probably hastened by it. Under these circumstances, it appears questionable whether we are justified in submitting patients, in the great majority of cases of syphilis, to treatment by "606," and perhaps losing valuable time by neglecting mercury and iodides.

I am, Sir, yours faithfully,

C. F. MARSHALL.

St. John's Wood Park, N.W., Dec. 10th, 1910.

TORONTO FREE HOSPITAL FOR CONSUMPTIVES AND THE KING EDWARD SANATORIUM FOR CONSUMPTIVES.

(FROM A SPECIAL CORRESPONDENT.)

THESE institutions, which are under the same control, are situated at a distance of four or five miles from Toronto, and the Free Hospital for Consumptives at the time of its establishment in the year 1904 was a somewhat new departure in therapeutics. The Muskoka sanatoriums for tuberculous patients, concerning which I wrote some few weeks ago,[1] were established for the treatment of those suffering from tuberculosis residing in any part of the province of Ontario, whereas the Toronto institutions are only for those afflicted with the disease who are residents of Toronto itself. Moreover, the especially distinguishing feature of the Toronto Free Hospital for Consumptives is that advanced, even far advanced, cases of tuberculosis are received—in fact, those cases that other hospitals refuse. It is a truism to state that in cities one of the chief causes of the spread of tuberculosis is infection from advanced cases. Persons with limited means are compelled to live in crowded houses and small, ill-ventilated rooms, by which the danger of infection is greatly increased. There is no doubt that if advanced cases could be strictly isolated tuberculosis in towns would not be nearly so rife as it is now. The Toronto Free Hospital for Consumption was the first institution established in this country for minimising the danger. By the courtesy of Mr. W. G. Gage, chairman of the board of directors, I was invited to visit the hospital, and accordingly travelled thither by street car. The first portion of the journey took me through a part of the factory district of Toronto, and I was greatly struck by the neat and even picturesque appearance of the factory buildings. These offered a complete contrast to the majority of such buildings on the outskirts of British cities, grimy unpleasant-looking places for the most part. The Toronto factories are housed in clean comfortable buildings, covered by creeping plants and with flowers at the windows. The latter part of the journey is through beautiful rural scenery, and the situation of the institutions themselves could scarcely be bettered. They are placed at a distance of perhaps half a mile from the main road, standing in grounds of 40 acres, on a plateau overlooking the lovely valley of the Humber.

The Free Hospital.

Regarding the buildings which constitute the Free Hospital, it must be understood that they are quite unambitious in design and architecture and seem to fit in with the scenery exactly. Their erection has been an example of making bricks without much straw. The original building was a farmhouse which has been added to as necessity or occasion demanded, and the result is seen in a rambling line of low buildings, mostly of wood. The farmhouse is now used for administrative purposes, and contains the offices of the medical attendants, dispensary, examination room, and rooms for the accommodation of the staff. Dr. W. J. Dobbie, physician-in-chief, was good enough to show me over the institution and to give me all the information asked for. The staff consists of the physician-in-chief and two assistant medical men, a lady superintendent, and about 20 nurses. The accommodation for patients is sufficient for 140, 100 or so being housed in the Free Hospital, while the King Edward Sanatorium will hold 38 patients. At the time of my visit the Free Hospital was practically full. Seventy inmates were able to get about to a greater or less extent, whilst 30 were entirely confined to their beds. The equipment of the hospital is adequate and thorough, and the latest scientific appliances are provided. The women are placed in the front of the building, and as far as is possible the fresh-air treatment is adhered to. Along the front of the hospital are wide verandah rooms, the glass shutters of which may be raised or lowered as the medical attendant may think fit. Fig. 1 represents women taking the fresh-air treatment in winter. The far advanced cases are confined to their beds in the upper storey, the majority of these having separate rooms. Men patients who have the disease in a less advanced stage live in shacks similar to those described in the article on the Muskoka Sanatoriums, these shacks being placed at the back of the main building at right angles to it at one side, the other side being occupied by nine old railway street cars; thus the main building, shacks, and street cars enclose a good-sized space which is utilised for garden purposes. Consequently there is no lack of air and light on all sides of the buildings. Each shack contains from six to eight beds with ample lavatory arrangements. The use of the old street cars was suggested both by motives of economy and convenience. They were presented by the Toronto Street Railway Company. Each makes an excellently cosy room and contains a bed, a stove, and some simple articles of furniture. The street cars are greatly in favour with the patients as places of abode, mainly, no doubt, on account of the comparative privacy ensured thereby. Fig. 2 represents the exteriors of the street-car homes. There are 12 children in the Free Hospital at the present time, for whom a schoolroom and teacher are provided. Dr. Dobbie is now having the large verandah at the end of the administration building fitted with glass shutters and equipped in such a manner that it may be used as an open-air schoolroom. It should be mentioned that the patients' beds are not placed close to the wall, for the reason that the floor on all sides of the bed may be the more easily cleaned. The spittoons provided are small flat tin boxes, in which are placed fairly tight-fitting boxes made of stiff moisture-proof paper. At regular intervals the inside boxes are removed and destroyed, thus doing away with the need for disinfecting the spittoons perpetually, while affording the opportunity for easily examining the sputum. The handkerchiefs used are made from soft, cheap cotton material, buttercloth in fact, and are destroyed after use.

The patients who can do light work are encouraged in this course. The ones who are able to be up are expected to make their own beds and to keep tidy their particular parts of the ward. To two men is given the duty of cutting the rolls of buttercloth into handkerchiefs, and to two women is given the duty of folding the serviettes for the table. Another patient burns daily the sputum-boxes. The experiment is being tried of placing the enclosed vegetable garden already referred to under the charge of patients. Indoor amusements are provided both for men and women.

During the past five years the statistics of treatment of *far advanced* cases has been as follows: apparently cured, none; disease arrested, 1; much improved, 42; stationary, 40; failed, 30; died, 282. The figures for the *advanced* cases during the past five years were as follows: apparently cured, 3; disease arrested, 21; much improved, 148; stationary, 60; failed, 20; died, 41.

As said before, the great benefit to the community at large in having advanced cases of tuberculosis carefully isolated is the main *raison d'être* of the hospital, and considered from this point of view its value has doubtless been incalculable. Towards the upkeep of the Free Hospital the city of Toronto subscribes the sum of 70 cents (3*s*.) per capita daily, and the provincial authorities make a further contribution of $3 (12*s*.) per week for each patient.

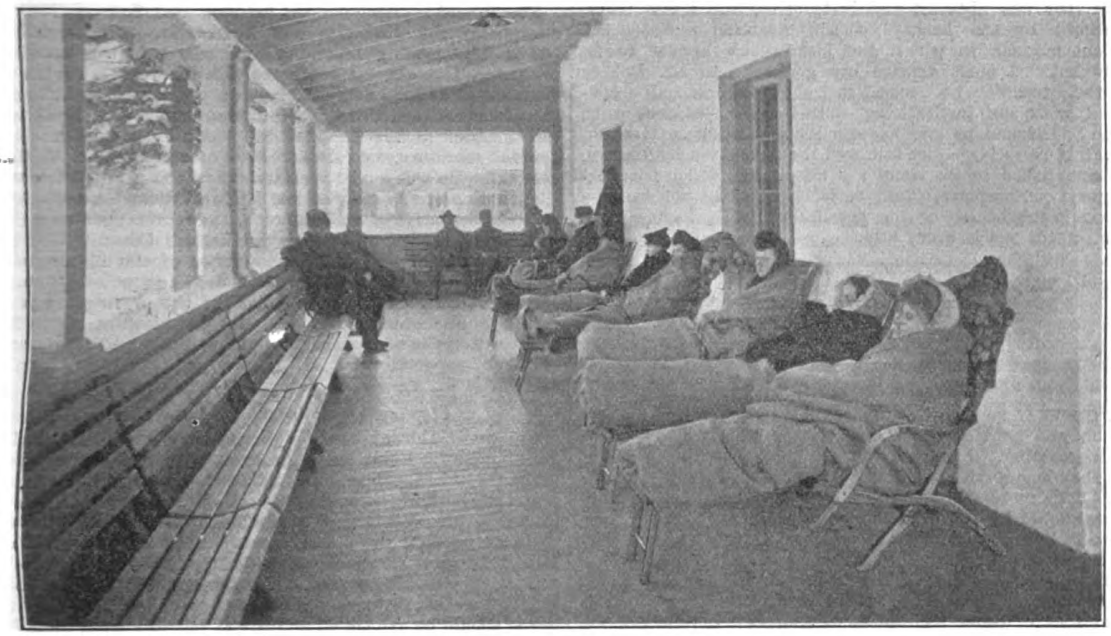
The King Edward Sanatorium.

The King Edward Sanatorium for Consumptives, which was opened to receive patients in September, 1907, is designed to care for tuberculous patients in the incipient and moderately advanced stages. The sanatorium buildings are situated some 300 yards from the Free Hospital buildings. The building which contains the administrative offices and rooms was the gift of the late H. C. Hammond of Toronto. The sanatorium itself, termed the Mulholland Building, was the gift of Robert Mulholland of Toronto. To this building is attached the dining-room building. The three buildings are connected by a covered corridor. The Mulholland Building is particularly handsome, well-built, and spacious; bathrooms are provided on each floor, and a wide verandah extends the whole length of the building on one side. There are also large sheltered balconies at each end of the building on the second floor. Provision has been made in the attic for a clinical laboratory and a room for microscopy. The ordinary patients at the sanatorium are required to pay 70 cents (3*s*.) a day, and a few private rooms are provided at $15 (£3) a week. On the second floor of the dining-room building are the sleeping rooms for the employees.

The water-supply is obtained from spring wells, pumped

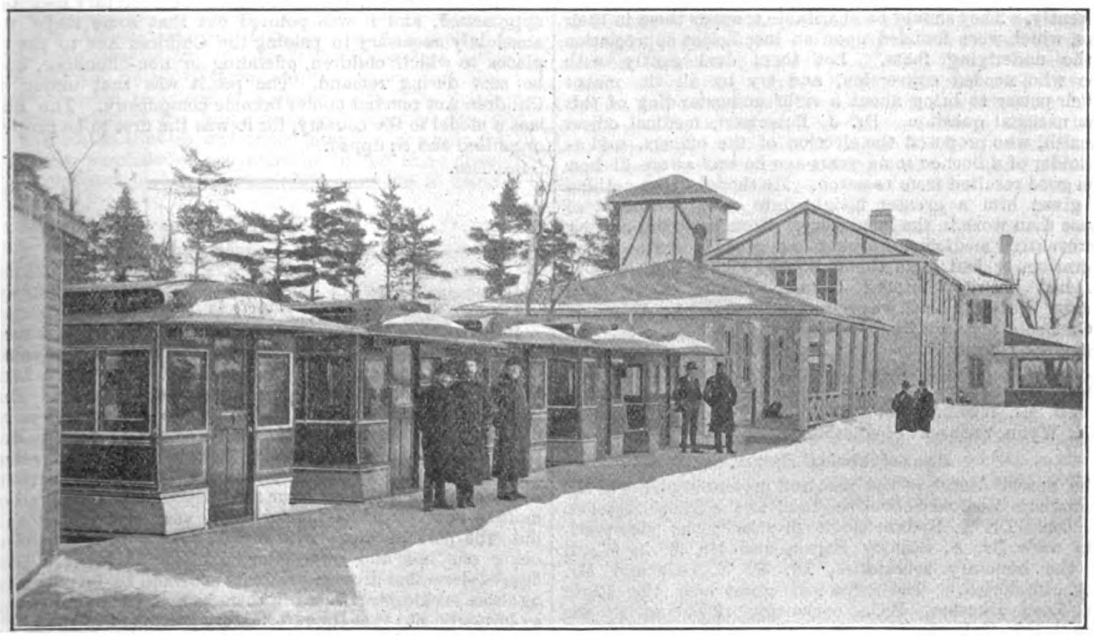
[1] THE LANCET, Oct. 1st, 1910, p. 1041.

FIG. 1.



Wide verandah room, with glass shutters, in which women are taking the fresh air treatment in winter at the Toronto Free Hospital for Consumptives.

FIG. 2.



Old street cars utilised as rooms for men patients, with whom they are greatly in favour, at the Toronto Free Hospital for Consumptives. Each contains a bed, a stove, and some simple articles of furniture.

by windmill, electric motor, and compressed air. There is a complete septic-tank system for dealing with the sewage. Heating is by steam, with several open fire-places, and the lighting is by electricity. The physician-in-chief has a house in the grounds at some little distance from the hospital buildings.

My visit was pleasant and instructive, and I was much impressed by the beauty of the situation and by the efficient manner in which the institutions appear to be conducted. I must express my gratitude to Dr. Dobbie for the trouble he took in showing me all connected with the institutions, and for the patience with which he listened to and answered my questions. It would be well if every large city followed the lead given by Toronto and established in its vicinity a hospital in which poor far-advanced consumptives could be isolated, so as not to be a menace to the health of the population, while having their urgent needs met in every way.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Research Defence Society.

A GENERAL meeting of the members of the Birmingham branch was held at the University on Dec. 2nd, Professor Leith presiding. Reporting on the past year, the President said they began with a membership of 109, and it was now 276. This number they hoped to increase considerably, and efforts should be made to induce working men, nurses, and others to become associate members. During the year they had received a very valuable gift from Lord Justice Fletcher Moulton—1900 copies of his evidence before the Royal Commission on Vivisection. Good use had been made of this as well as of other pamphlets in educating public opinion and obtaining members. Professor Frankland's public lecture on the Life of Pasteur had been very successful, and another public lecture would be given early next year. He proposed the adoption of the report. Mr. Gilbert Barling, in seconding, said that the branch were taking active steps to bring before the public the necessity for experimental work on animals and the benefits to be derived therefrom. Sir James Sawyer, in supporting the proposition, said that the branch had adopted the right attitude in that while they were firm in maintaining the benefits of research to medical science and practice, they did not aggressively oppose those who thought differently. They should be charitable towards them in their views, which were founded upon an insufficient appreciation of the underlying facts. Let them deal gently with those who needed conversion, and try by all the means in their power to bring about a right understanding of this great national question. Dr. J. Robertson, medical officer of health, who proposed the election of the officers, said as the holder of a licence some years ago he was aware of how much good resulted from research. He thought that nothing had given him a greater insight into certain aspects of disease than work in the laboratory. From the point of view of preventive medicine, nothing had given them so much inspiration, or had done the nation so much good, as work that had been stimulated by experiments made upon animals. Professor Leith was re-elected president; Alderman C. G. Beale and Sir George Kenrick vice-presidents; Dr. T. Shadick Higgins, treasurer; Mr. Chatwin, secretary; and Mrs. Gilbert Barling, Mrs. Godfrey Nettlefold, Mrs. Eric Carter, Mr. Gilbert Barling, Mr. Carey Gilson, Mr. A. S. Bennett, Mr. Wilson King, Mr. J. Furneaux Jordan, and Dr. W. H. Wynn, members of committee.

Annual Medical Dinner.

The annual dinner of the past and present students of the Birmingham Medical School was held at the Grand Hotel on Dec. 6th. Dr. T. Sydney Short presided; the vice-presidents were Dr. A. Stanley Barnes and Mr. B. J. Ward, and the honorary secretaries, Dr. C. E. Salt and Mr. R. A. Broderick. The principal guest was the Right Hon. Lord Ilkeston, P.C., consulting physician to the General Hospital. In proposing the toast of "The Medical School," Lord Ilkeston gave many interesting reminiscences of his work in connexion with the old Queen's College, whose staff he joined in 1861 as lecturer on anatomy. Among the other guests present were the Hon. Stephen Foster, recently appointed stipendiary magistrate in the city, and Sir Oliver Lodge. Musical items were contributed by Mr. J. R. Heath, Mr. B. A. Lloyd, and Dr. Browning. The attendance at the dinner was the largest for several years.

General Medical Practitioners' Union.

The annual smoking concert held on Dec. 2nd was largely attended by the medical men of the district. The President, Dr. H. W. Langley Browne, in the course of the evening, presented the general secretary, Mr. James Neal, with an illuminated address and a cabinet of plate in recognition of his considerable services to the profession. Mr. Neal was the founder of the General Practitioners' Union, and its general secretary, as well as editor of the *Midland Medical Journal*. He was a past-president of the Central division of the Birmingham branch of the British Medical Association, the representative of the branch at the representatives meeting, and a member of the Central Ethical Committee. He was also a member of the committee of the Birmingham Medical Institute. Few men have done so much to promote cordial relations between members of the profession and to create public spirit. Mr. Neal, in thanking members for their gift, spoke of the assistance he had received from many of them, especially Dr. G. J. Branson, Dr. W. T. Lydall, and Dr. E. W. Parsey, in promoting their common aims.

Birmingham Children's Remand Home.

The first children's court in this country was established in Birmingham in 1905; another considerable step has now been taken by the opening of a children's remand home. The site and building are the gift of Mr. and Mrs. Barrow Cadbury. It was desired that the building should have as little as possible the appearance of an "institution," and Messrs. Cosins, Peacock, and Bewlay have designed an attractive Georgian house. It was opened by the Lord Mayor on Dec. 9th, who said that the idea was that the house should be associated as little as possible with the police administration. The alternative to a remand home had been the workhouse. That was illogical. The board of guardians had homes of its own to which it sent children in order to keep them away from the workhouse; yet the magistrates had been remanding children to the workhouse. The authorities were very grateful to the donors, through whose generosity a great capital expenditure had been saved, and there would be no expense to the rates. The watch committee, however, had offered to contribute certain statutory sums per head for the maintenance of the children. Mr. Courtenay Lord, who presided, said that the Home Secretary had been approached, and it was pointed out that some steps were absolutely necessary in passing the Children Act to provide places to which children, offending or non-offending, could be sent during remand. The result was that under the Children Act remand homes became compulsory. The home was a model to the country, for it was the first to be properly organised and equipped.

Dec. 13th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Inebriates Acts in Scotland.

IN a report to the Secretary for Scotland, issued last week, the Inspector for Scotland under the Inebriates Act says that during the year ending Dec. 31st, 1909, there were in all nine institutions under his inspection, including three licensed retreats, five certified inebriate reformatories, and one State reformatory. The total number of persons dealt with during the year was 239, of whom 121 were retreat patients, and 118 reformatory patients. Compared with the returns of the previous year the institutions numbered one more, a new retreat having during the year received a licence, but the persons dealt with are 34 fewer, retreat patients being one less and reformatory inmates 33 fewer. These figures show that licensed retreats continue to be patronised by those seeking treatment in them to about the same extent as formerly, but that the reformatory treatment of the police-court drunkard is now being less seldom used.

Retiral of Sir Hector Cameron.

On the occasion of his retirement from the chair of clinical surgery in the University of Glasgow and from the staff of

the Western Infirmary, Sir Hector Cameron was last week entertained to dinner by his former assistants and house surgeons. The chair was occupied by Mr. A. Ernest Maylard, and Dr. Marshall, Dr. J. H. Nicoll, and Dr. Parry acted as croupiers. The company numbered upwards of 40. In proposing the toast of the evening, the chairman spoke of the admiration in which their guest had always been held by those who, like themselves, had been in some way associated with him. As a teacher and a leader in surgery they honoured him; as a man they loved and respected him; and they might justly say that everything he had said was worth listening to, and everything he had written was worth reading. Sir Hector Cameron was endowed with a wonderful memory, and they hoped he would long be spared to give to the profession "valuable material from his carefully garnered store." Sir Hector Cameron, in acknowledging the toast, made an interesting and felicitous reply. Dr. Joshua Ferguson, on behalf of the company, presented the guest with a loving cup, which bore the inscription: "H. C. C., Magistro Carissimo, Discipuli. MCMX." After Sir Hector Cameron had accepted the cup, the proceedings terminated with the singing of "Auld Lang Syne."

Day Nurseries in Dundee.

At the annual meeting in the town-hall, Dundee, on Dec. 5th, presided over by the Lord Provost, the good work done by the day nurseries in the city was recounted. The Rev. Thomas Best, in moving the adoption of the report and accounts for the year, said, when one thought of 30,000 admissions during the currency of a single year, and of what each admission meant in easing the burden of care from a mother's heart and mind, one felt that words were inadequate to give expression to what that implied. The report for the year showed that the mothers had contributed no less than £376 13*s.* 10*d.* 6752 penny dinners were sold during the year.

Rats and Plague in Dundee.

"Careful inquiries at the harbour and slaughter-houses reveal the fact that there is neither an undue prevalence of rats, nor any undue mortality amongst the rats in the city." This was reported by Dr. C. Templeman on Dec. 6th at a meeting of the public health committee. The investigation was made on account of a circular from the Local Government Board asking that investigations should be made into the condition and number of rats in the town.

Honour to an Orcadian Doctor.

On Dec. 1st Dr. David Suttie, who for the last 14 years has been medical officer to the Birsay, Hanay, and Sandwick Medical Aid Association, was presented with a purse of sovereigns in recognition of his faithful services. The occasion was Dr. Suttie's leaving for Glasgow, and Mrs. Suttie was also the recipient of a similar gift. Dr. Suttie, in replying, spoke of the kindness it had been his lot to receive, and stated that it was their intention to apply the money to the purchase of souvenirs to remind them of the happy years spent in an Orcadian home among a warm-hearted people.

Outbreak of Fire at the City Hospital, Aberdeen.

On Dec. 9th an alarming outbreak of fire occurred at the City Hospital, Aberdeen. The outbreak was first observed by a nurse about 9 o'clock, and the fire station was at once communicated with, while the doctor, matron, and nurses brought the chemical appliances into operation and kept the fire in check meantime. The fire arose in the basement of the administration block and was caused by a hot-water pipe setting fire to a beam, from whence it spread to the adjoining joisting, and but for the prompt action of the hospital staff would soon have obtained a firm hold. The damage, covered by insurance, is considerable. The patients were at no time in any danger.

Death of a Dundee Practitioner.

The death took place on Dec. 5th of Mr. Peter Steven, F.R.C.S. Edin., a well-known medical practitioner in Dundee. Mr. Steven was a native of Dundee, a son of the late James Steven, Rosebank, and after serving his apprenticeship with the late Dr. Cocks, a prominent ophthalmic surgeon in the city, he went to Glasgow, where he qualified in 1860. During his student days he made several trips to the Arctic regions in trawlers, and thus gained practical experience in a department of Dundee trade. He enjoyed a considerable general practice in Dundee, although devoting himself largely to surgical work. He died, aged 81 years, after a three weeks' illness.

Glasgow and Aberdeen Universities: Sir Henry Craik Returned Unopposed.

Sir Henry Craik has been returned unopposed as the Unionist Member for Glasgow and Aberdeen Universities.

Dec. 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Hospitals' Tuberculosis Committee.

THE quarterly meeting of this committee was held on Dec. 8th at 76, Grafton-street, Sir John Moore being in the chair. Her Excellency the Countess of Aberdeen, Dr. M. F. Cox, Dr. Herbert Byrne, Mr. O'C. J. Delahoyde, Dr. Frank Dunne, Dr. T. P. C. Kirkpatrick, Dr. J. F. O'Carroll, Dr. G. Peacocke, and the honorary secretary (Sir William J. Thompson) were present. The committee adopted the report of the subcommittee appointed to draw up a resolution with regard to the notification of tuberculosis. This report, which points out "that the detection and isolation of cases of pulmonary tuberculosis in all stages are necessary in the interests of the public health," was directed to be sent to the Local Government Board and also to the Presidents of the Royal College of Physicians and the Royal College of Surgeons. The good work which the nurses do amongst the consumptive poor of the city of Dublin is strikingly illustrated by the large proportion of patients who voluntarily ask for their services. During the nine months ended Nov. 19th, 353 cases of tuberculosis were attended by three district nurses, who paid 4719 visits. The poverty of the patients may be gathered from the statement that 155 families received nourishment, and 116 patients received gifts of clothes, shoes, and bedding. Lady Aberdeen reported that the P. F. Collier Tuberculosis Dispensary in Charles-street was fast approaching completion, and that early next year it would be ready and all arrangements made to commence work.

Association of Fellows of the Royal College of Surgeons in Ireland.

The inaugural dinner of the Association of Fellows of the Royal College of Surgeons in Ireland was held last Saturday night at the Gresham Hotel, Dublin, the President of the association, Lieutenant-Colonel F. G. Adye-Curran being in the chair. There was a fairly large attendance of Fellows and guests, and in the speeches attention was drawn to the disabilities under which Irish candidates suffer in regard to certain hospital appointments in England. The association has taken steps to record its protest against a condition which often appears in Irish advertisements of surgical vacancies—"Candidates must be Fellows of the Royal College of Surgeons in Ireland." The President stated that some of the members wished to enforce in Ireland the "Sinn Fein" policy of Ireland for the Irish, but with that view he had no sympathy.

Dublin Gas.

Last week a good many Dublin householders were annoyed by the presence of an unpleasant smell, and not unnaturally the condition of their drains became suspect. In many cases tests were applied to the drains. When this had gone on for a week or more it was announced on behalf of the gas company that owing to a defect in one of the gas purifiers a certain amount of sulphuretted hydrogen was present in the gas supplied to consumers. The amount must have been considerable, as one medical man reports the occurrence in his own case of unpleasant symptoms, such as headache and nausea.

Food for School Children.

On Dec. 12th a meeting was held at the Mansion House, Dublin, the Lord Mayor presiding, to promote the movement for the extension to Ireland of the Act making public provision for the feeding of necessitous school children, of whom there were a great number in Dublin. At present in some of the city parishes committees of ladies are working to provide meals for necessitous children, and pending

legislative change it is proposed to extend this voluntary organisation to the entire city.

Scarlet Fever in Belfast.

In Belfast there is at present an epidemic of scarlet fever, which—while so far it is of a mild type, with the exception of some toxic cases—is extremely widespread in its locale, cases being reported from every part of the city. In the municipal hospital at Purdysburn all the beds are full, there being 150 scarlet fever patients, and new cases have now to go to the union fever hospital. In some parts of the city, especially the south division, there is an outbreak also of measles; and cerebro-spinal meningitis has also been made notifiable for the year to the end of Dec. 1st, 1911, but, fortunately, the cases are very few in number. Since, and as a result of, the last serious outbreak of "spotted" fever several children have been admitted into the Ulster Institution for the Deaf and Dumb and the Blind with blindness and deafness.

The King Edward Memorial in Belfast.

The fourth list of subscriptions to the King Edward memorial in Belfast, which is to take the form of an additional block to the Royal Victoria Hospital, Belfast, was published on Dec. 10th, and brings the sum subscribed up to £14,789.

Irish Asylums.

The position of asylums in Ireland is becoming deplorable from want of room and of money. The Monaghan and Cavan asylum board at its meeting on Dec. 8th met specially to consider the problem of providing increased accommodation. The Inspector of Lunatics, in a long report dealing with the subject, points out that as estimated the accommodation is calculated by the latest official returns to be sufficient for only 793 patients, while the asylum is now over-crowded by 128. In the circumstances he says it is impossible to report to the Lord Lieutenant that the accommodation provided by the county councils of Cavan and Monaghan for the insane poor is sufficient. The report also pointed out the danger there was of His Excellency withdrawing the capitation grant in the circumstances. After a very long discussion it was unanimously decided that the military authorities should be communicated with in order to ascertain if the disused military barracks could be obtained for the purpose of an asylum. The inspectors and the asylum architect were also requested to visit these military barracks to see if they approved of the buildings and to report what they estimated as the cost of converting them into an asylum.—At the monthly meeting of the committee of management of the Tyrone and Fermanagh Asylum, held on Dec. 8th, the auditor reported that, in spite of the increase in the demand which was made last spring, the accounts closed this half-year heavily in debt, and although it was probable that this debit balance would be somewhat reduced by the end of the financial year, when the full increased rate had been received, still it would remain very considerable, and the committee, when considering the estimates for 1910–11, would have to make a further increase in the demand in order to put the accounts on a satisfactory basis.

Dec. 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Election of a Professor in the Faculty of Medicine.

THE council of the Paris Faculty of Medicine has elected a professor to occupy the chair of diseases of the nervous system, a position formerly held by Professor Raymond, and before his time adorned by Professor Charcot. There were two candidates, both of them being specialists and professors in the Faculty—namely, Dr. Dejerine, professor of medical pathology, and Dr. Pierre Marie, professor of pathological anatomy. The council elected Dr. Dejerine, who has done excellent work in diseases of the nervous system, has been an *agrégé* since 1886, and is 61 years of age. Another professorial appointment is probable, for the Municipal Council of Paris has been considering a proposal that a municipal chair should be created for Dr. Doyen. The high reputation which Dr. Doyen enjoys, not only in France but in various other countries, makes it unnecessary to do more than refer to the great ability which he has shown as an unofficial lecturer and teacher, and his promotion would obviously do credit to the initiative of the Municipal Council.

Treatment of Fractures of the Elbow in Children.

At a meeting of the Société de Médecine de Paris held on Nov. 26th, M. Barbarin made a communication on the subject of fractures of the elbow with displacement occurring in children. He said that in the majority of cases, when treatment by mobilisation did not give immediate good results, it was necessary to remove one or more of the fragments under the guidance of radiography, an operation which was soon followed by recovery or improvement. M. Mouchet said that he was in principle opposed to operations on the bones of the elbow or in fractures of that joint in children unless the lesions were either open or else attended with injury to the nerves. On several occasions (four times during the present year) he has had to operate on improperly reduced fractures of the external condyle and on supracondylar fractures. With respect to epitrochlear fractures, of which he had treated nearly 50, he had operated on only one in which the fragment was visible through a wound in the integument. Massage ought to be gentle in children suffering from fractures of the elbow, and obviously ought to be practised only at a distance from the seat of fracture. Mobilisation ought to be still more gentle; in some children it increased the stiffness. Some children had a predisposition to an excessive formation of osseous substance, an unexplained and unpreventable condition. M. Coudray remarked that the cases which had been described were important because they exemplified relatively rare fractures of the elbow. He agreed with the opinion of M. Mouchet that early operations were undesirable, because well-marked stiffness might either disappear or improve considerably in the course of some months. He thought that it was inadvisable to operate a second time on a child who had been examined and who would certainly regain the power of extending the joint. M. Durez said that it was not always necessary to employ massage in recent fractures, as these might be treated satisfactorily by mobilisation.

Fire at Branch Premises of the Pasteur Institute.

A terrible fire broke out on Dec. 7th at the branch premises of the Pasteur Institute between Garches and Marnes la Coquette. Beginning in a loft over the laboratories where serums are prepared and stored, it lasted the whole night and caused immense damage. The 60 horses which were in the stables were brought out, and 5000 boxes of serums were removed to a place of safety. On account of the destruction of the laboratories the director of the establishment at Garches cannot supply the quantity of serum required, but the preparation of it is being continued in a temporary laboratory which was made ready on the following day. It is fortunate that the stock of anti-diphtheritic serum was saved, as the replacement of it would require from three to four years.

Immunisation of Goats against Malta Fever.

At a meeting of the Biological Society held on Nov. 26th, M. Henri Vincent and M. Collignon communicated the results of attempts which they made to immunise four young goats against Malta fever; two of the goats were males and two were females; they were about six months old and in perfect health. Of the cultures which were used, one was supplied by M. Binot of the Pasteur Institute, and the other by M. Nicolle of Tunis, the latter of which, being the more virulent of the two, was used as a control test of the immunity that was produced. The antigen that was employed was prepared according to the principle made known by M. Vincent for the preparation of antityphoid serum, and the inoculations of it were made either under the skin or into a vein. Their experiments led M. Vincent and M. Collignon to believe that there was a prospect of practically immunising goats against Malta fever by several subcutaneous injections of cultures of the microbe of that disease sterilised by ether, which was a volatile antiseptic, easily manipulated and easily got rid of. Treated in this way the virus lost none of its efficiency for inoculation purposes and encouraged the production of antibodies almost as energetically as a living culture would. For the immunisation of animals this antigen was decidedly preferable to an attenuated living culture of the micrococcus melitensis, because a living culture, even after attenuation, might

transform the animals into germ carriers; it was also superior to cultures killed by heat. M. Vincent and M. Collignon considered that the inoculation of young goats against Malta fever would be the most efficacious means of preventing the alarming extension of that disease among goats and perhaps among other domestic animals, as well as among persons who came into contact with goats or were consumers of their milk and the cheese made from it.

Dec. 12th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Grants by Local Authorities in Aid of Medical Students.

A REMARKABLE step has been taken by some of the country magistrates for the purpose of obtaining a few years hence the services of medical men without much difficulty. As a large proportion of medical students come from families which have to practise economy, grants varying from 1000 to 1500 kronen (from £40 to £60) per year for five consecutive years, are offered to medical students who have passed the preliminary examinations in anatomy, physics, and chemistry. These young men must complete their curriculum within the ensuing three years, must spend a further period of two years in hospital work, and must sign a contract that they will take service with the country magistrates at the place allotted to them on the terms of appointment published for that place; this contract is to hold good for the next ten years after obtaining the diploma of M.D., which every practitioner in Austria must possess. It is necessary to explain that at present the remuneration for medical appointments in country places is so unsatisfactory that many of them are boycotted by the medical organisations, with the result that such posts are either vacant or heavy payments have to be made to private practitioners for the treatment of paupers and similar medical work. As the only object of this new scheme is to induce inexperienced students to sign contracts which would in a short time hand them over to the mercy of the country magistrates, to be sent wherever their employers pleased, medical students are being warned against it by the Medical Council. There is no reliable means of ascertaining whether any, and if so how many, of such agreements have been signed, but it is believed that the number is very small. A similar method has been already adopted by the military authorities to secure the services of medical men for the army and militia. Medical students were, and are still, offered the sum of 12,000 kronen (£500), to be paid in instalments increasing from £50 to £80 a year during their curriculum, and the rest on entering the army, where they must serve for 10 years. It is found, however, that even this not insignificant financial help has failed to solve the problem of the chronic shortage of army medical officers, owing to the unsatisfactory social and educational opportunities of the army medical service.

A New Water-supply for Vienna.

On Dec. 2nd the sixty-second anniversary of the Emperor's accession, His Majesty opened the grand new waterworks. This great undertaking has been completed within ten years, and its importance may be gauged by the fact that it not only doubles the amount of water supplied to this city of 2,000,000 inhabitants, but will no doubt prevent a water famine, at least until the year 1940, when the population will, it is computed, be doubled. The water is collected in the Styrian Alps, a mountain range a little over 6000 feet high, at a distance of some 120 miles from the capital in a south-westerly direction. 20 per cent. of the water comes from seven large mountain lakes and the rest from springs and wells in this area; it is brought in huge pipes, aqueducts, and syphons to the city, where it is capable of reaching the highest spot, even in the hilly portion of the suburb, without any lifting apparatus, owing to the great height from which it comes. The daily quantity flowing into the reservoirs is nearly constant both summer and winter, and amounts to 250,000 tons of pure drinking water. To this must be added the supply coming from the old waterworks, which derive their water from the springs around and on the Schneeberg, a range of snow-covered mountains also about 6000 feet in height. This yields an almost equal supply per head per day for Vienna. Last winter, when abnormal weather conditions had been prevailing for nearly half a year and a prolonged drought had emptied the reservoirs, the city experienced a serious water famine, as the supply had fallen below 100,000 tons per day, and the water-pipes in the houses had to be throttled to prevent undue use of the precious liquid. The new water is of excellent quality. It has a fairly constant temperature varying from 6° to 10° C. Its softness makes it well suited for washing, cooking, and other household requirements, but is not so marked as to interfere with its use as a beverage. The mineral constituents are chiefly carbonate of lime with a little phosphate; there are also traces of magnesia, and in summer-time traces of silicates have been found; it contains no organic admixture, and there are very few germs. Care has, of course, been taken to prevent any possible contamination or pollution in the catchment area, and the water will be analysed every week in the municipal laboratory. The cost of the work amounts to 100 million kronen (over £4,000,000), and a small charge (about 1 per cent. of the rent) has to be paid by the occupants of flats and houses for the outlay. Vienna can now boast of having the most plentiful and best water-supply of any capital city in the world, and perhaps of any city in Europe.

The Proposed New Regulations for the Management of Hospitals.

The professors of the Vienna medical institutes, composing the Medical Faculty of the University of Vienna, have held a meeting in order to protest against the insidious plan of bringing the clinics under the influence of political parties as described in this column on Dec. 3rd, p. 1655. At this meeting vehement opposition was directed against two points which are considered to be extremely objectionable—namely, the administration of hospitals by non-medical men and the whole-time appointment of the hospital staff. A committee, consisting of the present dean of the faculty and the three previous holders of this office, as well as of the presidents of the "Association of the Hospital Medical Men," and the "Organisation" was at once despatched to the Ministry of Education, the Ministry of Finance, and to the Home Secretary to explain the views held by the professors, the committee being authorised to inform the Ministers that all the clinical professors were prepared to resign their posts at once if the scheme should become law, as they could not take part in ruining the profession. As a result, the plan may be considered as dropped, at least in its original shape. Whatever is good in the scheme will no doubt be brought out at another occasion.

Dec. 12th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The St. John Ambulance Association.

THE Government of India has placed the Indian branch of the St. John Ambulance Association on the list of institutions in India receiving an annual Government subsidy. The Government grant to the association is meant to signify the highest official approval of the remarkable extension of the humanitarian work of the association amongst the people of India during the past two years. It is not designed to relieve private individuals of their responsibility to the branch, and it is hoped that numerous chiefs and leading Indians will follow the generous example of His Highness the Nizam, who, in addition to maintaining a flourishing centre in his dominions, has recently made a handsome donation to the central fund of the association.

The Bombay Hospitals.

The annual report by Surgeon-General H. W. Stevenson, I.M.S., Surgeon-General to the Government of Bombay, on the civil hospitals and dispensaries of the Bombay Presidency for the year 1909, which has just been issued, states that during the year the number of hospitals and dispensaries increased from 718 to 723. The total number of patients, both indoor and outdoor, treated during the year was 2,250,211, or 47,270 more than in the previous year. The percentage of mortality was 9·8, practically the same as that of last year. Of the 2,250,211 patients treated, 13,098 were Europeans and

Eurasians, 1,422,600 were Hindus, 682,344 were Mussulmans, and 132,169 belonged to other classes. The number of adult females formed 20·8 per cent. of the total treated. Analysis of the numbers treated under the different diseases shows no marked increase, except under the head of cholera, in which case the numbers rose from 288 to 2347. The disease chiefly prevailed in the Deccan, and its spread was largely due to the Sinhast pilgrimage at Nassik. Tuberculosis shows an increase of 102. Under leprosy the cases treated fell from 4012 in 1908 to 1961. Malarial fevers show a decrease of 5366 cases, but still supply 18·54 per cent. of the total number treated. The total income was Rs. 17,69,358, and the expenditure Rs. 17,46,758. The average cost of the dieting of each patient during their stay in hospital was Rs. 0 2-10, as compared with Rs. 0 2-11 in the previous year. The report comments on the inadequacy of medical relief in different parts of the country, and the announcement is made that in order to meet this need a scheme for the establishment of a number of additional dispensaries is receiving the attention of Government. The scheme, it is stated, is almost completed.

H.H. the Maharaja of Patiala.

The generous gift of H.H. the Maharaja of Patiala to the King Edward Sanatorium for Consumptives at Dharampur, alluded to by the Lieutenant-Governor of the Punjab at the recent installation of His Highness to full reigning powers at Patiala, amounts to a lakh of rupees. His Highness has further undertaken to provide an up-to-date dispensary and has made a fresh grant of pine-covered land. At Dharampur steps are being taken to build a hostel where students and young persons generally who are run down may be enabled to ward off the encroachments of the disease which is working such havoc amongst them.

Presentations to an Indian Medical Officer.

On his departure from Bombay for Europe Lieutenant-Colonel H. P. Dimmock, Principal of Grant Medical College, senior medical officer of Jamsetjee Jeejeebhoy Hospital, and physician-in-charge of Bai Motlibai and Sir Dinshaw Maneckji Petit Hospitals for Women and Children, Bombay, who has held the above posts conjointly since 1903, has been the recipient of a number of valedictory addresses. These included: (1) from the medical and subordinate staffs, an address in silver casket; (2) address and presentation from the nursing staff of the hospitals under his charge; (3) a presentation portrait of himself subscribed for by the students; (4) an address from the military medical students; (5) an address in silver casket from the student gymkhana; and (6) an address from the native staffs.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

The Anti-opium Societies and the Chino-Indian Agreement.

A GREAT many home papers contain accounts of meetings held by anti-opium societies at which resolutions are carried unanimously calling upon the Government to cut short its agreement with China by totally suppressing the Indian export of opium without further delay. The following considerations are well worthy the attention of anti-opium societies who, in the opinion of competent authorities in China who are studying the question on the spot, are doing much to hamper the British Government in its good work, and probably to thwart the proper working out of a scheme which has been acknowledged by China to promise the best means of thorough abolition. For the agreement come to is a sound one. It was seen by both parties that the speedy and total abolition of such a widespread habit is impossible. Therefore it aims at a *pari passu* diminution of the Indian trade and the home production in China. Should the Indian trade be forthwith stopped there is no possible hold on the Chinese to annually diminish their trade. There are at the present moment hundreds of thousands of Chinese who would resume the habit the moment any restrictions are removed. This agreement made by the two Governments has entirely altered the situation. The efforts of every anti-opiumist should now be directed to seeing that it is loyally carried out; interference with it can only be perilous. The sincerity of the Indian Government is unquestionable; the sincerity of China may be more open to question, though for my own part I am convinced of it. The ability of the Indian Government to carry out its promises is undoubted; it has absolute control of the production and of the export trade. The ability of China to accomplish this herculean task to which she has pledged her honour, and to which she has set her hand, is quite another matter. It should be remembered that opium is imported from Persia, Annam, Dutch Colonies, and other places besides India, and that China has no efficient preventive service along her thousands of miles of coast line. The amount of opium grown in China is over 360,000 piculs, while only 40,000 piculs are imported from India. The production of opium is in private hands, scattered over several provinces, and, as has been proved in Shansi, can only be controlled with difficulty at the best, and in the course of several years. In other places, for various reasons, there is far less progress. The fact is that the machinery for effective control, as for effective taxation of the native product, does not exist. Public opinion will do more than anything else, and the present agreement (possibly modified in one or two details) has a real value in keeping up the pressure of public opinion. It is a good help to the genuine anti-opium movement in China. In the name of common sense and of the cause we all have at heart, it is best not to interfere from outside to cut off the pressure which the agreement brings to bear on the officials and people of the provinces where at present the anti-opium movement is weakest. That there is plenty of scope nearer home for the activities of anti-opium societies in the direction of limiting the export of morphine, &c., from England to China is shown by the following resolution put by the Hon. Mr. M. Stewart at the Hong-Kong Legislative Council:—

> That this council desires respectfully to draw the attention of the Secretary of State for the Colonies to the port of origin of all the morphine, and one-third of the compounds of opium, entering this colony; and humbly prays him to lay before Parliament the propriety of assisting this Government in its endeavours to discourage the opium vice in its most injurious form by restricting the export from England of the means of gratifying it.

In the Memorandum on opium published in 1909 by the Statistical Department of the Chinese Imperial Maritime Customs the Commissioner of Customs at Foochow wrote as follows:—

> Prior to 1902 and the increase of duty on morphia the recorded importation at Foochow averaged 2700 ounces per annum. During the following three years only eight ounces were imported, and since 1905 none whatever has been declared at the Customs. There is reason to believe that large quantities are smuggled in along the coast in junks from Formosa and into the open ports by steamers from Hong-Kong. The consumption of the drug is reported to be just as great as ever. Upwards of thirty medicine shops at Foochow deal openly in morphia, and some of these are believed to carry stocks of as much as 1000 ounces. Most of the bottles bear the labels of British firms. Instruments for subcutaneous injection are also found, but are not in great demand.

These two quotations should give the home societies something to think about.

Appearance of Human Plague at Shanghai.

Following several suspected deaths the corpse of a Chinese was discovered by the municipal health authorities and material taken from a bubo was found to contain virulent plague bacilli. The day after this discovery two more cases were found which were verified as plague and which succumbed to it, making a total of three deaths. The acting medical officer of health, Dr. A. Moore, therefore declared the subdistrict to be plague-infected and ordered all the houses in it to be visited daily and all plague and suspected cases to be removed, compulsorily if need be, to the isolation hospital and all contacts to segregation quarters. Although there are many enlightened natives who view with appreciation the steps taken to prevent the plague obtaining a foothold in the settlement, there have been many wild rumours among the lower classes who resented the house-to-house visitation. Finally a riot broke out, necessitating the calling out of the volunteers to assist the municipal police in keeping the hostile Chinese in check. Several of the rioters were wounded as well as a few foreigners, but order has now been restored and the Chinese authorities are doing their best to coöperate with the police by appeasing the populace. The former have issued proclamations and called meetings to explain the situation. It is now confidently expected that the measures taken will permit the routine work of disinfection and supervision to be carried on as before.

Peking, Nov. 20th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Talbot Milk Institute.

THIS undertaking, which was founded on the initiative of Lady Talbot for the provision of fresh milk to the poor of Melbourne, recently applied to the Government for financial assistance. The Premier appointed Dr. Foske and Mr. Weldon, a civil servant, as a special board to inquire into the management of the institution, and these gentlemen presented a strongly condemnatory report, in which, *inter alia*, they wrote: "As the result of the inquiry we are of the opinion that the work of the institute has been unsatisfactory and unduly expensive, and therefore does not justify the continuance of Government support. We consider that the institute is unnecessary, and regard it as an example of how this community has charitable institutions foisted upon it to do certain necessary work that can more easily and effectively be undertaken by existing bodies. We therefore recommend that the request for a further grant be not acceded to." As the committee of management includes almost all the leading children's specialists and many prominent health officials and university teachers in veterinary science, this report naturally created a sensation, and has formed a subject of newspaper correspondence. The two morning newspapers took opposite views, the *Argus* upholding the institute and the *Age* supporting the adverse comment. After the first excitement subsided there appeared to be two points calling for reply from the Talbot committee. One was an allegation made in the critical report that "no record was kept of the number of children supplied nor any particulars concerning them, so that it was impossible to prepare mortality or other statistics or arrive at the cost per head." The other was the opinion that the municipalities could do the work more cheaply and efficiently than the Talbot Institute. After consideration for nearly a month the committee have published a lengthy reply to the adverse comment. They say: "In the portions of Melbourne where the Talbot milk has been supplied during the past two summers there has been a uniform and striking fall in the infantile death-rate." It must be confessed the committee does not produce any convincing figures in support of such a statement. As to the alleged excessive cost, the committee claim that the supply of ice-chests and ice to parents, nursing and other supervision has swelled the total, but is inseparable from any scheme of the kind. They further remark as to the board of inquiry: "Its report should be regarded merely in the light of an *ex parte* and unreliable statement of two persons who appear to consider they hold a brief against the institute, and its conclusions should be considered merely as the verdict which these persons were endeavouring to secure." Members of the institute committee attended at Parliament House and addressed some members of the House on the question. Pressure is being brought to bear on the Premier, and it is probable some advance will be made pending a further inquiry into the working of the institute.

Health of Melbourne.

The annual report of the city health officer for 1909 gives the death-rate at 13·6 per 1000, or, deducting benevolent asylum figures, 12·4 per 1000. This rate shows a continuous decline since 1886. The birth-rate was 22·5 per 1000 and the infant mortality-rate 98 per 1000. Diphtheria and scarlet fever were unusually prevalent, and the Infectious Diseases Hospital was severely taxed for accommodation.

Hospital Sunday.

The annual Hospital Saturday and Sunday collections were taken up on Oct. 22nd and 23rd in Melbourne. The total exceeded that of any year except 1888, which was the "boom" time, being then over £9000. This year's total was £8119, but with some further sums to come may reach a larger figure.

West Australian University.

A Royal Commission appointed to inquire into the feasibility of a university for West Australia has reported to Parliament and recommends: 1. The establishment of the university without delay. 2. The type to conform to that of the Eastern States, but with any modern amendments necessary. 3. Both sexes to have equal rights and facilities. 4. The commission favours free tuition, but if fees are necessary to be as low as possible. 5. Faculties to be formed in arts, science, law, and perhaps music, and at a later stage medicine and surgery.

Medico-Legal Case.

Some time ago a young woman was found dead in the house of a Chinese herbalist in Ballarat. The herbalist himself called the police, and his statement was that the deceased came to consult him and died while he was making up a medicine. Deceased was in a certain condition and evidence was given that she was aware of the fact and went to the house for a certain purpose. The medical man who made the post-mortem examination is of opinion deceased died from the entry of air into the veins, and in this he is supported by two other local colleagues. The Government pathologist, who made a subsequent necropsy, is of opinion that death was due to shock. At the first trial the jury disagreed on the charge of murder preferred against the herbalist. At the second trial additional medical evidence is to be called on both sides.

Obituary.

Mr. H. J. H. Scott of Scone, New South Wales, died recently from enteric fever. He was a well-known cricketer in his earlier days, and captained the Australian eleven which visited England in 1886. Two years subsequently he qualified as L.R.C.P. and M.R.C.S. Eng., and returning to Australia practised his profession at Scone, where he was greatly esteemed, as was evidenced by an immense gathering of the public to attend the funeral. Mr. Scott was only in his fifty-first year at the time of his death.

Nov. 15th.

Obituary.

WILLIAM HENRY HORROCKS, M.B. LOND., F.R.C.S. ENG., L.S.A.,

SENIOR HONORARY SURGEON, BRADFORD ROYAL INFIRMARY.

IN the death of Mr. W. H. Horrocks at the early age of 53 years Bradford has sustained a severe loss. He was universally respected and had a high reputation in the city and surrounding country. In a quiet way he exerted considerable influence, and by always maintaining a high standard of conduct in all that he did he upheld the honour of the profession in the city of his adoption.

Mr. Horrocks was the second son of the late Dr. W. H. Horrocks of Blundellsands, Liverpool, and was born on June 18th, 1857. He received his medical training at University College, Liverpool, the Owens College, Manchester, and University College Hospital, London, taking the M.R.C.S. Eng. in 1882 and L.S.A. in 1883. In 1886 he took the M.B. of the University of London, and the Fellowship of the Royal College of Surgeons of England. After qualifying he held a resident post in the Rotunda Hospital, Dublin, and then served for three years first as ambulance surgeon and later as house surgeon in the Northern Hospital, Liverpool, after which he returned for a year to London to act as assistant demonstrator of anatomy at University College. He then went to Bradford as house surgeon to the Royal Infirmary, holding the appointment for nearly three years and resigning it to enter into partnership with Dr. A. C. F. Rabagliati. After a few years the partnership was dissolved, but the close personal friendship remained. In 1891, on a vacancy occurring at the Royal Infirmary, he was appointed honorary assistant surgeon, and in the following year was elected to the full staff, being at the time of his death senior surgeon to the institution. His zeal for surgery, his thorough training, and his abilities enabled him, despite his delicate physique, to rise to the position of a consultant whose advice was frequently sought by his brother practitioners in Bradford and the surrounding districts. Though never entirely relinquishing his family practice, he was yet so loyal and considerate to both patients and doctors that his consulting work steadily increased, and at the time of his death was considerable. On his appointment as surgeon to the infirmary he at once threw himself with zeal into the work, and the institution owes a great debt to his energy and ability. He took a great interest in the management of the hospital and especially in the training of the nurses, always being at pains to point out to them anything in the cases which had a bearing upon their work. He

wrote many papers in the medical journals, but these do not represent a tithe of those he read before the local medical societies. He acted as medical referee under the Workmen's Compensation Act.

The medical profession in Bradford has, in short, by the death of Mr. Horrocks, lost an able diagnostician, a capable surgeon, and a true friend whose place will not easily be filled. Such honours as the local profession had to bestow were conferred on him. He was chairman of the Bradford division of the British Medical Association and President of the Bradford Medico-Chirurgical Society, and how great were the respect and esteem in which he was held was shown during his last illness by the constant inquiries that were made concerning him, and at his funeral by the very large gathering of medical men that assembled to do him honour.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—As the result of the examination held on Nov. 17th, 21st, 22nd, 23rd, 24th, and 25th, for which 67 candidates presented themselves, of whom 26 were approved and 41 were referred, the Council conferred the diploma of Fellow on the under-mentioned gentlemen at their meeting on Dec. 8th. Two gentlemen, Ernest Marshall Cowell, of University College, and Anandrai Keshavlal Dalal, of Bombay University and Middlesex Hospital, who were among the successful candidates, were not eligible to receive the diploma on account of their not having reached the requisite age of 25 years. The following is a list of the successful candidates:—

Thomas Gerald Fenton, M.R.C.S., L.R.C.P., St. Thomas's and St. Bartholomew's Hospitals; Krishna Moreshwar Pardhy, L.M.S. Bombay, M.R.C.S., L.R.C.P., Bombay University, University College Hospital, and Birmingham University; William Bradshaw Ainger, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Ernest Edgar Maples, M.D., B.S. Lond., M.R.C.S., L.R.C.P., St. Bartholomew's and St. Thomas's Hospitals; George Ernest Oswald Fenwick, M.R.C.S., L.R.C.P., University College and St. Bartholomew's Hospital; Gordon Wilson Thomas, M.B., B.S. Lond. M.R.C.S., L.R.C.P., Leeds University; James Montagu Wyatt, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Edwin Thomas Harries Davies, M.D., M.S. Lond., M.R.C.S., L.R.C.P., St. Mary's Hospital; John Black Ferguson Wilson, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Leeds University and London Hospital; Charles Walter Gordon Bryan, M.R.C.S., L.R.C.P., St. Mary's Hospital; James Barlow Macalpine, M.B., Ch.B. Manchester, M.R.C.S., L.R.C.P., Manchester University and London Hospital; Paul Jenner Verrall, M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Bartholomew's Hospital; Alfred Richardson, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Leeds University; Harry Blakeway, M.B., B.S., B.Sc. Lond., M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Harold Delf Gillies, B.A. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Bartholomew's Hospital; Edward Leslie Martyn Lobb, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Guy's Hospital; Harold Chapple, M.A., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and Guy's Hospital; Murugesem Muthu Kumarasamy, M.R.C.S., L.R.C.P., Madras, Edinburgh University, and University College Hospital; John Francis O'Malley, L.R.C.P. & S.I., M.R.C.S., L.R.C.P., Dublin University and London Hospital; Edward Mapother, M.D., B.S. Lond., University College Hospital; Charles Aubrey Pannett, M.D., B.S., B.Sc. Lond., St. Mary's Hospital; Robert Nuttall Porter, M.B., Ch.B. Vict., Manchester University and London Hospital; Balcombe Quick, M.B., B.S. Melbourne, Melbourne University and London Hospital; Paul Bernard Roth, M.B., Ch.B. Aberdeen, Aberdeen University and London Hospital.

Licences to practise dentistry were conferred upon the following 42 gentlemen who have passed the requisite examinations and complied with the by-laws:—

Albert Frederick Bangert, Middlesex and Royal Dental Hospitals; Charles Holme Barnett, Guy's Hospital; Robert Dudley Bell, Sydney Martin Bell, Harold Edgar Bower, and Ralph Chapman, Charing Cross and Royal Dental Hospitals; Charles Repton Faulkner, Birmingham University; Thomas Leonard Fiddick, Guy's Hospital; Guy Leroy Gillett, D.D.S. Michigan, Michigan University and Middlesex Hospital; Frederick Simpson Glover, Guy's Hospital; John Ferguson Gow and Norman Grellier, Charing Cross and Royal Dental Hospitals; Laurence Edgar Crespine Harrison, Middlesex and National Dental Hospitals; Clement John Henry, Guy's Hospital; Albert Henry Herbert, Birmingham University; Clement Eugene Holburn, Sheffield and Durham Universities; Arthur Percy Livett Johnson, Guy's Hospital; Bertram Howard Jones, Middlesex and National Dental Hospitals; William Joseph Kennealy, Guy's Hospital; Harold William Knowling, Liverpool University; Edward Aubrey Clement Knox-Davies, Guy's Hospital; William Stuart Lang, Middlesex and National Dental Hospitals; Stanley Lawson, Guy's Hospital; Frederic Winbolt Lewis, Middlesex and Royal Dental Hospitals; Harris Raphael Lyons and Leslie Miller, Charing Cross and Royal Dental Hospitals; Arthur Stanley Morgan, Guy's Hospital; Victor Mayfield Morris, Middlesex and National Dental Hospitals; Charles Harry Greville Penny, Guy's Hospital; Fred Quayle, Middlesex and Royal Dental Hospitals; Charleton Edmund Rice, Guy's Hospital; Gordon Evelyn Rowstron, Guy's Hospital; Harry Stobie, St. Thomas's and Royal Dental Hospitals; Patrick Barry Stoner, Harry Sturton, and Ernest Sutton Tait, Guy's Hospital; Claude Taylor, Charing Cross and Royal Dental Hospitals; William Jefferson Wilkinson, D.D.S. Pennsylvania, Pennsylvania University and Royal Dental Hospital; Frederick Charles Willows, Bristol University; Thomas Edwin Wills, Charing Cross and Royal Dental Hospitals; and William Hector Wotton and Edgar Olyve Yerbury, Guy's Hospital.

LITERARY INTELLIGENCE.—Messrs. Merser and Sons (268–270, Kennington-road) will shortly publish an English translation of the well-known work of Professor Mosso, "La Paura," in which the great Italian biologist explains his views of the etiology, physiology, and pathology of fear. The translation has been made by Dr. Arthur Harrison, a former student of King's College, London, and a late member of the Indian Medical Department, who, after much active service, had to retire on account of advanced organic heart disease; and we bring this work to the notice of the medical profession with a trust that its success will materially help one "to whom fortune has been rather niggardly in her gifts," as the publishers' announcement says. The book will be published at 5*s.* net, and advanced subscriptions will be received and acknowledged at the place of publication.

CHOLERA IN MADEIRA.—The cholera has spread considerably in Madeira, and there has unfortunately been some rioting. Our correspondent last week complained of the supineness of the Lisbon authorities, and the attitude of the Portuguese Government is still apathetic. Local endeavour, strenuous as it is, may not suffice to keep the epidemic in check. The Board of Trade is in receipt through the Foreign Office of information to the effect that persons desirous of sending provisions to relatives in Madeira can secure their admission into the island without Customs examination until the end of January on condition that the packages or cases containing the provisions are accompanied by a certificate from the Portuguese Consul-General in London stating fully the nature and value of the contents. Consular stamps must be attached to each package or case.

ANNUAL DINNER OF THE BRISTOL MEDICAL SCHOOL.—Over a hundred past and present students of the Bristol Medical School met on Nov. 29th, at the annual dinner, which was presided over by Mr. James Taylor. The health of the guest of the evening, Sir Alfred Keogh, was proposed by Captain A. E. Hayward Pinch, I.M.S., an old Bristol student, who spoke enthusiastically of Sir Alfred Keogh's work in connexion with the Royal Army Medical Corps. Sir Alfred Keogh, in reply, said that the reforms had been based on two principles—the attainment of professional efficiency and complete fusion of the military and medical elements. That these objects were achieved was due to the support which he received from the great majority of the corps itself. In proposing "The Medical School and other Departments of Bristol University," he spoke of the debt which tropical medicine owed to the work of Dr. William Budd of Bristol, and alluded to the valuable help which he had received in the organisation of the Territorial Medical Service from Major Thurston, R.A.M.C., another former Bristol student. Sir Alfred Keogh made some very interesting remarks on the part which the modern English Universities are destined to play in the satisfaction of the thirst for knowledge shown to so great an extent by the younger members of the working-classes, and on the influence which this generalisation of higher education would have in rendering British industry and commerce more scientific, and therefore more efficient. In conclusion he pleaded for more attention to physiology and pathology in the medical curriculum. Mr. F. Richardson Cross, who replied on behalf of the medical school, gave a brief outline of its history, and asked the students to set a higher standard of behaviour than that observed at the recent graduation ceremony. The Rev. de Lacy O'Leary, in replying for the other faculties, said that they had much to learn from the Faculty of Medicine as to the value of post-graduate study. To the toast of "Past and Present Students," proposed by Dr. W. H. C. Newnham, Mr. G. Munro Smith and Mr. R. F. Bolt replied in admirable speeches. The former laid stress on the work of the Association of Alumni, which has for one of its aims the compilation of a record of the careers of all former students at the University; and Mr. Bolt gave an excellent account of the progress of the University Union

and the various sporting and other interests which have prospered under its care. Dr. de Burgh Birch, professor of physiology in the University of Leeds and an old Bristol student, proposed the health of the President, to which Mr. Taylor briefly replied. The menu "card" deserves mention. The dinner secretaries try to find a new form for it each year, and this time hit upon the happy notion of enclosing it within a pill-box labelled the "Bristol Medical Dinner Pill—to be taken once yearly."

KING EDWARD'S HOSPITAL FUND FOR LONDON.—The Governors and General Council of this Fund have placed this year the sum of £150,000 in the hands of the committee for distribution among the London hospitals. We shall deal further with the awards.

UNFORTUNATE ADVERTISEMENT. — Numerous advertisements of a forthcoming book by Mr. H. C. Ross on cell-reproduction have been sent to the lay press. The advertisements were not in any way dictated or inspired by the author, and have been published without his authority or knowledge to the regret of himself and the publisher.

THE COTTAGE BENEFIT NURSING ASSOCIATION.—A meeting of this association was held on Dec. 13th, at Denison House, Vauxhall Bridge-road, under the presidency of the Rev. John Harding. The report, which was read by the secretary, showed that the work of the year had been very satisfactory. Dr. Alfred Cox, in the absence of Mr. J. Smith Whitaker, read a paper on the Midwives (No. 2) Bill. He said that the medical profession fully recognised the work of the nurse; there was, however, a tendency on the part of some nurses to encroach on the work of the medical man and to assume responsibilities for which they were not qualified. A nurse should always act under the orders of the medical man, and experience showed that for the successful working of a nursing association there must be harmonious coöperation with the medical profession. With regard to clause 17 of the Bill he thought that the local supervising authority should be responsible for the payment of the medical man who was called in by a midwife. Miss E. M. Burnside also spoke on the same subject, and agreed with Dr. Cox that the local supervising authority, rather than the Poor-law guardians, should be responsible for the payment of medical men.

THE "WELLCOME" PHOTOGRAPHIC EXPOSURE RECORD AND DIARY, 1911.—The "Wellcome" Exposure Record and Diary continues year after year to hold its place in the affections of photographers all over the world. It is essentially a book for the pocket, and is a most handy and up-to-date epitome of photographic art and practice. The articles contained in the literary portion of the 1911 edition, which is just published, are all of a highly interesting and useful character, and serve to help photographers over the technical difficulties of exposure, development, &c. They include directions concerning negative making, factorial, time, machine, tank or stand development, bromide printing, toning, and intensification. Nor are such processes as colour photography and the making of lantern slides and of ozobrome or bromoil prints, forgotten. It is neatly and strongly bound in green cloth boards and fitted with wallet, pencil, and clasp. To the inside of the cover is attached the "Wellcome" Exposure Calculator, with its moveable disc, which enables the exposure to be determined under all conditions of light and scene, by a single turn of the scale. In response to the wish of those amateurs who adhere in practice to one particular brand of plate or film, a special slip for attachment to the disc may now be obtained, which indicates the correct exposure for every stop. This attachment is supplied gratis (on application) to purchasers of the book, by the publishers. Another new feature of this year's edition is the special article on colour photography, in which a simplified method of producing the necessary solutions is given. For the convenience of its world-wide readers and users, the "Wellcome" Exposure Record and Diary is published in three editions—namely, the Northern Hemisphere and Tropics, the Southern Hemisphere and Tropics, and the United States of America. When purchasing, care should be taken to specify which edition is required. The "Wellcome" Exposure Record may be obtained from photographic dealers and booksellers and at railway bookstalls. The price in the British Isles is 1*s*.

THE SANATORIUM WORK OF THE LONDON CHARITY ORGANISATION SOCIETY.—A report recently issued dealing with this subject should prove valuable to those interested in the results obtained from sanatorium treatment. The society works throughout London, carefully selects its cases, employs a medical referee, keeps the patient away as long as the doctors advise, maintains the dependent family in the breadwinner's absence, and tries to supply him with suitable work on his return. The society had sent away 385 patients up to Dec. 31st, 1909, and is now sending away over 100 annually. All these 385 patients were looked up early this year; it was found that over 50 per cent. were working or fit for work, over 11 per cent. were ill, 26 per cent. were dead, and 12 per cent. could not be traced. All these patients went to well-known sanatoriums; the average length of stay was over 17 weeks. The society considers that these figures amply justify the continuance of the work, and confidently expects still better results in the future. The cost of the treatment is shared by the district committees and the central council; the council's share amounts to over £900 a year, and only £50 comes in subscriptions. The work is unique in London, but so far is little known except to those medical men and other friends of the poor who regularly take advantage of it.

BOOKS, ETC., RECEIVED.

APPLETON, D., AND COMPANY, New York and London.

A Manual of Nursing. By Margaret Frances Donahoe, formerly Superintendent of Nurses, and Principal of Training School, Philadelphia General Hospital. Price 7*s*. 6*d*. net.

BAILLIÈRE, TINDALL, AND COX., London.

The Ship-Surgeon's Handbook. By A. Vavasour Elder, M.R.C.S., L.R.C.P. Second edition. Price 5*s*. net.

BLACK, ADAM AND CHARLES, London.

Walker's Block Calendars:—"The Imperial" (size of block 6¼ × 5 inches). Price 1*s*. 9*d*.
"Farringdon" Series of Calendar Cards. No. 11. Cabinet size. In oak frame.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BOND, FRANCIS THOMAS, M.D. Lond., M.R.C.S. Eng., F.R.S. Edin., has been reappointed Medical Officer of Health by the Thornbury (Gloucestershire) Rural District Council.

FLIGG, WILLIAM, M.B., C.M. Edin., M.R.C.S. Eng., D.P.H. Cantab., has been appointed Visiting Medical Officer to the Royal West of England Sanatorium, Weston-super-Mare.

FURBER, L. G. H., L.M.S.S.A., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Twyford District of the county of Berks.

HUTCHINSON, JAMES RANDAL, M.B., Ch.B. Vict., D.P.H., has been appointed Medical Officer of Health to the County Borough of Wigan.

MUNRO, D. G. MACLEOD, M.D., C.M. Edin., has been appointed Honorary Clinical Pathologist to the Cheltenham General Hospital.

ORMEROD, HENRY LAWRENCE, M.D., B.Ch., B.A.O. R.U.I., has been appointed Medical Officer for the Henbury District by the Thornbury (Gloucestershire) Board of Guardians.

PEYTON, T. HENRY, M.D., D.P.H. T.C.D., has been appointed School Medical Officer for North-West Kent by the Kent County Council.

ROBINSON, W. E., M.D., B.Ch. Oxon., has been appointed Assistant Physician to the Infants Hospital, Westminster, and Honorary Assistant Anæsthetist to the West London Hospital, Hammersmith.

SCOTT, ALEXANDER R. P., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Second House Surgeon to the Beckett Hospital, Barnsley.

SMITH, EDWIN, M.D. Lond., Barrister-at-Law, has been appointed Lecturer on Forensic Medicine at St. Thomas's Hospital.

WACHER, SIDNEY, F.R.C.S. Eng., L.R.C.P. Lond., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 49, and to be attached more particularly to Canterbury, Faversham, Ashford, Tenterden, and Cranbrook County Courts.

WEST, HENRY O., M.B., B.S. Lond., has been appointed Resident Medical Officer at the Royal Hospital for Diseases of the Chest.

WOODWARD, ALFRED C. T., M.B., F.R.C.S. Edin., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 21, and to be attached more particularly to Birmingham County Court.

WRIGHT, ARCHIBALD FRANCIS, M.B., Ch.B. Edin., has been appointed District Medical Officer by the Bideford (Devon) Board of Guardians.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNES URBAN DISTRICT COUNCIL.—Medical Officer of Health and Superintendent of Isolation Hospital. Salary £275 per annum.

BARNSTAPLE, NORTH DEVON INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Assistant Physician. Also House Surgeon for six months. Salary at rate of £20 per annum, with board, residence, &c.

BRIDGWATER HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

BRISTOL ROYAL INFIRMARY.—Dental House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

CAIRO, EGYPT.—Medical Tutor at School of Medicine and Registrar to Kasr-El-Ainy Hospital. Salary £E.600 a year.

CANCER HOSPITAL, Fulham-road, London, S.W.—Surgical Registrar. Salary 50 guineas per annum. Also House Surgeon for six months. Salary £70 per annum.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—Two House Surgeons for six months. Salary £30, with board, residence, and laundry.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.

DERBYSHIRE ROYAL INFIRMARY.—House Physician and Second House Surgeon for 12 months. Salary in each case £100 per annum, with apartments, board, &c. Also Assistant House Surgeon for six months. Salary at rate of £60 per annum, with apartments, board, &c.

EARLSWOOD ASYLUM, Redhill.—Junior Assistant Medical Officer, unmarried. Salary £130, with board, lodging, and washing.

ENFIELD AND EDMONTON ISOLATION HOSPITAL, Winchmore Hill.—Resident Assistant Medical Officer. Salary at rate of £150 per annum, with rooms, rations, and washing.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—Clinical Assistants for three months.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Assistant Casualty Medical Officer (and House Physician), unmarried, for six months. Salary £30, with board, residence, &c. Also House Surgeon, unmarried, for six months. Salary £30, with board, residence, &c.

INDIAN MEDICAL SERVICE, India Office, London.—Fourteen Commissions in His Majesty's Indian Medical Service.

LEEDS GENERAL INFIRMARY.—Ophthalmic House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and washing.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board and lodging.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick-square, W.C.—Demonstrator in Anatomy and Curator of the School Museum (female).

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—Honorary Ophthalmic Surgeon. Also Anæsthetist. Salary £15 per annum.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer and Resident Medical Officer at Convalescent Hospital, Cheadle. Salary in each case £150 per annum, with board and residence. Also Medical Registrar. Salary £75 per annum.

MANCHESTER VICTORIA MEMORIAL JEWISH HOSPITAL, Cheetham.—Resident Medical Officer (female) for six months. Salary at rate of £80 per annum.

MARGARET STREET HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, 26, Margaret-street, Cavendish-square, W.—Honorary Physician.

NEWCASTLE-UPON-TYNE, CITY HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Assistant. Salary £125 per annum, with board, lodging, &c.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Assistant House Surgeon for six months. Salary £20, with board, lodging, and washing.

PADDINGTON AND KENSINGTON DISPENSARY FOR THE PREVENTION OF CONSUMPTION.—Assistant Medical Officer. Salary £100 per annum.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence. Also Radiographer. Salary £50 per annum.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months; also to be Senior Resident Medical Officer for four months. Salary at rate of £50 and £60 per annum respectively, with board, residence, and washing.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician for six months. Salary at rate of £80 per annum, with board, residence, and washing. Also Clinical Assistants.

ROTHERHAM HOSPITAL.—Senior House Surgeon. Salary £110 per annum, with board, lodging, and washing.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Election to the Court of Examiners.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Assistant Physician.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SOUTHAMPTON, FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square.—Honorary Dental Surgeon. Also Honorary Anæsthetist.

ST. PAUL'S HOSPITAL FOR SKIN AND URINARY DISEASES, Red Lion-square, W.C.—Clinical Assistant.

STEPNEY ANTI-TUBERCULOSIS DISPENSARY.—Medical Officer. Salary £250 per annum.

SUNDERLAND INFIRMARY.—House Physician. Salary £80 per annum, with board, residence, and washing.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician. Also House Surgeon. Salary £75 per annum each, with board, washing, attendance, &c.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician for six months. Salary £40, with board, lodging, and laundry.

WANDSWORTH UNION INFIRMARY, St. John's-hill, near Clapham Junction.—Junior Assistant Medical Officer, unmarried. Salary at rate of £120 per annum, with board, lodging, and washing.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Surgical Registrar. Salary £50 per annum.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

WEST SUSSEX COUNTY COUNCIL.—County Medical Officer of Health. Salary £500 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer. Salary at rate of £100 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Ammanford, in the county of Carmarthen; at Ebchester, in the county of Durham; and at Creetown, in the county of Kirkcudbright.

Births, Marriages, and Deaths.

BIRTHS.

ARNISON.—On Dec. 12th, 1910, at 2, Saville-place, Newcastle-upon-Tyne, the wife of W. D. Arnison, M.D., of a daughter.

ODELL.—On Dec. 14th, at Ferndale, Torquay, the wife of William Odell, M.D., F.R.C.S., of a son.

PARRY.—On Dec. 6th, at Knole, Maidstone, the wife of Captain F. M. Parry, R.A.M.C., of a son.

MARRIAGES.

GRISEWOOD—JAMESON.—On Dec. 11th, at Bombay, Arnold Egbert Grisewood, Captain Indian Medical Service, youngest son of William Grisewood, Esq., of Egremont, Cheshire, to Edith, youngest daughter of Rev. A. P. C. Jameson, of the Rajputana Presbyterian Mission.

MORISON—DOVE.—On Dec. 7th, at St. Paul's Church, Carlisle, by the Rev. W. E. Strickland, assisted by Canon Bower, Fred Hughes Morison, M.D., Carlisle, to Jane Margaret (Daisy), only daughter of Mr. J. C. Dove, of St. Ann's, Stanwix, Carlisle.

DEATHS.

MACKENZIE.—On Dec. 6th, Brigade-Surgeon Lieutenant-Colonel John Mackenzie, M.D., A.M.D., of Cambridge-terrace, Dover, aged 77 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

REMINISCENT OF THE FOUNDER OF "THE LANCET."

THE story of THE LANCET in its turbulent days of infancy, the pertinacity with which its Founder waged war against what he considered to be abuses, the bitter spirit which animated the strong defending forces in their attempts to repel their enemy, and the ultimate success of the cause of justice and medical reform, are matters which have been minutely dealt with in these columns when lapse of time allowed them to be discussed dispassionately. Strongly confirmatory of much that we published on the matter, and of additional value because they contain the opinions of an eminent physician who was a contemporary of Mr. Wakley, are the following extracts from an autobiographical work of much interest published by Messrs. Smith, Elder, and Co. in 1884—viz., "Memoirs of Life and Work, by Charles J. B. Williams, M.D., F.R.S., Physician Extraordinary to H.M. the Queen, &c." A regular coöperator in our labours has brought them to our notice. Regretting the inadequacy of medical representation in Parliament, Dr. Williams proceeds to define the qualities which belong to a medical Member of Parliament. He should be—

"..... one well acquainted with the past history and present state of the medical institutions of the country, and who is sufficiently known and respected to possess the confidence of a large portion,—if not a majority, of the members of the Profession. Such a representative,—always well informed and accurate in his subject, and speaking with corresponding decision and a certain amount of self-assertion,—would always command the attention of the House, and become somewhat of a power in the State. The only M.P. who seems to me to have ever attained to anything like this position was the late Thomas Wakley. The early part of his career, as a censorious and radical journalist, was very different from that of his later years as a very popular Member of Parliament and coroner for the Metropolitan county. The journal,—which he created, and which *made him*,—in spite of its early ribaldries and abusive personalities, was interwoven with a web of truth and justice which gave strength to its attacks and gained the attention and support of the public; notwithstanding the bitter opposition and persecution from old corporations and long-established monopolies brought in array against it. .....

"When I first came to London [1830] the 'Lancet' was already a power, which had made itself felt:—relished by the profession at large, which has rather a democratic taste, and hailed as champion of their rights,—received with curious interest by the public, which is alive to anything strong or sensational:—but by the aristocracy of the Profession, including the accused Hospital authorities and Corporations—branded as malignant and revolutionary; and to be opposed in every possible way, private and public. To be suspected of connection with the 'Lancet' was to be tabooed by societies and respectable bodies; and woe to the student going in for examinations, if he were supposed to have supplied it with reports! Nevertheless the Journal continued to increase in circulation; and no wonder; for over and above the censorious and scurrilous matter, which served for sauce, it supplied useful food for the minds of its readers, in copious medical news and reports of lectures. Wakley showed his ability as an editor, not only in his own slashing and incisive articles in which he attacked abuses and held up to ridicule and condemnation the inefficiency and neglect of institutions and of their officers, but also in his gathering around him a staff of really clever and well-informed men, who could supply to his pages the most recent knowledge, and guide his counsels by the scientific spirit of progress, required by the forward movements of the times.

"At St. George's Hospital I was in the anti-'Lancet' camp, and was strongly prejudiced against that journal. In fact, I never read it; and all my support and contributions were bespoken by Dr. Macleod, physician of the Hospital, in behalf of the 'London Medical Gazette,' which he edited, and which was said to have been started in opposition to the 'Lancet.' At University College Mr. Wakley's sons were my pupils, and I soon began to receive from him marks of courtesy and confidence. He placed several members of his family under my care, and he recommended a number of patients to consult me. Among these were several Members of Parliament. They familiarly called him 'Tom Wakley,' and all testified how much he was liked and respected in the House by all parties .....

"Although I had these repeated proofs of Mr. Wakley's goodwill towards me, I knew little of him personally, till he consulted me for his own health in the autumn of 1861. I was agreeably surprised with the gentleness and geniality of his manners, and the homely simplicity of his conversation. His ill-health had impaired the vigour of his expression; but there was an earnestness in his look, with an occasional twinkle of his eye, showing forth the workings of energy and of humour in his nature. The hopeful courage and self-confidence, which had borne him up through life against any amount of opposition and difficulty, did not forsake him in the danger which now threatened him. I have not the notes of his case by me; but so far as I can recollect, it was one of inflammatory origin, rather than of tuberculous consumption: but it certainly went on to the formation of cavities, which rendered the prospect of the future very serious: and the more so, as his sanguine temperament and active mind tended to make him impatient of the restriction necessary for any chance of recovery. ..... In the balmy air and quiet of Madeira he so far improved as to pass the winter fairly without any material increase of disease. His death, which took place in May, was from hæmorrhage, brought on, after a boating excursion, by a fall in landing on the steep sloping beach (which I remember well, and the difficulties experienced in landing). The occurrence shows that he was still in possession of considerable activity and strength, and suggests the possibility that his ardent temperament was still apt to lead him beyond the bounds of prudence.

"Without doubt the works of Thomas Wakley entitle him to the foremost rank as a great Medical Reformer; and the successful results of his labours in correcting abuses and neglects of institutions, and in promoting and improving the means of medical education and diffusion of knowledge, have earned for him the gratitude of the Profession and of the Public. No one has ever so consistently and successfully defended the rights and best interests of the Medical Profession in Parliament, in Courts of Law, and through the Press; and if in his early life, his daring and asperities raised against him a host of enemies, they were mostly pacified, and many converted into friends, in his later years, when the beneficial fruits of his efforts became apparent."

LARGE INCISIONS.

To the Editor of THE LANCET.

SIR,—It is somewhat rash, I admit, for a general practitioner, especially after only one or two cases, but I should like to ask operating surgeons whether extensive abdominal incisions are justifiable.

I have had two patients recently, in each of whom the incision was made from the pubes to above the umbilicus, and each survived less than 12 hours. Such an event cannot be considered satisfactory from a surgical point of view. In one of the cases there was no doubt as to the human improbability of survival, but still it would have been more satisfactory had the patient succumbed as a result of a fight with the disease. Such an extensive incision, with the unavoidable consequent exposure of the abdominal viscera and prolonged exploration, does not, in my humble opinion, give the patient a ghost of a chance. Of course, it is important that local encysted collections of pus should be liberated, but the fact of a collection of pus being encysted shows that nature has been successful to some extent. It would appear better to leave such a collection alone in the absence of sufficient diagnostic points to localise it than to explore the general abdominal cavity. In the case referred to the chief seat of disease was in the pelvis, from which had spread a general septic peritonitis, with pus in the upper abdominal regions, but not encysted. The acute symptoms had lasted only about 12 hours previous to the time of admission to hospital and 24 hours from the time of operation—that is to say, the patient was up and about as usual 12 hours before going to the hospital and six hours before I was sent for.

As regards the other case, there was no reason that I could see, except the extensive incision and exposure, why the patient should not have survived. Of course, the operation was absolutely necessary, but what I am calling in question is the extent of the incision.

I have had a third case which may be mentioned here, general peritonitis having supervened on an obscure cause. The patient was sent to a hospital. An incision was first made in the left iliac region where nothing was found except the peritonitis, but when another incision was made in the right iliac region the seat of the trouble was found. The patient recovered. In my own mind I have no doubt that had such an extensive incision as was made in the other two cases been made in this case the result would not have been successful. It would be better to improve our diagnostic methods in localising disease, so that we need not resort to extensive explorations.

I am, Sir, yours faithfully,

Dec. 1st, 1910. X.

SCHOOL-GIRLS AND DOMESTIC HYGIENE.

AT Brighton a school for home training is now at work. It was opened in September, and it is hoped that 80 girls will every year pass through the school after leaving their elementary studies. So far, only a score or so of children have availed themselves of the course of lessons, whereas no fewer than 300 had left school. A member of the board has proposed that the course of home training should be compulsory for girls during the last three months of their school life, and this seems to be exactly the indication of the Board of Education Memorandum on the Teaching of Infant Care and Management in Public Elementary Schools which has just been issued. After referring to the importance of girls and women being taught how

to take care of infants, it says: "The ultimate aim of a State system of education given to girls in the public elementary schools should be to equip them in the best possible way for the duties which fall to them in after-life. What is commonly called book-learning has in past years been too much regarded as the supreme purpose of our elementary schools, and it is beginning to be widely realised that the teaching given in these schools might with advantage be made more practical in certain directions; and that it might, especially in the case of the elder girls, be more definitely directed towards arousing in, and increasing the knowledge of, the ordinary routine of domestic hygiene, including infant care. Few of these girls have mothers who are in a position to give them an efficient training in home management, and the home conditions must often render it very difficult for this to be done. It is thus desirable to consider in what way this subject may be most appropriately and usefully taught at the school in order to supplement, or correct, the inadequate, or inaccurate, knowledge of domestic matters acquired in the home; remembering always that the training should be of a twofold nature, namely, a training in domesticity and a training in infant care, and that it must be designed not to replace but to stimulate and encourage teaching by the mother in the home." Excellent work is already being carried on in Brighton with the object of diminishing the rate of infant mortality, while the school for home training has commenced its operations in the hope of increasing interest in matters domestic among girls between the ages of 14 and 16. The main idea of the school is to equip the girls as far as possible for the life they will lead in their own homes, teaching them at the same time economy, thrift, and the correct methods in practical household management. Thus, to a large degree, it would seem that the highly useful memorandum from the Board of Education has been anticipated at Brighton, and that if application were made to add domestic hygiene to the school curriculum for girls at a certain age, assent would readily be given. The progress of the scheme at Brighton will be watched with much hopeful interest.

SHOULD THE RHEUMATIC AND GOUTY DRINK CIDER?

To the Editor of THE LANCET.

SIR,—Medical opinion seems to be much divided on this question. Perhaps some of your readers would give me their experience.

I am, Sir, yours faithfully,

Windermere, Dec. 12th, 1910. THOS. DOBSON, M.D. St. And.

Constant Reader, in requesting information as to the date of the forthcoming International Hygiene Exhibition in Washington, has omitted to send his name and address. He is referred to the Diary of Congresses published this week.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Dec. 18th-19th (Rome).—National Meeting of Sanitary Officials.
" 19th-22nd (Rome).—Twentieth Congress of Internal Medicine.

In 1911:—

Feb. 20th-25th (Cairo).—Fifth International Congress for the Blind.
March 2nd-6th (Berlin).—Thirty-second Balneological Congress.
" 23rd (Paris).—First Congress of French Medical Journalists.
April 4th-7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
" 18th-20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
" 19th-22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
May-October (Dresden).—International Hygiene Exhibition.
May-October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May-October (?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
June 5th-8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th-29th (Belfast).—Congress of the Royal Sanitary Institute.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
" (Turin).—International Congress of Pathology.
Sept. 11th-15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Goutles de Lait*).
" 11th-16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 18th-23rd (Sydney).—Australasian Medical Congress.
" 18th-24th (Turin).—Fourth National Congress of Hygiene.
" 24th-30th (Rome).—International Congress on Tuberculosis.
" 25th-29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st-4th (Liège).—Second Congress of Alimentation.
Dec. 4th-9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Genoa).—International Exhibition of Marine Hygiene.
(Date not fixed) (Rome).—International Exhibition of Social Hygiene.
(Date uncertain) (Turin).—International Exhibition of Industry and Labour.

In 1912:—

July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
" Visit of German Medical Men to America.
Nov. 22nd-29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—

(London).—Seventeenth International Congress of Medicine.
(Dresden (?)).—International Conference on Cancer.
August (Buffalo).—Fourth International Congress of School Hygiene.

In 1915:—

(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Dr. R. Wells: Differential Diagnosis of Early Forms of Insanity.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Baldness, its Causes and Treatment.

ANCOATS HOSPITAL, Manchester.

The next Clinic will be held on Thursday, Jan. 12th.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

An Address
ON
THE DISORDER OF MEDICAL CHARITY.

Delivered before the Stratford Division of the British Medical Association on Nov. 3rd, 1910,

BY LAURISTON E. SHAW, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

GENTLEMEN,—I am obliged to the Stratford Division of the British Medical Association for giving me this opportunity of meeting some of its members, and hope that those who are present this evening will extend to my efforts to interest them in a branch of medical sociology a fair measure of that splendid commodity the disorder of which in its application to medicine forms the subject of my remarks.

Perhaps I ought at once to say that I do not propose to deal at any length with what one may call internal medical charity—the charity which one member of the profession may extend to his individual colleagues or to his brethren as a whole. As far as individual internal medical charity—a charity of spirit rather than action—is concerned, there is evidence that its growth is almost entirely proportionate to the opportunities which are afforded by such local meetings as this you are holding to-night for medical men to get to know each other intimately. There is nothing so effective as personal intercourse for promoting brotherly feelings amongst professional colleagues.

May I also say a few words on the question of collective internal medical charity? It appears to me that all who are jealous of the good name and fair reputation of our profession should spare no effort to secure that adequate arrangements are made for us to deal ourselves with those cases in which sickness or early death throws members of our profession or their dependents upon the indulgence of the community. Our profession should in this respect be self-supporting. Through some organisation it should be possible to make mutual provision for all such personal calamities. I lay stress on the mutual character of such provision. Whilst contributions should be collected from all members of the profession proportionate to their means, it should be recognised that the benefits of such a provident system should be restricted to those who had previous to their calamity shown the joint virtues of prudence, regard for others, and respect for professional interests by themselves subscribing to such a fund. Some such scheme of mutual medical benevolence seems almost a necessity if we are to hold up our heads as men of common prudence and common sense amongst the members of sister professions.

And now let us turn to external medical charity and divide it as before into individual and collective. It is to collective external charity that the title of my address is especially applicable, but before turning to its consideration I should like to refer to some aspects of individual external charity worthy of our consideration. To every one of us there will naturally be known a certain number of people whose circumstances will from various causes become straitened, and if such people will in the ordinary course turn to us for medical help we shall provide it, and any other charitable assistance that our compassion may suggest, on such terms and in such full measure as our means will allow. Such personal help in money or in kind is a matter entirely for our individual consciences, and we shall be guided by our knowledge of the circumstances and the character of the recipients, and shall do just as much harm or good as any other individual dispenser of charity who restricts his charitable instincts to cases within his own personal knowledge. But however private may be our practice, we can none of us be allowed to restrict our individual charity to this comparatively safe field, however extensive it may be. In addition there will be brought to our notice, often by people quite unknown to us, a large number of cases, also quite unknown to us, which we are asked to treat as private patients for nothing or at greatly reduced fees. Every general practitioner is familiar with the note, often on the choicest paper, which raises in his heart hopes of a new patient able to afford to pay a decent fee and which, beginning "Dear Dr. ——, knowing your kindness of heart," ends by putting upon his visiting list a "Kingdom comer" who will remain upon it till "relieved by art or released by death." Such vicarious philanthropists often sin rather more from ignorance than from real meanness, and they are too frequently encouraged by the complacency with which medical men respond to their requests. The means to do ill deeds makes ill deeds done, for, as I hope to show in a moment, ill-considered and promiscuous medical charity is an ill deed. Often it would be found that this patient taken on without fee at the philanthropist's request is paying a reduced fee to a brother practitioner with whose kindly attention the patient is entirely satisfied. A medical practitioner once told me it was his habit when asked by a third person to see a patient without fee to forward a contribution requesting that it might be used to secure for the patient paid medical advice which he was confident would prove more satisfactory than his own unpaid efforts. This course, though doubtless economical in the end, would be difficult for many of us to pursue, but all must recognise that steps should be taken to check vicarious private medical charity of this description by awakening the public conscience in the matter. Heaven knows that many poor people thus privately introduced to us are sadly in need of medical and other help, but this promiscuous private charity, like promiscuous public charity, is one of the most fruitful causes of the failure of suitable provident schemes whereby such poor people could secure without the pain of charity adequate provision in time of need.

Recently there came to my notice an incident which raised in me a hope that the evils of promiscuous individual charity might some day be brought home even to members of the medical profession. I chanced upon a personal explanation in the daily press from a bishop of a northern diocese of the Church of England. It appears that he had been snapshotted in the act of handing something to a beggar in the street and the photograph had been reproduced in a newspaper under some such title as "A Bishop giving Alms." Whereupon the bishop thought it necessary to explain that his action had been misinterpreted. He was not giving promiscuous alms, which might rightly be regarded as a social crime, but was merely handing to a beggar the address of some institution where his case could be investigated. I have sometimes thought the savage instinct for promiscuous charity which is so firmly implanted in us as a profession was an indication of our joint origin with the primeval priest. If our sister profession of the Church should set us an example in this matter there is hope that even we may in time see the errors of our ways.

But I must come to the main subject I am dealing with this evening—collective external medical charity, which is of greater moment because its greater volume causes greater harm, and because its reform requires our concerted action. To such an audience as this, medical men working in one of the densest areas of our industrial population, I need bring no evidence as to the excessive volume and uncoördinated character of medical charity. Nor will it ever again be necessary for conferences or commissions to collect evidence on this matter. Read where you like in the ponderous volumes of the Poor-law Commission's Report, wherever medical matters are dealt with, in special investigators' memoranda, in appendices of evidence, or in the "Majority" or "Minority" conclusions, you will find the most convincing indications that medical charity is excessive, without order, ineffective, obstructive. It is mere waste of time to pile up facts to make this indictment more damning; examination of the facts already established is only worth while in so far as it helps us to find remedies. If to-night I ask you to consider certain features which may explain why present conditions are so unsatisfactory, it will only be because such explanation needs to be appreciated before the defects can be dealt with.

Now at the outset I should like to say that the mere excess of the volume of medical charity is a splendid tribute to the quality of heart of all those who are responsible for it. Sympathy with pain and suffering of the individual and with the prospective grief of the friends and relatives in danger of seeing their beloved ones die is a quality none could see lessened one iota without fear for the future of our race. It is this sympathy which prompts us all, and will always

prompt us all whenever we are brought in contact with a sick person needing help, to throw to the winds all the most cherished convictions of the political economist and the charity organiser, and then and there to provide whatever is necessary without regard to ourselves, our colleagues, the patient's independence of character, or the destruction of the principles of thrift in the community at large. It is just because we recognise the impossibility of allowing our hearts to be controlled by our heads when face to face with cases of individual physical suffering that we should give the closest consideration in our cooler moments to the ultimate results of our actions. In any attempt that may be made to render the administration of medical charity more orderly the limitations of a civilised community in this direction must be reckoned with. We may, however, hope gradually to educate the impulsive philanthropist to take a wider view: encouraging him to neglect for the moment even an individual sufferer, we must lead him on to consider possibilities of prevention rather than cure of disease, and show him how his open hand and generous heart discourage arrangements which but for them would undoubtedly be made for dealing with sickness in those earlier stages when it is easily curable without entailing economic disaster.

But the imperative call of physical suffering and impending death does not appear to be by any means the sole cause of the excessive supply of medical charity. While there is no form of charity which makes so insistent an appeal to the charitable, and none which, from its immediate apparent results, seems so eminently satisfactory, there is none which in the carrying out is so cheap. I do not mean that the total cost of medical charity to the philanthropic subscribers is small, but that the quantity that can be bought for a given sum is very great compared with other charities. Think what one can buy for a thousand pounds by endowing a bed in a surgical ward of one of the great voluntary hospitals. In every year for evermore one could look forward to providing for 17 patients the usual average three weeks' residence in the ward, each occupant securing a first-class operation at the hands of a surgeon whose average fee for such operations would probably be 50 guineas, together with the same surgeon's visits two or three times a week, the visits twice a day of a qualified house surgeon, the help whenever needed of radiographers, actino-therapeutists, or other specialists, any form of laboratory investigation that may be required, and the constant attention of sisters, nurses, and dressers. Altogether for a sum, say of £30 a year, one can provide services which if they were provided at the normal rate for paying-patients in a private nursing home might easily amount to considerably more than the £1000 by the single payment of which the endowment is secured. No one can blame the philanthropist for laying out his money to such advantage. On such terms the wonder is that the actual growth of the volume of medical charity is not even more rapid than it is. If for the single payment of £100 one could secure each year for evermore 100 pounds' worth of the commodity provided by the Children's Country Holidays Fund, or by the London Playing Fields Association, one would feel disposed to invest every penny of one's savings at such splendid interest. The question is not why is such cheap charity so largely bought, but why is it so cheap to buy? Why can every philanthropist who thinks of building a hospital or founding a dispensary be confident that he can secure unlimited medical service free of cost?

If one were to accept as correct the remarks usually made by eminent laymen on ceremonial occasions connected with the laying of foundation-stones or the opening of new wings of hospitals, and allowed to pass without contradiction by members of the medical staff present, one must believe that medical men give their services to medical charities in the lavish manner I have described because they possess in even greater measure than other members of the community a spirit of self-sacrifice and devotion to the cause of suffering humanity. But even the orator must sometimes doubt the truth of his explanation, while I am confident that the members of the staff present on such occasions must often find it difficult to accept these implied compliments with composure. Some more satisfactory explanation must be found. It has lately been clearly set out for me by a correspondent criticising some remarks I made on the subject of medical charity in a recent Presidential address. My critic is a former pupil, whose distinguished career in medicine and in public affairs I am watching with great interest. He is not attached to the staff of any public medical charity, nor is he engaged in private practice. He writes to me: "In one point I venture to question in their entirety your conclusions as to the injustice of medical charities being run at the expense of the medical man who works them, in contrast to other charities run by parsons and schoolmasters. Parsons and schoolmasters have definite salaried jobs and are not engaged in private practice. They have, therefore, nothing to gain from the experience, advertisement, and honour of philanthropic charity." I am not at the moment defending myself from my friend's criticism, but I am making use of his admirably concise explanation of the motives which lead medical men to give their services so freely to charitable institutions. It is, as he clearly implies, because of the return they receive in the way of "experience, advertisement, and honour."

Must we not, as a body of medical men honestly endeavouring to understand the economics of medical charity with a view to its improvement in the public interest, admit the accuracy of my friend's description of the situation? Can anyone doubt that a chief cause of the cheapness of medical charity to the philanthropist is that it affords to the small section of the profession specially engaged in its administration experience, advertisement, and honour? It is for the public and the profession as a whole to consider how far the creation in this way of a small privileged class of the profession is really for the general advantage. Experience is a commodity which the public as a whole may well demand should be diffused throughout the general body of the medical profession mainly responsible for their treatment. Anything like a ring or corner in medical experience cannot be for the common good. The present system tends too much to make the experience gained by the staffs of public charities the prerogative of the very wealthy, who alone can pay high fees, and of the very poor, who alone can be regarded as proper recipients of charity. In the public interest arrangements should certainly be made for the privileged class freely to share their experience with their less favoured brethren by securing constant coöperation between the staffs of hospitals and the practitioners engaged in private practice amongst the neighbouring population.

How far the public gains by the advertisement of those engaged in charitable practice is in the main an economic question. I believe it is generally recognised in the commercial world that unless advertisement causes bankruptcy it is ultimately and in the long run paid for by the consumer. The peculiarity of advertisement by charitable medical practice is that the obvious and first cost is borne not by the advertiser but by his less prosperous colleagues, to whose possible patients he gives free service. Such patients could not in any case be the advertiser's paying patients and the amount of his advertisement is not, therefore, limited by any direct personal pecuniary consideration. Large as is the amount vicariously paid by the general practitioner for the consultant's advertisement, it is probable that in the long run the public as a whole pays the profession as a whole for the advertisement. Glaring financial injustices to individuals are incidentally caused by the system. Patients too honourable or too simple to seek charitable assistance at the hospital are often seriously crippled financially by the high fees which surgeons find themselves obliged to charge because of the large amount of free treatment given to others often far better able to pay. Even if the privileged member of the profession is amply repaid indirectly for his services, the general public and the main body of the profession are justified in looking askance at an arrangement which is largely responsible for the flood of medical charity, and has many other points of disadvantage for the community as a whole. Enough has been said, I think, as to the etiology of that part of the disorder of medical charity which consists in its excessive volume.

The next disorder of public medical charity which must claim our attention is the want of coördination between different medical charities and between medical charities and other agencies for providing medical assistance. This want of coördination is partly due to a want of proper definition of the aim of medical charity and partly to the natural individualism of all charity which makes it so resistant to schemes of organisation. The latter cause could doubtless be overcome if a successful attempt were made to define the real intention of the purveyors of medical charity. It should

be made clear whether medical charity is in competition with, or supplementary to, the Poor-law; whether it is desired to encourage or make unnecessary provident schemes whereby poorer patients can secure by insurance the benefits of ordinary medical attendance; and lastly, whether it is intended to provide ordinary medical attendance under all circumstances or only special services in the case of unusual or complicated injuries and diseases. Until these points are settled for medical charity as a whole, and for each individual institution which dispenses it, no proper coördination can be secured. Nor until this is done is it possible to deal with the third great defect of medical charity—namely, its failure to restrict its benefits to the proper recipients. All forms of inquiry as to the economic or medical fitness of those seeking medical charity are peculiarly difficult. One naturally revolts at adding any unnecessary physical or mental trouble to a patient in pain or discomfort. Unless it is quite clear what will be the upshot of our inquiries they seem particularly heartless. As a result of these considerations efforts at selection by means of inquiries are practically abortive, and none can doubt that by whatever criterion one measures the fitness for medical charity, the most glaring anomalies can everywhere be found.

The charges which are brought against medical charity by all who have investigated its problems are, first, that there is too much of it; second, that its operations lack proper coördination; and third, that the selection of its beneficiaries is unsatisfactory. I have endeavoured to lay before you some of the chief causes which lead to these disorders, and in the short time that still remains to us I would ask you to consider possible remedies. There are not wanting people of influence who are so distressed with the defects of medical charity and the apparent hopelessness of dealing with them, that they advocate a policy of ending rather than mending. Set up, they say, at the public cost means for doing in an orderly and efficient manner all that which charity now does, and collective medical charity will gradually disappear. They have precedent for this belief in the result upon charity schools of the establishment of a State system of elementary education. In estimating the likelihood of these people being able to gain their wishes we must not lose sight of the fact that the balance of political power is gradually passing from the hands of the classes who have hitherto governed medical charity into the hands of the masses who have received its benefits. Nor must we forget that our new masters are quite conscious of the truth of the motto of one of our great endowed charities, "It is more blessed to give than to receive." Is it not possible for us as a profession to put before the public a considered scheme for the control and direction of medical charity in such a manner that it shall not interfere with other schemes of medical help, and yet shall command the sympathy of large-hearted philanthropists anxious to promote the people's health and happiness?

There seem to be two outstanding features which must be met in any arrangement which can be expected to secure general acceptance. First, it must not interfere with any State scheme for dealing with the immediate treatment of the very poor nor with any provident schemes whereby the moderately poor may be enabled to insure by small payments for the cost of ordinary medical attendance. Secondly, it must recognise the splendid results which have in the past arisen from the partnership of medical charity, medical education, and medical research, and must foster a continuance of this association. Now, there is a custom honoured by long usage in the medical profession, and likely to be considerably extended as the complexity of medical practice and the development of specialism increase, whereby when cases under treatment by one practitioner develop conditions causing difficulty in diagnosis or treatment, or anxiety as to the ultimate outlook, a brother practitioner specially versed in the particular class of case, or more experienced in practice generally, is called in to confer or assist in any way mutually agreeable to the medical men concerned and their joint patient. Here, surely, is a rôle for medical charity. Let it provide the help corresponding to the second or consulting practitioner, refusing in any case to deal at first hand with patients, but freely offering assistance to those who in the usual way of private practice, by some provident system, or through the State, have secured the services of a medical attendant to deal with ordinary ailments and are found by him to require and to be unable to pay for further assistance. Here is a definite aim which would at once eliminate the greater part of overlapping and would enable charity satisfactorily to coördinate its activity with all other agencies for medical relief. Provident schemes would be given full opportunity for their development, while those interested in reforming the Poor-law would feel assured that their efforts would not be handicapped by competition with charity.

But how far would our second essential feature be fulfilled? Would medical charities conducted on these lines have due opportunity for continuing their good work in medical education and medical research? With one possible and unimportant exception I believe that some such arrangement as this would improve vastly the opportunities in both these directions in such of our medical charities as are also medical schools, and would raise to a higher level of excellence medical and surgical treatment in all charitable institutions. Incidentally it would provide for each member of the medical staff "experience" which he would always share with a brother general practitioner, "advertisement" far more valuable to himself and much less costly to his unprivileged professional colleagues, and "honour" unalloyed by any feeling that he was dealing shabbily with his less fortunate brethren. The cases sent to the charity would all be selected on account of some special interest or difficulty, and the appalling flood of trivialities which break the heart of the out-patient staff at all important hospitals would be relegated to general practitioners who could deal with them efficiently and at leisure and receive proper remuneration for the work.

The one point in which it seems possible this arrangement might fail fully to meet the requirements of medical education is as follows. The number of trivial ailments treated in the charities would, as has been said, be definitely diminished, and opportunities of practical instruction in the method of dealing with such simple cases might consequently be lessened. Personally I do not think much stress is laid upon this class of instruction in the medical schools at present. In any case it is clear that its loss could easily be compensated for by requiring each student to spend some time in attending the practice of a provident dispensary or similar institution. This would be a small matter for reorganisation compared with the far-reaching reforms effected by the proposed change. Can there be any fear that such an arrangement would alienate the sympathy of subscribers and check the voluntary support of hospitals? It should, indeed, have an opposite effect. The charitable public likes to see its money well spent. It is seriously and rightly disturbed by the reports of overcrowding, overlapping, and want of coördination in hospital methods as shown by its tendency to entrust its donations to central funds rather than to individual institutions. The principle of the out-patient department providing the sick poor with additional help in difficult cases has already been recognised as a reasonable basis for a special appeal for funds, and in the last annual report of one of our largest hospitals the prospective subscriber is informed that "the out-patients' section of the hospital in increasing degree fulfils its true function of 'the poor man's consultant.'"

If the profession should recognise in the development of medical charity in this direction a possible solution of many of its own difficulties and a hopeful way of maintaining the usefulness of our great voluntary medical institutions, of which as a nation we are justly proud, by what means is it possible to bring about the reform? The first essential step is the education of the governors of the charitable institutions. If they once appreciate that the value of the work of their institutions would be enhanced by this method they would not fail to adopt it, provided they could be assured that they ran no risk of losing subscriptions by so doing. I believe I have shown that any such fear is not warranted. But institutions are ever nervous of taking a new step unless they are assured that their competitors will follow them. Here we should receive great assistance from the central collecting funds such as King Edward's Fund and the Hospital Sunday and Saturday Funds. The announcement by these bodies that for a charity to conduct its work on these lines would be regarded as a virtue to be rewarded by extra grant would give moral and pecuniary courage to the individual hospitals. But the great force which I feel confident will in the end direct medical charity into this defined but effective field of activity is the public spirit of the medical men responsible for the work. It

is impossible to believe that men who possess the extraordinary advantages conferred on them by hospital appointments will tolerate much longer the continuance of a system which brings them "experience, advertisement, and honour" at such a heavy cost to their less fortunate colleagues, and hopelessly blocks the way to numerous urgently needed reforms in the medical treatment of the sick poor

An Address

ENTITLED

"MEDICAL STUDENTS AND MEDICAL PRACTITIONERS."

Delivered before the Aberdeen Students' Medical Society on Dec. 9th, 1910,

BY G. H. COLT, M.B., B.C. CAMB., F.R.C.S. ENG.,

ASSISTANT SURGEON, ROYAL INFIRMARY, ABERDEEN; AND ASSISTANT TO THE PROFESSOR OF SURGERY, UNIVERSITY OF ABERDEEN.

MR. PRESIDENT AND GENTLEMEN,—First let me thank you very much indeed for the honour you have done me by asking me to address you to-night. I very much appreciate the task, and although I may fail to do it justice the subject of the address is one of great interest to every medical man at the present time.

For our purpose this evening it is unnecessary to distinguish students from practitioners. The student becomes a qualified practitioner, and every practitioner is, or should be, a student to the end of his days. It is true that after qualification the outlook is different both as regards study and as regards responsibility, but just as there are things which are best learnt while you are unqualified, so there are matters which you will only acquire after you have begun practice. Let me urge you as students and as practitioners never to miss the opportunity of taking this responsibility. Nothing will teach you so much and nothing else will help you so well to learn and appreciate the difficulties of others. Responsibility is a great incentive to progress. It safeguards you from degenerating into mere money-making machines; it prevents you from taking advantage of others who are ignorant of medical things; it urges you to reassure and comfort the needy and suffering; and it brings you that sense of satisfaction and peace which is the one great reward that is your due.

VALUE OF PRACTICAL WORK.

In order to qualify yourselves for this responsibility it is absolutely necessary that you should have educated yourselves properly and should have acquired an accurate, scientific, and logical way of thinking. Moreover, you must be, above everything else, practical, and you will find that when you are confronted with any problem, especially with any sudden emergency, you will at once recall what you have already seen and observed for yourselves. You will as a rule be unable to call to mind what others have said or what this or that book says should be done. Of course, there are a certain number of broad lines of treatment, more particularly in surgery, that are easily learnt and remembered and that change slowly, but, speaking generally, the things that will be useful to you are the things which, as students and house surgeons, you have had the opportunities of seeing and watching. Let me urge you to take careful note of the patient's case and of his name and address, so that you may write to him or to his medical attendant from time to time, and so follow out the course of his disease. Many students leave hospital with an entirely erroneous idea of the natural history and course of disease, especially of malignant disease, because the inoperable and recurrent cases are stowed away in the workhouse. By employing the means I have mentioned you will at once learn a great deal that you would otherwise have missed. More especially will the need for early diagnosis and treatment in the case of malignant disease become apparent.

It is also essential that you should have been on the spot and should have observed for yourselves most, if not all, of the common emergencies of general surgery. Merely to come into a ward in the morning for half an hour and to learn that a patient was operated on during the night for a perforated gastric ulcer is valueless. You could have learnt that in the smoking-room. You should have been on the spot at the time that the patient was admitted, whether during the night or in the daytime, and you should have taken the history of the case accurately and gone thoroughly into the various physical signs which led up to the performance of the operation. The latter is such a very small part of the whole that if you have not actually seen and followed such cases for yourselves you will one day open the abdomen where the patient is suffering from alcoholic gastritis or from lead colic or you will operate for intestinal obstruction on a patient who has been taking diachylon in order to procure abortion. Still worse than this, you will delay operation in certain cases until it is far too late for you to relieve the patient at all. In passing, you should have asked yourselves this question, Could I have dealt with this case in an efficient manner without any assistance? At the present time there is hardly an emergency in general surgery, with the single exception of the surgery of the skull and brain, that you cannot deal with single handed if you lay your plans properly. Naturally, this is not a proceeding that one adopts for choice, but as a matter of necessity it is quite possible at the present day to carry through with success a large abdominal operation single-handed and often with comparative ease. Spinal analgesia when it is a success, is usually an unqualified success, and if by observation and practice you have learnt the fallacies and mistakes that contribute to mar the result you will succeed in the great majority of such cases. Local analgesia has also at the present time been brought to a state which is very near perfection. Automatic retractors can be bought or they can be improvised by means of weights, and, on the whole, if you have thought the matter out and are ready when the call comes you will not meet with any serious difficulty.

Consider the changes that occur in methods of treatment as may be exemplified by the study of appendicitis. Many a life is now saved by an early operation where formerly the patient would probably have died or would, at any rate, have had a long and tedious illness. Many such patients used to die with the symptoms of intestinal obstruction, from abdominal distension, general peritonitis, jaundice, portal pyæmia, subphrenic abscess, and pericarditis, the cause of the later symptoms being often extremely difficult and obscure by reason of the initial onset of the disease having been entirely missed. Study well, then, the natural course of disease, apart from medical and surgical interference, and study also the results of medical and surgical treatment, and compare all these things one with another.

At the present time the great question in surgery is this: "How can I best avoid the operation in my patient's interest, and is this course the right one to pursue?" The popular idea of surgery is one of the knife; diagnosis is entirely left out of account. The public forget that before an operation becomes necessary the question has to be decided as to whether there is any disease amenable to surgical interference present or not, and whether this disease is in the patient's head or his heels. The vomiting and constipation associated with cerebral tumour, or the symptoms of intraperitoneal injury associated with concussion of the brain are common instances, and there are many others. Thus diagnosis will be your first aim. No book will teach it to you but only practical work, and a great deal of that, and very conscientiously carried out. It should be automatic with you to doubt every statement that you hear or read, then you should go and look and see for yourselves and find out whether it is true, or false, or only partially true. Your state of mind should resemble that of the schoolboy who wrote in his examination paper: "We are taught that the natives of these parts used to dwell in caves, but no caves have been discovered and no natives." So many statements are copied from book to book without authority being quoted that theories become stated as facts. In the course of your verification of these matters you will come across many things that are not known, and it is your duty to the profession to stop and if possible investigate and record the issue for the benefit of others. Such opportunities are seldom repeated, and however small the new item may appear to be it should be published because there are always persons on the look out for these things or for confirmatory evidence of older knowledge, and these men will collect your information and place it with that obtained from other sources.

Even if the facts or theories that you publish are wrong they serve the useful purpose of making others think. Such a course sometimes proves to be expensive, but the benefit to the profession is great, and so is the benefit to those who have become sufficiently interested in the matter to stop and investigate it. For instance, at the present time there is great need of a book on the subject of the natural history and course of disease as observed over long periods in general practice. What is required could be written by a practitioner of long experience, but not by one of the younger members of the profession. It is, however, one of the greatest misfortunes that happen to us that hardly anyone sits down towards the end of his life to write out his experiences, facts, and conclusions for the benefit of others. Just at the very time when he is capable of putting these things in a proper light, when his wisdom is far greater than that of any book, at the time of his death this vast store of experimental knowledge perishes with him. There are so many things in medicine that are too long to be settled in a lifetime—it seems to need two or more lifetimes—that until some persons make this an object to be attained we shall be ignorant of much that deeply concerns us. Again and again you see the younger men begin the study of and the accumulation of facts concerning some more special branch of medicine; this leads to greater and greater experience and knowledge, far ahead of that possessed by the average man; the thing becomes a burden to its possessor; and when he retires he either does not care to put it on paper, or he is too much occupied with other things. Sometimes he does not consider it is worth while, and even if he did he would very likely find that it would take many years to touch on more than a few points in the whole. It should, however, be your endeavour, not merely to practise your profession, but to advance it a step or two further.

THE MEDICAL CURRICULUM.

This leads me to mention the obvious fact that all your teaching is very largely specialised. No one at the present time can possibly know all that there is to be known in the subjects of medical science, or about all diseases. Everyone lets some of it go and gives more time to other parts. In this way specialists arise, and the true specialist is the man who, having had a long and varied practical experience of general medicine and surgery, finds that he has been led to see and observe more in a certain limited area of it than in the rest. He is possibly attracted by this or that class of case and he takes to that kind of work more than to any other, and, as a rule, does it better.

Unfortunately, or perhaps fortunately, it is not possible for you to declare at the outset as students what branch you will ultimately take up. Were this possible you would perhaps save a great deal of time in obtaining your qualification, but you would not really gain much, and as matters stand at present you cannot adopt such a course, and it is doubtful if it will ever be possible for you to do so. Nevertheless, certain parts of our knowledge are far more advanced than others, and this results in much disproportion between the various subjects in the medical curriculum. For instance, a general practitioner could probably learn all the anatomy he is ever likely to require in a fortnight if he were properly taught. On the other hand, an aural surgeon can never hope to learn very much in the course of a whole lifetime about the physiology of the ear. All these matters are at sixes and sevens. It is said that the system you are put through teaches you to observe and to think, but it does not seem to occur to anyone that you can be taught to observe just as well, if not better, by employing material for the purpose that will ultimately be of use to you. You are not going to operate on crayfish, neither are you going to be professors of zoology. The question for the teacher should be, "How can I best ensure that at the end of his course the student shall have acquired a practical knowledge of his profession and shall still have some brains left to go on with?" It seems to me that if a student is correctly guided his brain should be at least twice as good at the end of his course as it was at the beginning, whereas sometimes it is undoubtedly twice as bad. It should be able to assimilate what it requires and store it away neatly pigeon-holed for future reference, but instead of that the brain that is left is often literally riddled with holes or sinuses, each one left by an examination. The one that extends between the two ears is a particularly large one. They discharge various facts and débris for a time and eventually become contracted, unimpressionable scars, incapable of further receiving facts or theories, much less of reasoning. The mill, in fact, receives you on an endless band, passes you along, shears off close all the tentacles and feelers and prolongations of your mind, sifts out and throws off as a useless by-product all the original thoughts and speculations that occur to everyone, and turns you out in tabloid form, duly labelled, with a string of letters dragging behind like the tail of a comet, of which the average layman does not know the meaning. But the comet is an abnormal one; the head of it is not as bright as the tail. The system, in fact, forces you to conform to a set standard at peril of being burnt at the stake, and if it does not succeed it labels you "chronic." It prevents you from doing your own work in your own way at the very time when your brain is most receptive. You enter the mill at the age of 8; if you are very lucky indeed you may leave it at 22. For 14 years you have to pass at least three examinations a year, the preparation for which effectually prevents you from educating yourselves in literature, languages, history and arts. During that time you transfer the brains of other people in a scrappy and imperfect manner to notebooks, which once you have used you will take good care never to open again. The substance of the lecture has passed through your head on to paper; it has not remained where it was designed to remain and where you paid for it to be placed; neither has it made you think. If the system were correct it might have done so, but it is incorrect. The chief function of a lecturer is to point out the relative importance of the various parts of a subject, and his power of doing so is much impaired if he has to give lessons in dictation. The system has outgrown itself in all directions; it is incongruous, it no longer teaches you to reason, but merely to pass examinations and to write badly. Incidentally it fills your brains with a smattering of rubbish that is too little to be of use for research and too voluminous to leave room for anything useful. If you come to define the system—not necessarily the medical system only—of so-called modern education you arrive at this statement: "A system that takes money from those who can seldom afford to part with it and gives it to those who sometimes do not deserve it." It should be the duty of everyone in this room to try to improve the present system of general education and of medical education in particular. It is a national duty, and one that we owe to those who come after us. Do not merely get quit of the system and say, "Anyhow, it does not affect me any more and so I will not make any suggestion." This is a sin of omission. To begin and live by it without trying to improve it is worse and is a sin of commission. Many others have to follow, and unless the way is properly paved the nation as a whole will degenerate. Remember the case of the aniline dye industry. The system turns out some good enough men, but a different system would probably turn out many better ones. When you get into the wards you are too old by some three years at least, and you are heartily tired of the whole thing. You do not stay long enough at the clinical part of your work, though you stay as long as you can; and where does your preliminary medical education come in? Is it not true that it proves to be almost entirely useless?

SUGGESTED REMEDIES.

It is true that many of your teachers are teachers by accident and not by design. These men will, as a rule, demonstrate to you things that are of use, and such as they have proved for themselves. They do it at great cost of time and patience, and if it were not that they themselves learn by doing it and are kept up to a high standard by it very likely the system would break down. It is probable that a remedy lies in a combination of the old apprenticeship system with the examination system, the student being apprenticed to his hospital and not to an individual, with two-thirds of the marks given for the apprenticeship and one-third for the examination; but there are objections to this arrangement, and it would be difficult to work. The subjects of preliminary medical education can be materially cut down. For instance, the whole study of biology can be reduced to the description of a single cell to which is added a *résumé* of the principles underlying the different methods of investigation of its structure and functions, and a long and complete demonstration under the microscope of very many different kinds of cells. Pharmacology, too, for your purpose can be greatly cut down, and as to materia medica, not one practitioner in a hundred remembers a tenth part of what he has to acquire for

examination purposes. For actual purposes of treatment or research he can always refer to the known and listed facts if he has been taught the correct use of his books. The manufacturing chemist has taken the place of this part of the older knowledge, and as a matter of business it is far cheaper and safer for you to employ him as part of your system than it is for you to spend your capital and brains in acquiring the minutiæ of such knowledge. After qualification you can always stop and return and verify or look up anything bearing on the subject. The subjects referred to and others that you study are so fascinating that you are apt to spend too long a time at them and to have too little time for clinical work. The weak point in the present system is that the really plodding, conscientious man who tries to learn his work and to get "signed up" as well is often unable to do so; moreover, he is not always the man who scores; the less conscientious but more superficial man sometimes does better. As showing the fallacy of assuming that passing preliminary examinations helps the study of medicine, you will often see men who have taken up the study of medicine late in life simply sail through and turn out well afterwards, and who up to then "did nothing in particular and did it very well."

TEXT-BOOKS.

As to books, the modern text-book is complete and cheap. Consider the vast store of information that has been multiplied quickly by modern printing and illustrative processes. If from such a book you only obtain one really sound idea you have had more than your money's worth; but you will obtain many. The proper use of such a book is as a guide-book. Medical classics are perhaps in a different class. To mention only a few of the more modern ones: Hilton's "Rest and Pain," Foster's "Physiology," Paget's "Lectures on Surgical Pathology," Macready's "Treatise on Ruptures," Clerk Maxwell's "Matter and Motion," Goodeve's "Elements of Mechanism." The system will effectually prevent you from having time to read them, for they do not pay. If ever a treatise did set out in well-expressed logical sequence the facts and theory of a science, that book is Foster's "Physiology," and his "Life of Claude Bernard" is similar. But instead of being given time to read them you are condemned to memorising the absorption bands of blood, tracts in the nervous system that resemble the trains in the "Continental Bradshaw," the names rather than the principles of rare surgical instruments and operations, and a mass of theory stated as fact in a most illogical sequence. Such things are crammed up regularly twice a year, although you always have access to them whenever they are wanted, but just because someone may once have asked a question bearing on them they must be memorised in case they are wanted at the examination. Avoid comparing the exquisite lithographic plates in Macready's "Ruptures" with the present-day photographic reproductions on heavy glazed paper; it is all too sad. Again, by reading the current numbers of the weekly and monthly journals as they appear, you will largely avoid the necessity for reading the more advanced and specialised text-books. You need not pay much attention to the names of the authors so long as you know the substance of the chief papers that deal with common things. But read everything critically, especially the text-book. Such a book may miss out an important point in a subject. For instance, in describing the operation of excision of the upper jaw the danger of fracturing the base of the skull is not mentioned, but I have twice seen it occur. Twice, also, have I seen gross malignant disease left behind in performing this operation in a suitable case, simply because the teacher said the malar bone was not to be removed and the operator had this obsession in his mind. If you study the septum between the maxilla and malar bones you will see what a large amount of harm has resulted from the teaching and practice of a cut-and-dried examination subject without at the same time pointing out its fallacies and limitations in practice. Therefore listen, but do not believe until you have looked for yourselves, and then not always, and certainly never in a hurry.

MEDICAL ETHICS AND OTHER MATTERS.

Now, as practitioners there are certain things that you should know about, certain things that you should have acquired, and certain others that you should do, which the tabloid gentleman has never heard of. They were left out in the scheduled list of the attainments that he should possess. In the first place, secrecy and no gossip. The fact that the patient is consulting you must on no account be known to anyone but the two of you without his consent. You must on on account give any information about any patient, rich or poor, either in hospital or in private practice, without consent. Secondly, you should have a sincere manner totally devoid of pompousness, a manner which has been described as being easy and free without being free and easy. Thirdly, you should know a good deal about the etiquette of your profession. Most of this knowledge is only an application of common sense and good manners, but still, there are certain special points that you should have inquired about, notably the proceeding at consultation. You should do as you would be done by, and never take the bread out of the mouth of another practitioner by underselling him. You should play a straight and honest game, and although I regret to say you will sometimes find that this course is not the one that pays best at the time—for we are all human—there is no doubt that it will do so in the long run. If you cannot cure your patient at least prevent him from falling into the hands of the quack, whose advertisements promise so much to all those who suffer from the things that everybody has got. As a local practitioner said the other day, "I think all medical men should have had a sporting education." Fourthly, on the day you register your qualification you should join a society for medical defence. Self-defence is the first law of nature. Alone you are powerless against the attacks of sundry people, but united you are strong and powerful, for your knowledge is very great and has been acquired laboriously and at great cost. This last fact should always be with you, and it is occasionally useful, as, for instance, when a patient comes to you demanding an explanation of certain symptoms and talking glibly of them. He has read them up in one of the popular "Child's Guide to Knowledge" series, sold by the publishers for the purpose of taking the money. He wastes your time and gives you nothing for it, a proceeding which, if carried on too long, leads to the workhouse. You say to him, "How long can you spare me to tell you this?" He says, "How long do you require." You say, "It took me five years to learn, and it will take at least that." He leaves shortly after. Then, again, you must not be nervous in your practice. You are not likely to be. That you may be very nervous in the totally abnormal mental atmosphere of an examination is nothing. Everyone is, some more so than others, but when you come to practice, if you have succeeded in screwing sufficient time out of the system as you go through it, you will be dealing with matters of which you have already had practical experience, or, at any rate, you will be able to recall a somewhat similar case and you will find that you are really not nervous. For much the same reason things will not frighten you; indeed, sometimes the difficulty will be for you to get sufficiently excited to act quickly. The earthworm and the snail move so slowly, their parts are so intricate, that if you have devoted much attention to them you may possibly still be pondering and thinking, and, indeed, you may be so polarised on them that the flash of the symptoms of angina across the patient's countenance will pass unobserved when you come to see it. Again, you should among other things be able to draw up a will or to take a deposition and see that such is duly executed. Remember, above all things, that the dead cannot speak, and when the speculative insurance agent comes to see if he can avoid his obligation to the widow and children of the dead man, be very careful what you say as to the length of time the patient had been afflicted. In a case of doubt surely the dead should have the benefit of it.

The public are ignorant of medical matters, and it is a good thing that this is the case, because otherwise many of them would become hypochondriacal. The press, however, is teaching the public too much without at the same time warning them that they can never understand medical things without a five years' practical training. A few words in plain language from the patient's point of view will always be acceptable, and if you put the matter clearly you will not have any difficulty and will not be worried when things do not run a rapidly successful course. And never say that there is no risk in an operation, however simple. There is always a risk, but fortunately it is usually a small one. Most distressing incidents occur through neglect of this simple precaution.

Your profession should be taken seriously, though the

humorous side of it will often appeal to you irresistibly. This serves to help you on your way and you will often need it. Another practitioner here remarked lately: "Three things are necessary for a successful practitioner; first, the patience of Job; secondly, the temper of an angel; and thirdly, the power to work miracles." So you see you are likely to need a little fun as well.

PROSPECTS OF SUCCESS.

Then as regards success. In general practice your manner will be the making of you. It has also been facetiously stated that you will make a large practice if you give the mother a clinical thermometer and get on the telephone. You may also succeed by being able to eat a large number of dinners without getting ill. You may even succeed by ability, but this is rare. In whatever way you manage it, do not become mere hurried, money-making machines, devoid of courtesy and observation. You owe more to your profession than that. If you want to make money go into trade; buy carpets from the natives at twopence each and sell them elsewhere at five pounds. It is fairly simple and is also very intellectual, especially if there is competition, but it is not professional, though you will be able to have a holiday whenever you like and you will seldom work more than six hours a day. As medical men you will work all day and most of the night, and will seldom get a holiday.

As practitioners, using the term in the widest sense, we have several advantages. We are at once admitted to any class of society that we like. We carry our profession with us; a certain small stock-in-trade is often necessary, but speaking generally we have only to be in attendance for the matter to be settled. We are nearly certain, if we remain well, to be able to make a living, and we undoubtedly earn the unbounded gratitude of the whole of the civilised world. It would take too long this evening to go into the question of our other privileges. They are well set out in Kipling's address. We are subject to many disadvantages. Our labour is sweated at every turn. In our junior appointments we at least expect in return for giving our labour cheap to have sufficient leisure in which to study and digest the cases that are passing through our hands; it is what we pay for; but in some parts of the country the amount of material passing through the infirmaries has so increased latterly that the junior men are run off their legs with routine work and this reward is denied them. Although the possessors of skill and knowledge, which presumably should be valuable to our employers, our time is wasted in having to enter names in books and files, such work, in fact, as we should give to our children to do at home. In practice we contract a large number of bad debts that we cannot recover without losing our patients, and we are generally the last to be paid. Throughout our lives we have none of the pleasures such as fall to an actor or a statesman. We do not experience the joy of waiting for a fine reception and the plaudits of the crowd. We cannot go on and count our laughs; indeed, they are more usually scored up against us. We are engaged in continually summing-up evidence impartially and trying to steer clear of excess of fashion or of a craze. We become impassive, so much so that sometimes we fail to appreciate the value of the evidence ourselves and become mere mechanical ciphers rather than integral parts of a train of circumstances which we ought to guide intelligently, and when the day's work is finished we may have no interest left unless we have our hobbies. Towards the end of our careers there are only a small number of pensions for us, although as a professional class we are relatively numerous.

And in conclusion, the poet observes with respect to age and health:—

> "God doth not need
> Either man's work or his own gifts; who best
> Bear his mild yoke, they serve him best: his state
> Is kingly; thousands at his bidding speed,
> And post o'er land and ocean without rest;
> They also serve who only stand and wait."

RUSSIAN SURGEON'S CENTENARY.—The centenary of the birth of the famous Russian surgeon, N. I. Pirogoff, was celebrated at the Pirogoff Museum, St. Petersburg, on Nov. 13th (26th) last in the presence of many distinguished members of the surgical and medical professions.

THE TREATMENT OF SPLENIC ANÆMIA BY SPLENECTOMY.[1]

BY G. A. SUTHERLAND, M.D. EDIN., F.R.C.P. LOND.,
PHYSICIAN TO THE HAMPSTEAD AND NORTH-WEST LONDON HOSPITAL, AND TO THE PADDINGTON GREEN CHILDREN'S HOSPITAL;
AND
F. F. BURGHARD, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO KING'S COLLEGE HOSPITAL AND TO THE PADDINGTON GREEN CHILDREN'S HOSPITAL.

SPLENIC anæmia or primary splenomegaly is a disease almost always, if not invariably, fatal, whatever the medical treatment may be. The pathology is not yet clearly determined, and reliance on the diagnosis must be placed at present on certain clinical features which are fairly clearly defined. In former years the term splenic anæmia has been loosely applied to other disorders of the blood and other diseases of the spleen, as is clearly shown in many recorded cases. But if surgical treatment is to be adopted it is of the greatest importance to have the disease clearly defined, as otherwise disastrous results may follow and the operation be unjustly condemned.

Professor Osler[2] has done much in differentiating the characteristics of splenic anæmia, and Dr. H. D. Rolleston[3] has summarised them as follows: 1. Anæmia of the type usually spoken of as chlorotic—i.e., a diminution in the number of red corpuscles, with a diminished corpuscular value in the hæmoglobin. 2. Absence of any leucocytosis, usually leucopenia. 3. Considerable splenic enlargement, which cannot be correlated with any other known cause, such as leukæmia, syphilis, tuberculosis, malaria, or hepatic cirrhosis. 4. The prolonged nature of the disease. 5. The tendency to gastro-intestinal hæmorrhage from time to time. 6. The termination of the disease, if sufficiently prolonged, in hepatic cirrhosis with ascites (Banti's disease).

The last three of the above criteria may be described as accidental and non-essential. While Osler and Irving Lyon lay stress on the prolonged course of the disease, Frederick Taylor and Samuel West emphasise the fact that death usually occurs in from six months to four years. As a matter of fact, there would appear to be acute or subacute cases and chronic cases, the latter of which may last from 10 to 20 years. It may be that the juvenile type of disease tends to run a more acute course than that met with in adult life, as so often happens in the case of other affections. Certainly in the two cases to be related it was the steady progress of the patients downhill which led to the adoption of surgical treatment. Another of the points noted above—namely, the occurrence of hæmatemesis—does not appear to be so common in children as in adults, but Osler has recorded one instance. The termination of splenic anæmia in Banti's disease, hepatic cirrhosis with ascites, seems open to question, at least as regards the majority of cases, and Osler and Senator have pointed out that ascites may occur as a terminal event in anæmia without any hepatic cirrhosis.

The first three of the above criteria give the essential features of the disease. It will be noted that they rather exclude other diseases than indicate any special characteristics of splenic anæmia. In addition the appearance of the patient is very striking, the profound pallor, with a creamy tinge in the skin generally. We hope it may be possible to add a fourth criterion of the disease, at least in the case of children—namely, the rapid disappearance of all symptoms after splenectomy. Further experience of the results of operative treatment must be obtained before this can be done. The treatment by splenectomy is not new. Armstrong[4] has collected from the literature 32 cases of splenectomy for splenic anæmia, with 23 recoveries and 9 deaths. At the same time, it must be noted that many cases are included in which the diagnosis is by no means clear. The operation has rarely been performed in this country. In the Transactions of the Clinical Society of London there is only one case of splenectomy for disease recorded; the disease was leukæmia and the result fatal. It

is clear also from the recorded cases that too often splenectomy was performed as a last chance, when the disease had lasted for many years and when a successful result could scarcely be expected.

CASE 1.—The patient, a girl aged 12 years, was admitted to hospital on April 24th, 1906, suffering from rheumatism. For the previous two years she had been languid and complaining of pains in the extremities. At times the knee and other joints had been swollen and painful. No abdominal swelling had been noted previously to admission. The parents were healthy and there were five other children—all boys—alive and healthy. Four children had died—all girls—three of them when quite young, and the fourth from splenic anæmia at the age of 13 years. Her case has been published by Dr. Frederick Taylor in the Guy's Hospital Reports for 1895, under the title "A Case of Splenic Anæmia or Primary Splenomegaly."

On admission the patient was well nourished but distinctly anæmic, the skin having a pale yellow tint all over, and the lips having little colour. The conjunctivæ were not jaundiced. There was a deeper pigmentation, of a brown colour, at some pressure areas—e.g., above the knees where the garters had been worn. The left side of the abdomen was occupied by a large solid mass, evidently an enlarged spleen, which measured 8 inches in its longest diameter, as tested by percussion and palpation. There was no pain or tenderness about this swelling, which was freely moveable in all directions The liver was not enlarged and there was no bile in the urine. The heart was slightly enlarged and a soft systolic murmur was present at the apex, considered valvular in origin. Apart from the subacute rheumatism from which she was then suffering there was no evidence of constitutional disease, such as syphilis, tuberculosis, or malaria. There were no hæmorrhages and no enlarged lymphatic glands. The result of examination of the urinary system and of the fundus oculi was negative. The temperature at times reached 100° F. in the evening, but there were no definite pyrexial attacks. On admission the red blood corpuscles were 2,420,000, the hæmoglobin being 56 per cent., and the white blood corpuscles numbering 9800. A differential count of the white cells showed nothing abnormal. The results of the various blood examinations are seen in the accompanying chart. (Fig. 1.) It will be noted that on May 30th there is a condition of leucopenia, as is common in this affection, but the coexistence of subacute rheumatism may at other times have kept up the number of white cells, although a definite leucocytosis did not occur until after the operation. Treatment was carried out by means of arsenic, iron, X rays (three sittings), and full diet, and later the patient was sent to the convalescent home.

On readmission at the end of June the patient was distinctly more anæmic, and both red cells and the hæmoglobin were found to be diminished. After consultation it was decided to excise the spleen, and this was done on July 20th. The spleen with the contained blood weighed 2 pounds, and showed general hyperplasia of all the tissues. There was no marked shock after the operation, and when the effects of the anæsthetic had passed off the patient made a rapid recovery. Three days after the operation it was found that the red cells had increased from 2,500,000 to 4,700,000, and the hæmoglobin from 40 per cent. to 76 per cent., an improvement which was maintained until at the end of another week the red cells were normal in number. This alteration was also visible in the appearance of the child; the yellow tinge of the skin had gone, the cheeks were pink in colour, and the lips were taking on a healthy red hue. There was no compensatory enlargement of the lymphatic glands.

The further history of the case as regards symptoms of splenic anæmia is negative. A condition of subacute rheumatism continued for two years, during which mitral stenosis developed, and an attack of chorea occurred. She was seen again in November, 1910, at the age of 17½ years, and four years after the operation. She was then a well-grown girl in service as a nursemaid. The cardiac lesion persisted, but there had not been any symptoms of active rheumatism for two years. There were no marked signs of anæmia in her appearance. Blood examination showed red blood corpuscles 3,600,000, hæmoglobin 78 per cent., and white blood corpuscles 6400. The girl expressed herself as feeling quite well and able for her work.

CASE 2.—The patient, a girl aged 6 years, was sent to hospital on April 7th, 1910, by Mr. W. M. Noott of Kensington, with a diagnosis of anæmia and enlarged spleen. The mother stated that the child had been pale since birth, and that this pallor had not increased recently. She had been short of breath on exertion for some time. Two months previously she had had a feverish attack, with pain in the splenic region, and Mr. Noott had then discovered the enlarged spleen. There had never been purpura or any form of hæmorrhage. Her previous health had been good, and she had not suffered from any other form of illness. The family history was unimportant and revealed no other case of splenic disease.

On admission the child was found to be well nourished and of healthy appearance apart from the anæmia. The skin of the face was pale, of a creamy tint, with a faint pink flush on the cheeks. The lips, eyelids, and gums were pale. The yellowish tinge of the face was seen also in the conjunctivæ, and in the skin generally. There was no deeper staining over pressure points. Some of the cervical glands were slightly enlarged, but there was no evidence of any general glandular enlargement. A large solid mass was felt in the left side of the abdomen which was evidently an enlarged spleen. It extended downwards a finger's breadth beyond the umbilicus, and its longest diameter measured six inches. The spleen was freely moveable and not tender or painful. The liver was not enlarged and there was no bile in the urine. Examination of the blood showed red blood corpuscles 2,550,000, white blood corpuscles 6300, and hæmoglobin 34 per cent. No increased bleeding occurred on pricking for the blood examination. There was no evidence of disease in the cardiac, pulmonary, or renal systems. The fundus oculi showed no abnormalities. Von Pirquet's test and the Wassermann reaction were negative. The temperature usually rose to 100° F. at night, falling to normal in the morning. Epistaxis occurred once during her stay in hospital. The treatment was rest in bed, full diet, arsenic, and iron. After a fortnight in the hospital the patient developed measles and was sent home. During the summer she spent some weeks at the convalescent home and her colour improved considerably. The spleen varied in size from time to time, but only to a slight degree.

The patient was readmitted to the hospital on Oct. 8th, 1910. The only changes to be noted were the increasing pallor, listlessness, and tiredness. Examination of the blood on Oct. 10th gave the following result:—Red blood corpuscles, 1,870,000; hæmoglobin, 30 per cent.; white blood corpuscles, 2400; and colour index, 0·8. The red corpuscles were very various in size, megalocytes, microcytes, and all intermediate gradations being present. There was a little polychromatophilia in some of the corpuscles, but it was not marked, and there was no punctate basophilia. The red cells were normally shaped, poikilocytosis being absent. Nucleated red cells, all normoblasts, were present to the extent of about 600 per cubic millimetre. Amongst the white cells there were large hyalines (0·4 per cent.), myelocytes (1·2 per cent.), and mast cells (1·2 per cent.). After consultation it was decided to excise the spleen and this was done on Oct. 17th. The patient stood the operation well, there was no marked shock, and after the effects of the anæsthetic had passed off she had no untoward symptoms of any kind. The temperature continued normal after the third day. On removal the spleen showed no gross changes save its great size and congested appearance; it weighed one pound. As regards the histological changes, Dr. W. d'Este Emery found no very marked abnormalities of structure save the general hyperplasia. On Oct. 21st—four days after the operation—it was noted that the patient's colour had decidedly improved, that the lips were redder in colour, and that the yellow tint of the conjunctivæ and skin had gone. Examination of the blood on the same day confirmed these signs of improvement. A blood count gave red blood corpuscles 4,000,000, hæmoglobin 52 per cent., white blood corpuscles 10,800, and colour index 0·6. There were no abnormal red corpuscles, nucleated or degenerated forms, seen, and no abnormal leucocytes. The child improved daily, and the languor and listlessness which had been present all through the illness passed off. There was no compensatory enlargement of the lymphatic glands. On the seventeenth day after the operation the red corpuscles were 5,200,000, the white corpuscles 3400, and the hæmoglobin

was 65 per cent. The patient is at present—seven weeks after the operation—at the convalescent home, and is doing well.

The operation.—The steps of the operation call for little remark. In both cases the incision was made through the left rectus parallel and just internal to the left linea semilunaris. In the first the spleen was so much enlarged that its undue mobility allowed it to be dislocated into the wound and outside the abdomen with great ease. In the second case the mobility of the organ was not so marked, and the only difficulty experienced in the operation was to dislocate the spleen without injuring it. In order to accomplish this satisfactorily the outer edge of the incision had to be depressed forcibly with large retractors.

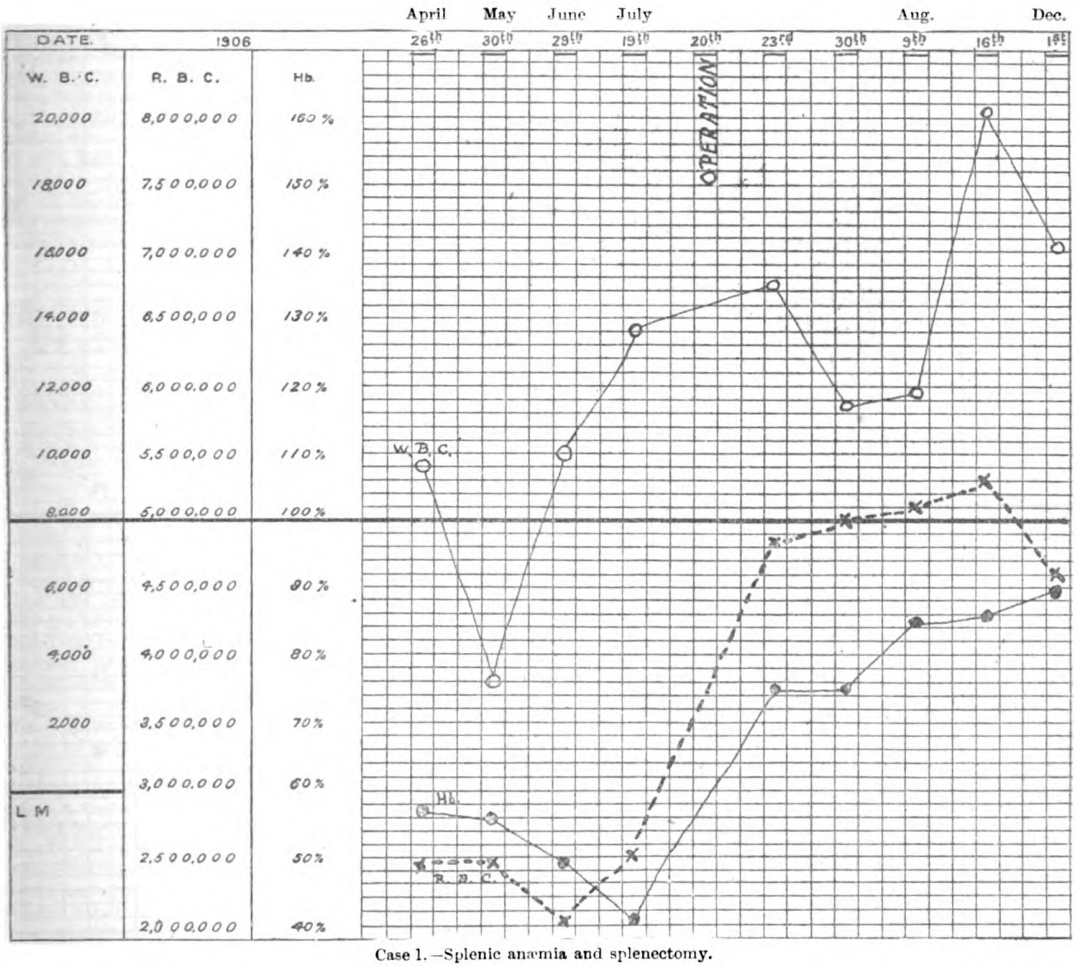
In neither case were there any adhesions between the capsule of the spleen and the abdominal wall, and the question of hæmorrhage never caused the least anxiety. The only bleeding was from the abdominal incision, and care was taken to reduce this to a minimum by clamping every bleeding point as it was met with. The actual removal of the spleen was done methodically as follows. When the spleen had been protruded through the wound, cautious traction was exerted so as to put upon the stretch the gastro-splenic omentum running from the hilum of the spleen to the fundus of the stomach. The anterior layer of this was then divided separately between pressure forceps, three pairs being used on each side of the line of division. This exposed the left gastro-epiploic artery and the vasa brevia lying in front of the posterior layer of the ligament. These vessels were pushed aside, while the smaller vessels were controlled at their entrance into the hilum by a large clamp forceps and the posterior layer of the omentum was then taken up in sections quite close to the fundus of the stomach by three pairs of pressure forceps and divided with scissors between the forceps and the clamp. This severance of the gastro-splenic omentum allowed the spleen to be rotated still further outwards, and pulled up into easy reach the lieno-renal ligament with the splenic artery and vein between its layers. This traction proved very useful as it converted this structure into a true ligament, so that it was easy to transfix it with one blade of the pressure forceps where it was clear of vessels. A large clamp was put on near the hilum, and the ligament and the vessels were then secured by two pairs of pressure forceps about half an inch nearer the spine, and the tissues were then divided between and the spleen removed.

An interesting practical point developed in connexion with the ligature of the vessels. In the first case no ligatures were applied until the spleen had been removed. It was then found that the forceps on the splenic vessels and the lieno-renal ligament at once retracted deeply into the abdomen under the vault of the diaphragm, and great difficulty was experienced in tying the ligatures owing to the cramped space in which the hands had to work. In the second case, therefore, each ligature was applied and tied immediately the forceps were freed by dividing the tissues upon which they were placed, and in this way no difficulty was experienced in securing every vessel as it was divided. The ligatures were of medium-sized chromic catgut and it was not judged necessary to reinforce them by a surrounding ligature.

The entire operation was done in a very short time and at no time was any shock apparent. The abdomen was closed in three layers in the usual way.

In this paper we are concerned with the pathology of splenic anæmia only so far as it relates to the question of

FIG. 1.



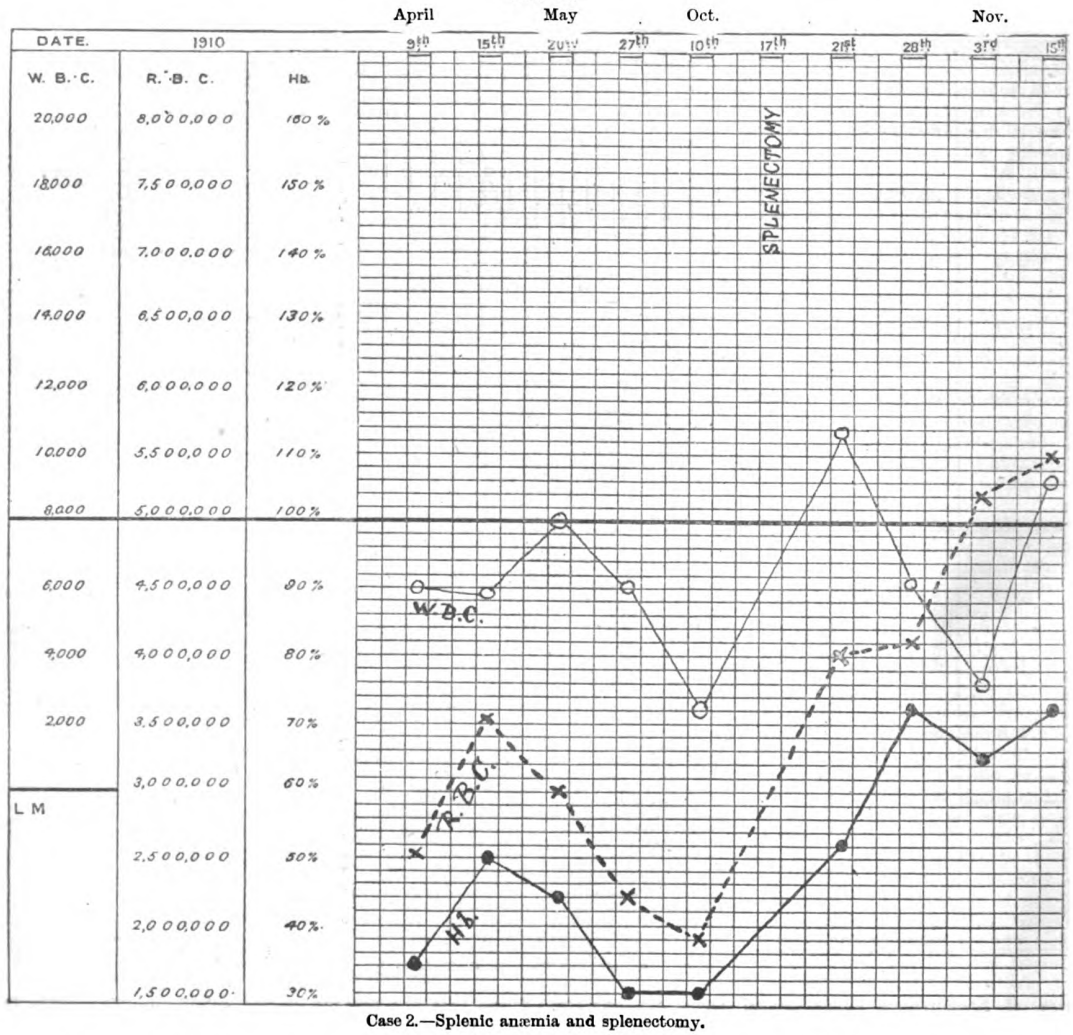
Case 1.—Splenic anæmia and splenectomy.

surgical treatment. There is no direct evidence of primary disease in any other tissue of the body than the spleen, and if a constitutional disease like malaria is present the case cannot be regarded as one of primary splenomegaly. Rolleston has suggested that "a chronic infective or toxic process has its headquarters in the spleen, and that the poisons produced there give rise in the first instance to endothelial hyperplasia and fibrosis of that organ, and later so inhibit blood formation as to produce anæmia of the type usually regarded as chlorotic." Our experience does not support the view that there is an inhibition of blood formation. We believe that the spleen is actively engaged in the destruction of blood cells. The yellowish tinge in the skin and in the conjunctivæ is probably due to active hæmolysis in the spleen—it is certainly not due to any disturbance of the liver function. The condition after splenectomy supports this view. The pigmentation of the skin and conjunctivæ disappears within a week, and at the same time the number of red cells and the amount of hæmoglobin increase with astonishing rapidity. If there had been inhibition of blood formation we should not have expected such a rapid return to normal, but if the blood-forming organs had been working at high pressure to make up for the destruction of red cells this rapid recovery, when hæmolysis had ceased, is exactly what would have been expected. In connexion with Case 2 it will be noted that the abnormal and degenerated red blood cells which were present before operation had entirely disappeared at the time of the first blood count after the operation. This also points to a condition of active hæmolysis in splenic anæmia, which ceases with the removal of the spleen.

The examination of the spleen, post mortem and after excision, has been most elaborately carried out, more especially by American investigators, and has failed to reveal any clear evidence as to the nature of the disease. The tendency has, therefore, been to fall back on some theory of toxæmia due to the changes in the spleen. Yet the toxæmic result may be described as an exaggeration of what is usually considered the normal function of the spleen—namely, the removal or destruction of red cells.

On the other hand, if we assume a loss of vaso-motor control in the splenic artery leading to overfilling of the spleen with arterial blood, it is possible to understand all the morbid changes in the spleen and in the blood. The spleen itself would be enlarged and its substance generally, Malpighian corpuscles, endothelial cells, connective tissue, &c., would be in a state of active hyperplasia. This is the usual condition found after splenectomy or post mortem, with the added changes which time has brought in prolonged cases. At the same time, the functional activity of the spleen would be increased, and the function which is usually ascribed to it is that of removing red corpuscles by means of its large endothelial cells. Instead of mere scavenging work it is easy to understand that these endothelial cells, in greatly increased numbers, may attack not only effete cells but those which are healthy, and that active hæmolysis and destruction of hæmoglobin follow. The hæmatemesis which is such a striking feature in many of the cases will be easily explained on the same assumption—i.e., that the arterial blood sent to the stomach through the splenic artery is excessive in amount, and over-distension and rupture of the stomach vessels result. An analogous condition is seen in the case of

FIG. 2.



Case 2.—Splenic anæmia and splenectomy.

the thyroid gland in Graves's disease. The thyroid is distended with blood, its tissues are in a state of hyperplasia, and its normal secretion is poured out in increased and toxic amount. We do not wish to press the analogy, but to emphasise the point that a disease of the thyroid is not assumed to be present in Graves's disease, but only a disturbance of function, and that similarly a disease is not necessarily present in the spleen in splenic anæmia, but simply a disturbance of function. If this be accepted, and if it be recognised that this disturbance of function will usually have a fatal termination, the operation of splenectomy will be fully justified and will probably be more extensively carried out in the future than it has been in the past.

As regards the ultimate result of the operation we can only give particulars in one case, the other having been so recently operated on. The first patient when seen at the age of 17½ years, four years after the operation, was a healthy girl without any signs of splenic anæmia. This result may be contrasted with the fate of her sister, who died at the age of 13 years from progressive anæmia and debility. In the published cases of this disease in which the spleen was successfully removed the ultimate result seems to have been a complete cure, records having been obtained up to eight years after operation. It is probable that the two factors present in our cases, the youth of the patient and the comparatively early stage of the affection, were of importance from the point of view of prognosis. While a preliminary course of medical treatment will naturally be adopted in all cases of splenic anæmia, experience has shown that it is never curative, and if the diagnosis is clear treatment by splenectomy should not be unduly delayed.

THE SURGICAL TREATMENT OF CANCER OF THE VULVA AND ITS PRE-CANCEROUS STAGES.

BY FREDERICK J. McCANN, M.D. EDIN., F.R.C.S. ENG.,

PHYSICIAN TO IN-PATIENTS AT THE SAMARITAN FREE HOSPITAL FOR WOMEN MARYLEBONE ROAD, N.W.; LECTURER ON GYNÆCOLOGY, MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, CHENIES STREET, W.C.

IT is a matter of common knowledge that the ultimate results of operations for vulvar carcinoma hitherto published are unsatisfactory, both local recurrence and recurrence in the inguinal and iliac glands being frequently observed. I believe the unsatisfactory results are due to the operations which are advised and practised for this disease either being incomplete or only employed when the disease is already advanced. Improved results will be obtained by the employment of a complete operation in the early stages of the disease. A nodule or a suspicious ulcer on a labium is not difficult to recognise, but what is of greater importance is to recognise and to treat the precancerous stages. Leucoplakial patches occur on the labia and precede the development of cancer, bearing a similar relationship to the disease in this situation as they do to cancer of the tongue. They are also commonly associated with a labial carcinoma, and it is absolutely necessary that they should be freely excised, for recurrence will certainly take place where such patches are situated. This important fact was impressed on my mind some years ago when doing the incomplete operation generally advised. I had removed the growth with a margin of healthy tissue from one labium, and at the operation I observed a white patch of about the size of a sixpence situated on the opposite labium. This was not removed, and 12 months later the patient returned with a cancerous growth which had appeared in the situation occupied by the leucoplakial patch.

Cancer of the vulva is essentially a disease of elderly women from 55 years of age onwards. When it attacks the labia there is frequently a history of pruritus which has existed for months or even two or three years. The skin of the vulva is white, sodden like the hands of a washerwoman, and numerous cracks or fissures are distributed over its surface. The pruritus continues, is aggravated by scratching, and later a cancerous growth makes its appearance. This sodden skin constitutes the precancerous stage, and when recognised in elderly women should be treated by free excision.[1] Well-marked leucoplakia is seen in younger women in association with syphilitic elephantiasis, and here, too, complete excision is indicated.

A further argument in favour of a more thorough excision is the frequency with which contact infection is observed in the labia, so that when one labium is affected it is not sufficient to do a limited operation, for the surface with which the growth has been in contact on the opposite side may have already been infected.

In every case, however early the disease, the vulva should be completely excised and the glands and fat removed from both inguinal regions. The operation is commenced by removing the inguinal glands. For this purpose an incision is made parallel with Poupart's ligament from the anterior superior iliac spine into the labium (see Fig. 1, B). Poupart's

FIG. 1.

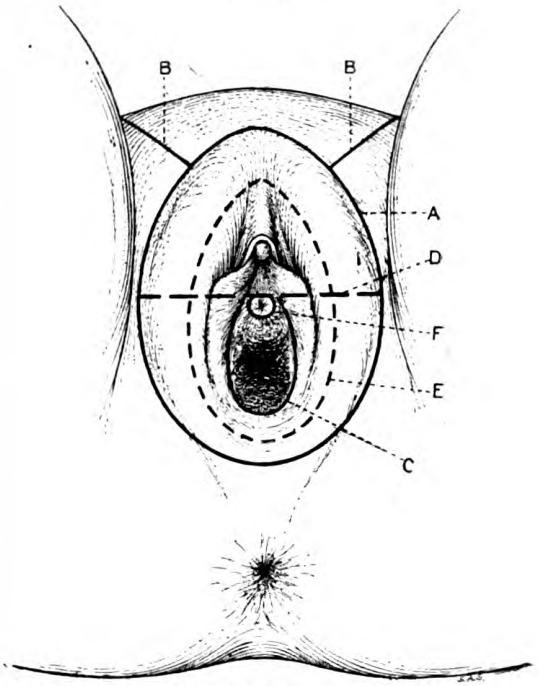


Diagram to illustrate the lines of incision described in the text. A, Incision employed for the removal of the vulva. B, Incision for the removal of the inguinal glands. C, Incision around the vulvar inlet. D, Incision required when the vulva is removed in two portions. E, Incision required for the treatment of severe pruritus. F, Incision around the urethral orifice.

ligament is defined and the glands and fat removed in one piece. Special care is taken to remove the fat and lymphatics at the inner part of the incision (B, Fig. 1). It is necessary to excise the gland in the saphenous opening, and may be others of the vertical set of glands. The gland in the saphenous opening, although it belongs to the vertical chain of glands, is frequently infected with cancer. The gland in the crural canal should also be removed, care being taken not to injure the femoral vessels.

In advanced cases the glands along the iliac vessels are involved in the disease and they can be removed after careful separation of the peritoneum by an incision corresponding to the middle third of Poupart's ligament made through the abdominal wall. Unfortunately, many of the patients are very old and not infrequently suffer from chronic bronchitis, and for these reasons do not stand an operation unduly prolonged. If, however, the patient's condition will stand it the iliac glands should certainly be removed. All hæmorrhage should be carefully arrested, and before stitching the skin all dead spaces should be obliterated by catgut sutures. The skin is then accurately sutured and a dressing applied.

It is sometimes stated that if the inguinal glands are not felt to be enlarged it is not necessary to remove them. If the inguinal glands are *not* enlarged there is greater reason for removing them, for it may indicate early implication and a better prognosis. If the inguinal glands are enlarged to any extent the iliac glands will also be involved and the

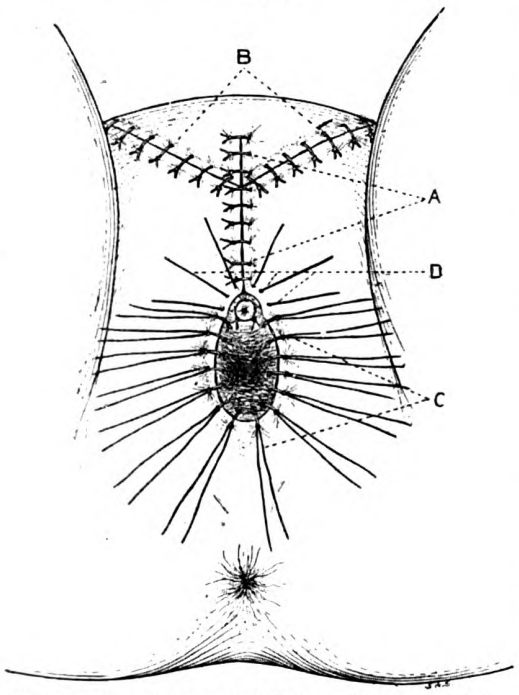
[1] Clinical Journal, Polyclinic Journal, Nov. 15th, 1905, p. 78.

prognosis is bad. I have removed inguinal glands no bigger than a pea which showed under the microscope well-marked cancerous invasion. Moreover, there is considerable difficulty in palpating the inguinal glands when the patient is fat, and many women who suffer from vulvar cancer have a tendency to obesity. *Inability to palpate the inguinal glands is no reason for neglecting to remove them, nor is it a reason for concluding that they are not invaded by the disease.*

When the inguinal glands and fat have been excised on both sides the patient is placed in the lithotomy position and the excision of the vulva is commenced. With a scalpel a curved incision is made on either side from the mons veneris downwards and outwards, terminating at a point midway between the anus and the vulvar inlet (Fig. 1, A). These incisions must be carried well beyond the labia majora. The incisions are deepened by snipping with the scissors, and the bleeding points are caught with Spencer Wells forceps. If the incisions are not made *into the labia* the vascular bulb is not cut into and therefore the amount of bleeding is lessened; a result which is aided by using scissors instead of a knife. Indeed, the amount of hæmorrhage during the whole operation should be comparatively trifling.

All the structures are removed down to the triangular ligament and the clitoris is divided. At this stage it is well to make a circular incision around the urethral orifice (Fig. 1, F) so as to define its position should the cancer be close to the urethral orifice, or a transverse incision may be made above the level of the meatus (Fig. 1, D) when the cancer involves the clitoris, and the vulva is then removed in two portions. In this way the urethra can be seen and avoided, and it is not necessary to pass a sound into the bladder as a guide. During all the manipulations the cancer should be covered with iodoform gauze and the two cut edges of the vulva grasped with a vulsellum to minimise the risk of cancer infection.

FIG. 2.



Illustrates the appearance when the operation is completed. A, Skin incision united. B, Incisions for removing the inguinal glands. C, Silkworm-gut sutures tied and left long to facilitate subsequent removal. D, Mattress sutures of catgut for fixing the meatus. They are represented untied.

After the structures have been freed all round a circular incision made around the vaginal orifice completes the excision (Fig 1, C). The bleeding points are now tied, and in so doing a needle armed with catgut is of service owing to the tendency there is for the vessels to retract in certain situations. Where the clitoris has been divided the hæmorrhage is best arrested by the passage of a mattress suture to embrace the divided vessels. All bleeding having been completely arrested, the edges of the incisions are now united by silkworm-gut sutures.

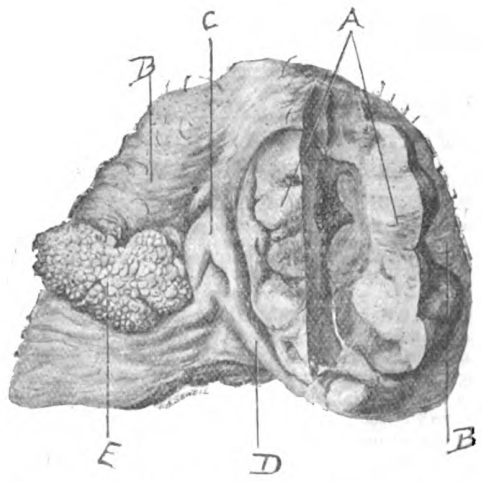
The urethra is fixed in position by lateral mattress sutures of catgut which pass through the sides of the urethra close to the meatus, and a median suture passing through the superior wall (Fig. 2, D). These sutures prevent the urethra falling downwards and tend to maintain the normal forward curve. Where it is found necessary to excise a portion of the urethra the cut end should be divided longitudinally and transversely and the four segments united to the skin edges with catgut.

The silkworm-gut sutures around the vaginal orifice should be left long as there is a tendency for the line of incision in this situation to be retracted towards the vagina, and the long threads facilitate removal. There should be no tension on the sutures if the skin edges have been judiciously undercut.

The wound is dressed with iodoform gauze, wool, and a T bandage. The inguinal wounds are redressed and a double spica domette bandage carefully applied.

I have now performed this operation ten times. In eight of the cases the cancer originated in the labium and two in the clitoris. All were microscopically squamous carcinomata. The healing was rapid and in no case was the use of the catheter subsequently required, the patients being encouraged to pass urine naturally.

FIG. 3.



A, Growth in left labium majus. It has been divided in the centre and the two halves pulled asunder to show how it is penetrating into the subjacent tissues. Note also the ulcerated surface. B, The skin of the mons veneris and labia majora. C, The clitoris. D, The left labium minus. E, The papilloma.

The routine employment of a more extensive operation in the treatment of this disease will, I feel sure, lead to much better results in the future. No operation should be considered sufficient which does not include the removal of the entire vulva and the glands and fat in both groins. The earlier such an operation is employed the better will be the after-results.

To excise the thickened white sodden skin associated with pruritus it is not necessary to cut so widely, but every portion so affected should be removed, otherwise the pruritus will not be cured and cancer may subsequently develop on the thickened areas left behind. When the region of the clitoris is involved this organ should also be removed.

This operation will be found a most valuable remedy for cases of intractable pruritus, and in elderly women in whom the peculiar changes in the skin have already occurred it may be the means of preventing the development of carcinoma. What I desire to advocate here must not be confounded with what is known as the Marion Sims operation, in which a very limited amount of tissue is removed around the vulvar inlet and which is recommended for cases of pruritus. In my operation a complete excision of all the sodden skin, including the clitoris if involved, is

done, so that every trace of disease is removed. The hæmorrhage is carefully arrested, and the wound edges then united with silkworm-gut sutures.

I believe this operation to be of great value, and if done more frequently would prevent the subsequent development of carcinoma. The great frequency with which long-continued pruritus antedates the development of vulvar carcinoma seems to have been overlooked, and when it occurs in an elderly woman prompt and radical treatment is required.

Fig. 3 represents the anterior portions of the labia majora with the clitoris and adjoining parts of the labia minora. The left labium majus is the seat of an extensive ulcerating carcinomatous growth which has invaded the entire thickness of the corium as far as the subjacent fat. Histologically the growth is a squamous-celled carcinoma, the cell columns of which show typical cell nests and central keratinisation. On the opposite labium majus there is a second growth about one inch in diameter which overlaps its base of attachment and presents an intact papillary surface beneath which the corium is uninvaded. Microscopically it is a papilloma. The specimen is preserved in the Museum of the Royal College of Surgeons of England (4690 c). The parts were excised by me from a woman, aged 69 years, who for six months had noticed a growth on the labium, from which there was a slight blood-stained discharge. She had previously suffered from pruritus, and the skin of the vulva presented a thickened whitish appearance. The patient could not say which of the two growths appeared first. With the vulva the glands in both groins were excised.

Wimpole-street, W.

THE VALUE OF VACCINATION AND REVACCINATION.

BY F. M. SANDWITH, M.D. DURH., F.R.C.P. LOND.,
GRESHAM PROFESSOR OF PHYSIC.

FOR more than a hundred years we have known how to prevent small-pox, a repulsive disease of great antiquity, which used to be a common scourge, and at the end of the eighteenth century was the cause of 1817 deaths every year in London alone.

Nearly twenty years elapsed between the time when Edward Jenner began to ponder over the connexion between vaccinia and variola and the day when he announced to an incredulous world "that the cow-pox protects the human constitution from the infection of small-pox." Like Bacon, Harvey, Newton, and Darwin, he preferred to delay the publication of a new truth for which he felt the world was hardly prepared. Before his famous *Inquiry* was published in 1798, Jenner travelled from Berkeley to London in order to exhibit the cow-pox to his professional brethren and prove to them that an individual who had been accidentally or purposely inoculated with vaccinia was rendered immune to subsequent inoculations of variola. We can imagine the cruel disappointment of the country practitioner when, at the end of three months, he was obliged to return home without having persuaded a single individual to be vaccinated! The medical profession was temporarily blind, while the public clung to the conservative belief that it was better to be inoculated with small-pox, with its preliminary horrors of bleeding, purging, and starving, than to test a novel method of prevention. The tide of opinion, however, shortly turned, and vaccine was carried to so many foreign countries that within ten years of its introduction upwards of 20,000,000 people were vaccinated, with the result of an immense reduction of the death-rate from small-pox. Yet in England, and especially in London, the opposition continued inexplicably. Hideous prints and scurrilous newspapers were published, and in 1807, when Parliament awarded Jenner a second grant of £10,000, a popular leader sent a messenger to his lodgings to advise him "immediately to quit London, for there is no knowing what an enraged populace may do."

Times have changed, but we still have amongst us an energetic body of antivaccinators, some of whom might be the lineal descendants of those who could not see that Jenner was a benefactor to mankind. The trend of modern legislation has invariably been to grant concessions to these agitators, and the Vaccination Act of 1907, which came into force on the first day of 1908, has been associated with an increase in the percentage of exemptions of children, in whose case a statutory declaration has been obtained. The figures for 1907, which are the latest published, show that only 70·9 per cent. of children born in England and Wales were vaccinated, a considerable reduction from 74·9, which was the average of the preceding five years. The percentage of children born who were exempted under certificates of conscientious objection has been increased from 4·8 in 1905 to 5·8 in 1906 and 8·4 in 1907, while it is believed that the figures for 1908 will show a further increase.

We must face the fact that we have among us an increasing number of persons who are susceptible to small-pox in consequence of the neglect of vaccination, and that the only other factor necessary to produce an epidemic is the introduction of the disease. We are unable to prophesy when the next outbreak will occur, but, as regards London, we can guess that, if history repeats itself, the day is not far distant when crowds of frightened people will be clamouring for revaccination, as they did when small-pox was last prevalent in 1902. The latest report of the Metropolitan Asylums Board tells us that during the 38 years of the existence of that Board 72,691 small-pox patients have been admitted to its hospitals, but statistics show that, whereas during the first 15 years of the Board's life London was visited by small-pox every third or fourth year, during the last 23 years these outbreaks have only occurred every seventh or eighth year. Moreover, it is satisfactory to know that for the third year in succession not a single death from small-pox has occurred in London. Besides a diminution of the visitation of variola there seems to have been a feebler intensity of the virus of late years in this country.

During 1908 small-pox occurred in 13 towns in England and Wales, the greatest number of cases being reported from Liverpool and Southampton, and in nearly every instance the infection appears to have been introduced from foreign countries. Six cases were notified from London and several in other towns during the first quarter of 1909. At Bristol a limited but somewhat severe outbreak occurred, causing 35 cases and 9 deaths, while in the neighbouring districts there were 22 additional cases with 3 deaths. The infection was introduced from abroad and was spread to some extent by the non-recognition of early cases until warning notices had been issued to local practitioners. Every year that small-pox becomes more rare there must be an increasing number of young medical men who have no real working knowledge of the disease, and in some recent outbreaks there has been a greater tendency than usual to confuse cases of mild small-pox with chicken-pox. On the other hand, in 1908 six persons in London certified to have small-pox were found on examination by an expert to be suffering from chicken-pox. The more unusual the disease, the more errors in diagnosis must occur. The failure to recognise a hæmorrhagic case at Bristol led to the second introduction of small-pox into a general hospital. The sanitary methods of fighting this Bristol outbreak may be taken as typical of what ought to be done under similar circumstances. All known contacts were immediately vaccinated or revaccinated, each patient being thus promptly surrounded by a circle of protected friends and relatives; all neighbours willing to undergo protection were revaccinated; every suspected case was at once isolated; contacts were traced and watched so effectually that 16,396 visits were paid to 1354 persons. If we cannot obtain complete protection by vaccination and necessary revaccination, we must perforce be content, directly a case of small-pox is discovered, with the intelligent coöperation of the sanitary authority and the board of guardians. The duty of the former is to isolate the sick and to supervise contacts, while the latter should at once vaccinate all known contacts and as many others in the district as are unprotected. The Bristol board of guardians refused to provide special facilities for vaccination, and furnished an additional argument for the transference of vaccination work from the control of the guardians to that of the sanitary authority, as recommended by the Poor law Commission. However, the necessary vaccination in Bristol was secured in spite of the unwillingness of the guardians to take special measures.

The comparative mildness of recent outbreaks in the United Kingdom is no guarantee that future epidemics will not be severe, though this is one of the points which antivaccinators fail to understand. Neither are they convinced by the

accumulated evidence of the immunity of efficiently revaccinated doctors and nurses in small-pox hospitals, facts which cannot too often be repeated to the public, not forgetting the exceptions to this immunity provided by nurses or other employees who have declined or evaded revaccination. Any fair-minded person should appreciate the lesson furnished by the nursing staff in 1892–93 at Leicester, where disbelief in vaccination is rampant. Among 40 nurses six refused to be vaccinated; one of these six caught small-pox and died from it, while four others contracted the disease and recovered. The sixth disbeliever, who escaped infection, was the matron, whose relations with the small-pox patients were of a less intimate character than those of the nurses.

One of the latest pieces of evidence of the immunity furnished by revaccination has been brought to my notice by Professor Osler.[1] At the end of October, 1898, the 2nd United States Volunteers were sent to occupy a district in the north of Cuba, which was said to be devastated by small-pox. The men were carefully revaccinated, and it was found on their arrival that the epidemic had been progressing since March and that there were some 4000 cases of small-pox, occasioning 30 deaths a day. By vaccinating 30,000 inhabitants in two months the small-pox mortality was reduced from 29·5 to 9·6 per cent., and the Americans then had the pleasure of burning the isolation hospitals which were no longer needed. Not a single case of small-pox occurred in the Volunteers, though the men were constantly exposed to a most malignant type of the disease, and served for six months in the district. Previously to the arrival of this regiment only 5·6 per cent. of the Cubans had been vaccinated, but it is worth mentioning that none of these died and their cases were all discrete.

Let me very briefly recapitulate the facts which prove the value of vaccination.

1. There has been a marked fall in the mortality from small-pox in all countries dating from the time of introduction of vaccination.

2. The vaccinated suffer much less from small-pox than the unvaccinated. Medical men, for instance, have a well-proved immunity, though in scarlet fever, against which doctors have no special protection, the statistics show that 59 per 1,000,000 die, as against 16 per 1,000,000, of the general population.

3. The age-incidence of small-pox is quite different since the introduction of vaccination. Formerly most children took it, and in Gloucester, where 85 per cent. of the children were unvaccinated, 64 per cent. of the patients in the small-pox epidemic of 1898 were children under ten years of age. To-day, where infantile vaccination is thoroughly carried out, most of the patients are adults; for instance, in Glasgow in 1900 only 5·5 per cent. of 1730 small-pox cases were under the age of ten, and of these children two-thirds had never been vaccinated.

4. The vaccinated, even if not efficiently protected by revaccination, have a much lower death-rate when attacked by small-pox than the unvaccinated. In the London epidemic of 1900–01, 9659 cases were treated in the small-pox hospitals of the Metropolitan Asylums Board, and of these 11·5 per cent. of the vaccinated and 33·1 per cent. of the unvaccinated died.

5. Systematic successful revaccination protects from small-pox. The German Government in 1874 made vaccination obligatory during the first year of life and revaccination at puberty. Since 1875 there have been no epidemics of small-pox in Germany, and the disease there is almost extinct. It is frequently introduced by foreigners, particularly on the Russian and Austrian frontiers, but it can find no resting place. In Prussia, where the population has been steadily increasing from 35 to 38 millions, the small-pox deaths for six years have varied from 10 to 41, being an average of considerably less than 1 per 1,000,000. This figure compares well with the year 1872, when 2700 Prussians per 1,000,000 died from small-pox.

6. In many small-pox hospitals it has been necessary to keep healthy children for weeks in the wards whilst their mothers underwent the disease; the children remained healthy, and were protected by one thing only—prompt vaccination.

There are several points connected with the question of vaccination which I venture to think are not always remembered. Jenner hazarded the guess that vaccinia was small-pox modified by passing through the cow, but for many years after his death no one could explain how the immunity was acquired. Proof has recently been obtained that monkeys can be infected with both vaccinia and variola, and that in them the diseases run much the same course as in man.

In Dr. S. Monckton Copeman's experiments human small-pox material was first tested on calves, but always with negative results. But inoculation of this material on monkeys invariably proved successful, and when, after one or more passages through monkeys, calves were again inoculated, an effect was produced which, after one or more removes in that animal, could not be distinguished from typical vaccinia. From the vesicles of these calves children were vaccinated, and every one of these vaccinations passed through its course normally. The importance of these experiments consists in the fact that they gave us scientific confirmation, to an extent previously unattained, of the definite relationship of cow-pox to small-pox. The mystery has yielded to investigation, and we may now agree that vaccinia is small-pox which has lost its virulence and its infectious character. Jenner's labours have helped to make the present generation understand the idea of immunity from specific diseases and the methods of procuring temporary immunity by introducing into the body a weakened or altered form of the virus producing the disease. Small-pox no longer stands alone as the one disease which we can prevent by vaccination, for, to mention human diseases only, we have acquired means of preventing, under certain circumstances, hydrophobia, plague, cholera, and typhoid fever.

Jenner before his death was forced to the conclusion that vaccination did not protect an individual from small-pox for the whole of his life, and we now know that the operation must be repeated at intervals in order to ensure the highest degree of protection which vaccination can give. Is the value of revaccination, say at puberty, sufficiently brought before the public by the profession? At how many schools in this country is it systematically carried out? Have we, the legitimate advisers of the public, not become somewhat supine and allowed our opponents to capture too many strongholds?

The Government Lymph Establishment at Colindale-avenue, N.W., supplies the army and all public vaccinators with excellent calf lymph, glycerinated, bacteriologically examined, and so prepared as to make it impossible to convey any other disease; but this lymph is, unfortunately, not available for the private practitioner. During the year ending March, 1909, the number of tubes of lymph despatched was 499,820, each tube containing sufficient lymph for one vaccination. Reports from 446,492 cases show 99·3 per cent. case success and 95·9 per cent. insertion success. The year's lymph was derived from 320 calves, all of which were examined after death and certified to be healthy. Four other calves, which seemed healthy during the course of their vaccination, proved at the necropsy to exhibit evidence of tubercle; none of the lymph from these four calves was issued.

In Germany there are said to be 22 State laboratories for the preparation of glycerinated calf lymph. It is regrettable that in Great Britain there is but one. The private practitioner can procure reliable lymph from at least two well-known institutes in London as well as from other vendors, none of whom, however, are under Government control, so that he has, for the most part, no guarantee as to the age and quality of the lymph, or as to its source of origin.

Is the operation of vaccination always performed under strict aseptic precautions? What instructions are given to the mother about the after-care of the vaccinated arm? Public vaccinators, whose work is inspected by the Government, and who receive a money grant in proportion to their success, strap a pad of wool, with or without a sprinkling of boracic powder, to the child's arm and forbid any interference with the arm for a week. Others, who are content to use no precautions, or to tie a dressing to the arm which the mother can remove at will, would be horrified to see the septic tricks which are sometimes played at home with the sore arm, and in such cases it is wonderful that abscess and erysipelas do not more often occur. Again, the public vaccinator inserts lymph into at least four places, and naturally complains that some of his colleagues, to please the friends, make only one or two insertions. Judging by

[1] Small-pox as Found and Treated in Cuba during the Spanish-American War, Pennsylvania Department of Health, August 9th, 1909.

analogy, we should expect that one insertion might be sufficient, but we know from the statistics of many small-pox hospitals that the highest protection is afforded by a total area of marks of not less than one-half of a square inch. The public vaccinator further complains that his unofficial colleagues sometimes give a certificate as successful vaccination when there is only one spot of doubtful value. If such a patient eventually contracts small-pox this obviously throws discredit on the value of vaccination.

I feel constrained to mention these criticisms because, with the present facilities for obtaining pure calf lymph, I do not see why the Registrar-General should have to report every year a few deaths from "cow-pox and other effects of vaccination." Lastly, we may agree with antivaccinationists that general hygiene, including prevention of overcrowding, prompt diagnosis and isolation, disinfection, and watchful care of contacts, are all valuable auxiliaries in the fight; but, in the words of Milton—

> "What boots it at one gate to make defence,
> And at another to let in the foe?"

Cavendish-square, W.

A FATAL CASE OF ANÆMIA IN WHICH THE WIDAL REACTION WAS OBTAINED.

BY PERCY GULLY, M.R.C.S. ENG., L.R.C.P. LOND.

A CASE of pernicious anæmia complicated by enteric has probably never been recorded. This may have been such a case, and it is as well that it should not go unnoticed.

The patient, an unmarried girl, aged 22 years, had been healthy and of good colour until the present illness. She had always been subject to slight menorrhagia, which, however, had never affected her health and had been no worse latterly. She had never had typhoid fever or any symptoms pointing to it. Measles had been her only illness. The patient thought that her illness dated from about August 20th, 1909, when she began to notice dyspnœa on exertion. She consulted her medical attendant on August 28th. He found her a little paler than usual and there was a hæmic bruit. She was put on iron and arsenic, given suitable directions, and seen again on Sept. 10th. She was no better, but a careful examination revealed nothing further. Her temperature was normal. There was nothing at this time to suggest to the medical man in attendance, a very able and experienced physician, that this was the commencement of a serious and fatal illness. On the 20th she left home for a change of air and came under my care for the first time on the 28th. From the time she left home she became rapidly worse, weaker, paler, and more breathless, and was compelled to take to her bed on the 29th. She did not improve, and four days later I was asked to see her. For about a month before this she had been slightly constipated. There had been no wasting. She thought she had had slight occipital headache about a week ago (? Sept. 21st). The headache had lasted only one day. The patient menstruated at the usual time early in September. She had had no abdominal pain, vomiting, diarrhœa, melæna, cough, rigors, or sweating—in fact, no symptom beyond what has been recorded. The following notes of the patient's condition were made on Sept. 28th:—"Deadly waxen pallor, suggesting pernicious anæmia. Rather inclined to be stout. Face full, not in the least drawn or cachectic. Pleasant expression. Talks cheerfully, but is breathless. She lies on her back. Pupils equal and moderately contracted. Skin dry. She has no pain. Pulse 120, low tension; temperature 100·5° F.; respirations 26 when quiet, but alarming dyspnœa on least exertion. No restlessness. Very healthy condition of teeth and gums. Tongue pallid but not furred. No enlarged lymphatic glands. *Heart:* Diffuse impulse in nipple line fifth space. Systolic bruit all over cardiac area. Most marked at second left space. Is carried from apex into axilla. Heard below scapula. Carotids throbbing. No obvious increase in cardiac dulness. *Lungs:* Nothing to be noted about lungs and pleura except feebleness of respiratory murmur all over chest. *Abdomen:* No distension or rose spots. Abdomen moves well. No sign of free fluid in peritoneum. No pain or tenderness on deep pressure. No enlargement of liver or spleen is evident. No mass or resistance in pelvis or elsewhere. In fact, abdominal examination quite negative. Rectal examination not made at this time, but subsequently a thorough examination gave negative result. Urine: S.G. 1020, alkaline, amber-coloured, no sugar or albumin. No diminution in quantity has been noticed." The condition of the patient remained about the same during the 29th and 30th. The period commenced on Oct. 1st (a few days before expected). There was slight epistaxis on this day. The period lasted four days and there was slight menorrhagia during second and third days. Menstruation almost ceased on the fourth day. On Oct. 3rd the patient complained of slight blurring of vision of the left eye. On the 4th she had blurring of vision in the right eye, but the left eye was almost well. The pupils were equal and not dilated. The right pupil was dilated and the fundus was examined. Recent retinal hæmorrhages were seen. The fundus was very pale. Widal's test was negative. A blood count gave red cells 1,500,000, hæmoglobin 25 per cent., and colour index 0·83. Films showed slight poikilocytosis; no nucleated red cells and no obvious leucocytosis. On the 5th, 6th, 7th, and 8th there were troublesome vomiting and nausea. The temperature was of remittent type. The patient obviously was in a desperate condition. Syncope and dyspnœa intervened on the least exertion. The constipation was easily relieved by enemata. The patient's expression was becoming anxious and she refused a great deal of the fluid food offered her. On the 7th she looked like a corpse. There was a peculiar odour about the bed—a cadaveric odour. During the last three days of her illness the pulse-rate was between 130 and 140, and the respirations ranged from 30 to 40. On the 8th the medical attendant already referred to and myself examined the blood and the result was somewhat remarkable, giving red cells 572,000 per cubic millimetre, hæmoglobin 14 per cent., and a colour index normal or slightly above it. Films showed few poikilocytes and no obvious leucocytosis. Nucleated red cells were not seen in the two films examined. This examination was done 18 hours before death, and while doing it I took another specimen for a Widal test—quite as an after-thought. The result (not known until after the patient's death) *gave a positive reaction in dilutions of 1 in 30 and 1 in 50 within one hour.* This dilution and this time would make the reaction a very certain one. On the morning of the 9th the patient died after a night of delirium, alternating with intervals of complete consciousness. No post-mortem examination was made, but a thorough bimanual examination of the abdomen and pelvis revealed nothing to suggest internal hæmorrhage.

I may say that her own medical attendant was astonished at the pallor of his patient on Oct. 8th, just a month from the time he last saw her. He believed her case to be one of the severer anæmias, and he did not alter his diagnosis when I told him of the positive Widal reaction—a reaction in such a dilution and in such a time as to make it almost a certainty that the patient giving it was suffering or had suffered from enteric fever. I must say that I agree with him, but typhoid fever may have come in as a complication. Oral sepsis was absent, and this plus the fact that no nucleated red cells were seen in the two or three films examined are the only points against acute pernicious anæmia, complicated, it may be, with enteric fever in an early stage. The colour index had risen between the counts of Oct. 4th and 8th. It is reasonable to suppose that a further rise might have occurred. A blood count so extraordinarily low as 572,000 recalls the fact that Osler's series of 18 cases, in which the blood was examined on the day of death, all exhibited less than 700,000 red cells per cubic millimetre. My count was made 18 hours before death, and, so far as I know, in no condition other than pernicious anæmia is such a diminution of red cells observed.

Is it possible that some cases of the severer anæmias possess a blood serum abnormally charged with the substances which cause Eberth's bacilli to agglutinate? Although I put this forward as a mere possibility, it does seem worth while to test the agglutinating power in similar cases. An exceptionally high agglutinating power would be *additionally* suggestive of an intestinal origin to these fatal cases, and might give some hint as to the nature of the organism causing pernicious anæmia. It will be observed that the whole of the illness only occupied seven weeks. Osler relates a case which was fatal on the tenth day.

I am aware of the deficiencies in these notes from the pathologist's point of view. Notwithstanding this, I feel that such a remarkable case ought not to go unrecorded.

The case was treated as one of pernicious anæmia with a restricted diet in view of the possibility of enteric being a complication.

Shanklin.

ON THE USE OF PITUITARY EXTRACT IN OBSTETRICS AND GYNÆCOLOGY.[1]

BY S. JERVOIS AARONS, M.D., C.M. EDIN., M.R.C.P. LOND.,

GYNÆCOLOGIST TO ST. ANTHONY'S HOSPITAL, NORTH CHEAM.

THE briefest possible mention of the anatomy, physiological properties, pharmacology and therapeutic action of the pituitary gland and its extract will be useful to introduce my subject.

Anatomy.—The pituitary gland consists of three parts—the anterior lobe, the pars intermedia, and the posterior lobe. The anterior lobe (hypophysis) is the larger and is made up of cubical or polygonal epithelial cells; in structure it is rather like the fœtal thyroid (Blair Bell[2]). Disease of this part of the pituitary gland is associated with the condition known as acromegaly. The pars intermedia lies between the anterior and posterior lobes and is developed in connexion with the anterior lobe. The posterior lobe is connected with the floor of the third ventricle, from which it is developed by the neck or infundibulum. In man both neck and body are solid, with traces of a cavity in the neck.

Physiology.—In the earlier days of medicine physicians held the idea that the function of the pituitary gland was to secrete nasal mucus, and from this belief the gland derived its name (pituita = mucus or phlegm). It was shown that removal of the gland in its entirety in animals produced great depression, increasing muscular weakness, dyspnœa, progressive emaciation, and finally death. Removal of the anterior lobe leads to genital infantilism. The pituitary gland generally hypertrophies after removal of the thyroid and suprarenal glands, and after castration. Insufficiency of the pituitary gland is associated with muscular weakness, wasting, and modification of the skeletal structure. Excessive secretion of the pituitary gland is followed by high arterial tension, polyuria, glycosuria, and acromegaly.

Pharmacology.—In 1894, Schäfer and Oliver[3] discovered that the extract made from the whole pituitary gland, when injected intravenously, caused a marked rise in blood pressure akin to, but not so powerful as, that caused by the extract of suprarenal gland, which they first discovered. Later, Howell[4] showed that this rise of blood pressure was produced only by an extract of the posterior and infundibular portion of the gland, and this observation was subsequently confirmed by Schäfer and Vincent.[5] The rise of blood pressure is due to a general vaso-constriction, the beat of the heart being, as a rule, slower. Schäfer and Magnus[6] observed that the extract of the posterior and infundibular portions of the gland caused marked diuresis. It was found by H. H. Dale[7] that uterine contractions were produced by intravenous injections of an extract of the gland; later, Blair Bell and Hick[8] described more fully the action of pituitary extract on the uterus and were the first to point out its effect upon intestinal muscle. It may be said that the extract of the posterior lobe and infundibular portions of the pituitary gland is a general stimulant of plain muscle, the organs which appear specially affected being the arteries, spleen, and uterus. The active principle diffuses slowly through animal membrane. It is less active than the suprarenal extract in producing local anæmia. It is absorbed slowly from the stomach and is destroyed by pancreatic digestion. It should therefore be administered by intramuscular or intravenous injection.

Therapeutics.—The first to use pituitary extract clinically was F. Golla.[9] A patient suffering from advanced Addison's disease was given a subcutaneous injection from which a marked rise of blood pressure and diuresis resulted, the latter continuing for 24 hours. Delille[10] tried the extract in such various conditions as typhoid fever, tuberculosis, Graves's disease, and paralysis agitans, as a result of which experience he recommended it in those conditions when it is considered desirable to raise the blood pressure, lessen the rate of the pulse, produce diuresis, and exert a stimulating effect on nutrition. To Blair Bell, however, belongs the chief credit of having systematically used the pituitary extract clinically. He, after numerous experiments on animals in conjunction with Hick, gave it a thorough trial in cases of shock, uterine atony, and intestinal paresis. The value of the extract in shock had been previously pointed out by Lockhart Mummery and Symes,[11] but only experimentally, because they were deterred from using it clinically owing to the powerful action of the extract and uncertainty as to the uniformity of its preparation at the time.[12] In June, 1909, through the courtesy of Messrs. Burroughs, Wellcome, and Co., who supplied me with a quantity of the extract, I was enabled to give the drug a thorough trial. The extract of the infundibular body of the pituitary gland is put up and placed on the market by Messrs. Burroughs, Wellcome, and Co. in hermetically sealed glass flasks which they have issued under the name of "Vaporole," each vaporole containing 1 c.c. of sterile extract equivalent to 0·2 gramme of fresh posterior lobe and infundibular portion of the pituitary gland. As the activity of the preparation is not destroyed by boiling, each flask and its contents are sterilised in this manner. The stability of the pituitary extract has been proved by comparing a sample a year old with a fresh preparation, and the effects produced by the two samples were equal within the limits of experimental error. The contents of each vaporole constitute the ordinary dose for an adult, whilst for children the dose should be proportionately diminished. An extract of the infundibular portion of the pituitary gland is also put up by Parke, Davis, and Co., under the name of "Pituitrin" in ampoules containing 0·5 c.c.

When it is necessary to give a second dose it should be remembered that such will not produce more than a small fraction of its proper effect unless some time has elapsed since the previous dose was given. It is important to note that infundibular extract, like other powerful pressor substances, has been shown experimentally to produce arterial degeneration if administration is long continued. (I shall refer to this again.) The extract is essentially a remedy for emergencies and is only to be used in a routine method with the greatest possible caution. I append here a short note of some of the cases in which I have used the pituitary extract. I have applied it in 70 cases altogether, but, as many of these were of a similar nature, for the sake of brevity they are not all particularised. For the purpose of contrasting this preparation with that of ergot and its allies—namely, ernutin, tyramin, &c.—I have used the pituitary extract in a number of cases of normal labour and have found that the uterus contracts better and more quickly and that the contraction remains for a longer period than when ergot or the other preparations have been employed. I have never used it, nor do I think it should be used, until after the completion of the third stage of labour, with the possible exception of certain cases of placenta prævia. The only drawback at present to its general use is on the score of expense, but it is within the bounds of possibility that the active principle of the infundibular portion may be synthesised by chemists, when the cost will be materially reduced.

CASE 1.—A woman, aged 27 years. Secundipara. Her first parturition was an interesting one. The child weighed 12¾ pounds. There was marked deficiency of liquor amnii. The head was in the right occipito-posterior position and could not be rotated, being delivered in this position with forceps. The placenta and membranes were adherent and had to be removed manually. There was smart post-partum hæmorrhage which was checked by an intra-uterine douche of water at a temperature of 120° F., an intramuscular injection of ergotin, and by kneading the

[12] Since the above paper was written an interesting article by Mr. George Rowell, senior anæsthetist at Guy's Hospital, has appeared in which he gives his experience with pituitary extract in the treatment of shock. Brit. Med. Jour., Sept. 17th, 1910, p. 757.

uterus. Her second labour was induced at the thirty-eighth week owing to the large size of the fœtal head, which was in the right occipito-posterior position, but was easily rotated. Delivery was accomplished normally, but the placenta had to be expressed by Credé's method. There was some post-partum hæmorrhage, but not so severe as in the first labour, which was controlled in the same manner as in the first confinement. The third labour was normal as far as position and delivery of the child was concerned, but again the placenta had to be expressed, immediately after which there was a smart rush of blood. An intramuscular injection of the pituitary extract was given and the bleeding ceased at once, while the uterus was firmly contracted and remained so for over three hours.

CASE 2.—A woman, aged 38 years. Secundipara. This case was one of placenta prævia; the bleeding commenced at the fourth month, but was checked by rest in bed, opiates, and neutral cotarnine phthalate. It recommenced at the fifth month and continued intermittently until five and a half months, when there was a smart hæmorrhage. The membranes were ruptured, version was performed, and a leg brought down, the fœtus being expelled naturally three hours later, the placenta being adherent and having to be removed manually, which procedure was accompanied by profuse hæmorrhage. An intra-uterine douche of weak perchloride of mercury was given at a temperature of 120° F., and pituitary extract was injected deeply into the buttock, after which there was no further loss and the uterus remained well contracted.

CASE 3.—A woman, aged 36 years. Secundipara. Labour was precipitate, the second stage consisting apparently of only a couple of pains; the child was born before my arrival, the nurse informing me that it was literally shot out, and the placenta followed in half an hour, by which time I was with the patient. There was considerable hæmorrhage; pituitary extract was injected deeply into the buttock and the bleeding ceased at once, the uterus contracting firmly.

CASE 4.—A woman, aged 32 years. A primagravida. Labour was uneventful, but after the expulsion of the placenta the uterus was relaxed and flabby, though no bleeding occurred. An intramuscular injection of pituitary extract was given, when the uterus immediately contracted and remained so.

CASE 5.—A woman, aged 37 years. A large multilocular ovarian cystoma, with a twisted pedicle and numerous adhesions, was removed without rupturing the tumour, but the adhesions were difficult to separate and caused some delay. At the completion of the operation, which lasted nearly an hour, the patient was in a state of shock, the pulse being small and compressible. Rectal injections of normal saline solution and an intramuscular injection of pituitary extract were given, the effect being instantaneous, and the pulse immediately became full and the tension high. On the second day there was a good deal of abdominal distension, and as no flatus had been passed a rectal injection of turpentine was given, the rectal tube being passed later but without result. As her condition now gave rise to some anxiety and the patient was restless and complained a great deal of pain, an intramuscular injection of pituitary extract was given, and in 15 minutes large quantities of flatus were passed. From this time on she made a rapid and satisfactory recovery.

CASE 6.—A woman, aged 28 years. This was a case of subinvolution of the uterus, the patient suffering from menorrhagia, for which she had recently been curetted but with no satisfactory result. Her uterus was enlarged (the cavity measuring 5 inches) and flabby, her tissues generally were soft and flabby (she might be termed "of the heavy lethargic blonde type"), and her blood pressure was low. I decided to try what effect repeated doses of pituitary extract might have, and accordingly gave her an intramuscular injection of this drug, taking her blood pressure at intervals, giving in all six injections spread over as many weeks. I was justified in my expectations, for her uterus contracted down, the cavity of that organ when measured by the sound being found to be 3 inches, while her general condition was much improved, for, in her own words, she "had not felt so well for many years," and after the lapse of six months her condition is still quite satisfactory. Incidentally, I might add that during the administration of the pituitary extract she had marked polyuria.

In recording this case I must refer to my remarks concerning the routine use of pituitary extract. I still think that this drug is one for emergency cases, but the low blood pressure and general flabby condition of this patient warranted, in my opinion, a trial of pituitary extract. In this particular case there have been no deleterious effects whatever, such as arterial degeneration. These cases, however, are few and far between, but should one of a similar nature present itself to me I should be inclined to repeat the experiment. I can find no recorded instance of the employment of this drug in subinvolution of the uterus, and only suggest its use in this condition provided that the subinvolution is associated with a low blood pressure.

CASE 7.—A woman, aged 24 years. This was a case of secondary hæmorrhage following an operation for perineorrhaphy. I was called in consultation by the medical man who had performed the operation the previous afternoon. The nurse was apparently an incapable woman who had not noticed that the patient was bleeding, and it was not until the following morning when the doctor paid his visit that the condition was recognised. He immediately sent for me, and when I arrived the patient was blanched and pulseless, she was sighing and throwing her arms about, but when I examined her I could see no signs of bleeding. The wound had broken down slightly but the bleeding had ceased, and as her condition was grave in the extreme I gave her an injection of pituitary extract and a large submammary injection of normal saline solution. The wound was plugged tightly with gauze steeped in adrenalin solution, a firm bandage applied, and continuous injections of normal saline solution were ordered to be given by the bowel. In less than 20 minutes after the injection of the pituitary extract the pulse was perceptible at the wrist, and in an hour it was quite distinctly beating at the rate of 120 per minute. I ordered another dose of pituitary extract to be given in an hour's time, and next morning her pulse was still 120 beats to the minute but full and of good tension. The pituitary extract was repeated twice that day and saline injections were continued. The patient made ultimately a good recovery, and I am convinced that she owed her life to the use of the pituitary extract.

CASE 8.—A woman, aged 23 years. Primipara. Her first labour was terminated by forceps owing to a tedious second stage. The child in the present labour also had to be delivered with forceps owing to inefficient pains; there was smart post-partum hæmorrhage caused by an atonic uterus, but this was quickly checked by an injection of pituitary extract deep into the buttock.

CASE 9.—A woman, aged 37 years. This was a case of a large multilocular ovarian cystoma weighing 10 pounds. There was no difficulty in the operation, the cyst being removed intact, but the patient developed intestinal paresis and retention of urine; the latter was relieved by catheterisation, but the former, which was causing acute discomfort, was not relieved until after the injection of pituitary extract; 20 minutes later a large quantity of flatus was passed, which gave the patient much relief. She was up on the tenth day, and left the nursing home at the end of the second week.

CASE 10.—A woman, aged 22 years. This patient had an ectopic gestation at about the third month, the operation presenting no difficulty beyond some adhesions of the sac to the bowel which took a little time to separate. There was a considerable amount of intestinal paresis on the third day, which yielded promptly to an injection of pituitary extract.

CASE 11.—A woman, aged 32 years. This was a case of abortion, the removal of the ovum being accompanied by the most alarming hæmorrhage which it has been my lot to see. The ovum was removed in its entirety, but the hæmorrhage still continued and douches of water at a temperature of 120° F. failed to check it; the uterus was firmly packed with gauze and an injection of pituitary extract was given, after which the patient was put back to bed very collapsed and in a state of profound shock. Next morning, on removing the gauze plug, the hæmorrhage recommenced, but was checked by another injection of the same drug. Later there was considerable abdominal distension accompanied by great pain, and a third injection of pituitary extract was given which resulted in the passage of large quantities of flatus with considerable relief to the patient. I have never seen a case of abortion accompanied by such a tremendous loss of blood as this patient suffered, or one which gave rise to so much anxiety. Her convalescence, although prolonged, was ultimately complete.

Of the other cases in which I have used this preparation I do not propose to speak, as some were normal confinements and the others were cases similar to those I have already mentioned. In order to economise time I have condensed the notes of the cases reported above to the narrowest limits, but I think that I have mentioned a sufficient number to warrant my laying before the notice of this important assembly so valuable a drug as pituitary extract as an addition to our armamentarium in the treatment of hæmorrhage, intestinal paresis, and shock.

Harley-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PROTRUSION OF THE URINARY BLADDER INTO THE INGUINAL CANAL.

BY A. H. GIFFORD, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON, ROYAL SURREY COUNTY HOSPITAL, GUILDFORD.

AN interesting condition, and one of some import, is that of protrusion of the urinary bladder through the anterior abdominal wall in the inguinal region. I have recently met with two such cases. In both instances the patients were sent into hospital for radical cure of inguinal hernia.

The first case was that of a child 5 years of age. The "rupture" was on the left side in the inguinal region, and had only been noticed for five months or thereabouts. No swelling was present when the patient stood upright, even after he had been on his feet for some time. Both testicles were in the scrotum. There was a scar on the right side resulting from an operation for a cure of a "rupture" when a baby. On coughing there was a protrusion on the left side of a swelling of the size of a date in the lower half of the inguinal canal, but which immediately disappeared; repeated coughing did not increase the size of the swelling. On inverting the scrotum by the finger and introducing it into the inguinal canal no evident rupture was felt, and the external abdominal ring was not large.

On Nov. 1st, 1909, an operation was performed with a view of curing an inguinal hernia; it was found, however, that no hernial sac was present, but there was a weakening of the abdominal wall external to the conjoined tendon, and a protrusion of a thick-walled sac, which on investigation proved to be the urinary bladder. The very thin fibres covering the protruding mass were divided in the direction of

the fibres—viz., parallel to Poupart's ligament, and the weakness remedied by stitching together the inner and stronger fibres of the external and internal oblique muscles to Poupart's ligament above the cord.

The second case was that of a man aged 33 years. The rupture was said to have been produced three weeks previously by straining. As in the previous case there was a swelling at the lower part of the inguinal canal only on coughing, but which immediately disappeared, and which was not present except during the act of coughing. The swelling was on the left side and was of about the size of a chestnut.

An operation was performed on Feb. 4th, 1910, but no hernial sac was found; it was noticed, however, that there was some bulging of the posterior wall of the inguinal canal, and on turning the cord outwards there was revealed an area external to the conjoined tendon and above Poupart's ligament, where the muscular support was entirely wanting, and through which protruded a thick-walled viscus, which proved to be the bladder. The repair of the wall was accomplished by stitching the conjoined tendon and internal oblique to Poupart's ligament beneath the cord, and the external oblique to Poupart's ligament above the cord as in the ordinary operation for radical cure of an inguinal hernia.

In both cases the bladder was uncovered by peritoneum.

I am indebted to Dr. W. B. De Jersey and to Mr. A. H. Brodribb for permission to publish these cases, which I hope may be of interest.

Bassett-road, W.

NOTES ON A CASE OF PAROXYSMAL TACHYCARDIA.

BY J. A. DRAKE, M.B. LOND., M.R.C.S. ENG.

THE patient was a healthy looking, well-developed male, aged 29 years. When I was called to see him he was complaining of "palpitation," slight difficulty in breathing, and moderate pain in the chest, behind and to the left of the upper part of the sternum. His appearance was normal except for very slight cyanosis, his respirations were somewhat embarrassed (24 per minute), and he had some difficulty in drawing a long breath. He said that he felt quite well except for slight difficulty in breathing and moderate disinclination for food. The pulse was very rapid (200 and more), regular, but small and perceptible only with difficulty. There were no cerebral symptoms, the extremities were warm, and the capillary circulation there quite normal. An examination of the chest showed the apex beat to be in its usual position internal to the nipple and visible as very rapid pulsation. There was no increase of cardiac dulness. The rate of the heart was about 200 beats per minute; there were no murmurs; the first and second sounds followed each other with no apparent interval, and had a somewhat flapping character. There were no signs in the lungs and the urine was normal. The symptoms persisted for nearly 24 hours and then suddenly stopped.

The first attack occurred when the patient was 14 or 15 years of age, coming on when he was sitting down at school. No reason could be assigned for the onset. Since then he has had on an average two attacks a year, more or less. The tachycardia is sometimes brought on by a sudden shock, such as slipping while walking; sometimes apparently it stops for the same reason. Usually, however, no reason can be given either for its onset or cessation. The patient says that before the attack ceases he becomes conscious of an increasing pain behind the sternum, and that soon afterwards the symptoms disappear, and the heart-rate suddenly returns to normal.

The duration of the present attack was by far the longest of any; he attributes this to the fact that he went to bed and stayed there instead of keeping about as is his usual custom. When seen on the following day he appeared perfectly well except for a furred tongue. The pulse was 80, strong, and regular. His only other illnesses have been malaria when abroad and appendicitis. He is not an excessive drinker or smoker. No other members of the family suffer from the same symptoms, neither is there any history of epilepsy or any neurosis.

Treatment in the present instance consisted of strong doses of sal volatile and spirit of chloroform slowly sipped, given with the idea of exciting a reflex action on the heart *viâ* the gastric nerves, and later painting the region of the vagus in the neck with the liquor iodi fortis. The attack stopped shortly after the latter treatment, so possibly it may have had some effect. A subsequent attack appears to have been cut short by the sipping of hot, strong coffee.

ROYAL SOCIETY OF MEDICINE.

LARYNGOLOGICAL SECTION.

Epidiascope Demonstration, illustrating the Topographical Anatomy of the Rigid Resistances of the Larynx and Adjacent Parts.—Exhibition of Cases and Specimens.

A MEETING of this section was held on Dec. 2nd, Dr. P. WATSON WILLIAMS, the President, being in the chair.

Dr. R. H. SCANES SPICER gave an epidiascope demonstration of lantern slides illustrating the Topographical Anatomy of the Rigid Resistances of the Larynx and Adjacent Parts, bearing on the subject of the sites of initiation and maximum development of cancer of the larynx. A statement on the agenda paper ran as follows: "The object of this demonstration is to present some of the evidence available for the conclusion that the sites (*a*) of initiation, (*b*) of maximum development of laryngeal cancer are determined by the mechanical interaction of the rigid resistances of the laryngeal endo-skeleton on the one hand and certain cell constituents (e.g., epithelial and fibrous) of the soft tissues (e.g., mucous membranes) on the other. The larynx, from the ease with which it can be inspected, is peculiarly advantageous for the clinical study of the origin of internal cancer. It has the disadvantage that laryngeal cancer is comparatively rare. In both these respects a marked contrast appears between the larynx and the stomach. According to the American mortality returns, in every hundred cancer deaths 43 are stomach to 1 larynx, while in the English in every hundred cancer deaths 21 are stomach to 1·8 larynx (Roger Williams). In the seventieth annual report of the Registrar-General for England and Wales the total number of deaths from larynx cancer per year (seven years average) is only 313. Again, Sir Felix Semon's series of 246 cases took him over 30 years to collect at the rate of 8 per annum. As but few cases, then, are likely to be seen by any individual laryngologist at a sufficiently early stage to be watched throughout so as to test inductively the suggested causal relationship, it is the collective observation of many specialists directed to the point at issue that is required. This should soon confirm or disprove the alleged connexion. Deductive reasoning on the observations actually made will be, however, pre-eminently necessary since the real origin is but seldom on the *free* surface of the mucous membrane, as seen in the laryngoscope, but somewhere on its *deep* surface, and perhaps in a hidden laryngeal recess. If in an animal with an endo-skeleton—i.e., a vertebrate—certain muscular actions are, from any cause, habitually exaggerated, the corresponding rigid resistances and soft tissues are reciprocally influenced in such a way as to cause undue stress, strain, or friction of those soft tissues—i.e., to produce a chronic, intrinsic, mechanical irritation of the latter. The result is, under certain conditions of nutrition, warmth, moisture, senescence, obsolescence, &c., to stimulate an excessive and disorderly growth of the epithelial, endothelial, or connective-tissue cells entering into their structure. The association of local irritations of extrinsic and palpable origin, such as the pressure of a clay pipe, rough tooth-plate, smoking, paraffin soot, betel-chewing, Kangri stoves, and injury, with the starting of cancer is widely accepted. The 'sharp tooth' irritation cause of cancer forms a natural transition to the view now put forward that hitherto unsuspected intrinsic irritations are even more frequent and potent causes of the initiation of cancer, and this is not only in the larynx but throughout the body. The sites of preference for the commencement of cancer, whether in the gullet, stomach, intestinal flexures, rectum, breast, skin, uterus, &c., are found to be those sites at which the resultant of excessive mechanical forces chronically impinge or act, and where,

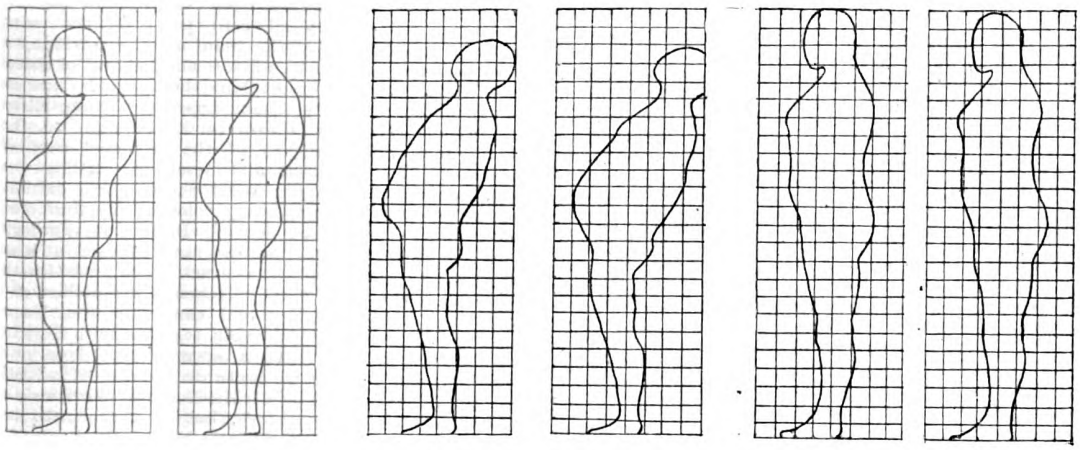
LIV	=	Liver.
SOL	=	Abd. sympathetic.
STM	=	Stomach.
G	=	Gall-bladder.
P	=	Pancreas.
SPL	=	Spleen.
A	=	Adrenals
K	=	Kidneys
PEL	=	Pelvic area.
INT	=	Intestine.
D	=	Diaphragm.

Channels whose patency and efficiency are interfered with by abdominal respiration are indicated by arrows. Longitudinal lines show arterial, and transverse lines show venous, circulation, their decussation indicating the lymphatics. The portal circulation is shown reticulated.

D D. Position at end of thoracic inspiration.
D' D'. Position at end of abdominal inspiration.

FIG. 3.



Shows normal and faulty erect postures.

normally, there is no provision for escaping the consequences of such excess. This is seen if the springy joints, elastic lungs, and contractile muscles, which are little liable to primary cancer, are compared with such areas as the region of cricoid excursion, the œsophageal gastric junction and the rectum opposite the coccyx, where various rigid resistances and soft tissues undergo relative changes of stress and position with reference to each other with often excessive force. The chief muscular mechanisms concerned in producing undue tissue stress, strain, and friction are believed to be (1) the motor mechanism for maintaining equilibrium in posture, (2) that for respiration, and (3) that for digestion; but important factors arise in the relative displacements and mutual pressures of the internal moveable organs constrained in part by mesenteries and ligaments, and also from the artificial compression of the trunk by corsets. Faulty postures and mode of breathing in man, whether from habits, occupation, imitation, intestinal derangements, or other causes, bring about persistent portal congestion, intestinal stasis, and general autotoxæmia. This is especially seen in marked types of belly-breathing, in which *habitual inspiratory descent* of the diaphragm takes place, with *no* expansion of the base of the thorax by the muscular mechanism of respiration. Such abnormal muscular action of the diaphragm tends to produce, simultaneously but independently, two things: (1) abnormal increase of intrinsic mechanical strains and irritation, causing cell overgrowth at sites of impact or restraint—e.g., the inspiratory pulling down of the cricoid; and (2) through relatively lessened thoracic suction chronic portal congestion occurs, leading to intestinal autotoxæmia, general blood cachexia, and hence wasting of the tissues at large. The central nervous system, through the deep afferents and viscero-muscular reflexes, endeavours to coördinate the motor mechanisms so as to minimise undue strain and to adjust the deranged thoracic and abdominal functions, but under the influence of the chronic autotoxæmia, or perhaps from the emotional depression of sorrow, grief, or worry, sooner or later the higher coördinating centres strike work and the mechanical and portal derangements run further riot. In this way the biological syndrome of cancer in the working of the human machine is believed to arise. The power wasted in undue stress, strain, and friction appears to be converted into the energy of those unknown complicated chemical and physical constructive processes concerned in cell growth and multiplication—a marked contrast to those destructive results of similar forces on the material substance of a non-living machine in causing wear and tear." Dr. Scanes Spicer said: "Some may think I am premature in bringing this subject forward yet, but, at all events, I have not been precipitate. As evidence thereof, in debate and in the *British Medical Journal* in 1889,[1] I was upholding the rôle played by the movements of breathing, swallowing, speaking, and generally of injuries from irritation and pressure during functional movement in the production of disease in the larynx; while at intervals ever since I have persistently urged the need for physical training, for erect posture, breathing, thorough expansion of the chest, and special education for the re-acquirement of lost coördinations. My first slide (Fig. 1) is a schema or plan to indicate diagrammatically the centrifugal expansile action of the diaphragm in thoracic inspiration and the centripetal descending action of the same in abdominal inspiration. In Fig. 2 the top part of the schema is shown in larger form. Abdominal breathing produces with every breath: 1. Excessive pulling down of the thorax and the thoracic viscera generally, including the trachea, gullet, cricoid, and sternum, and therefore increased stress, strain, and friction of displaced, stretched, and compressed parts, causing persistent rhythmic mechanical irritation at points of attachment of soft parts, or where these latter are compressed by rigid resistances of the endo-skeleton. 2. (*a*) Displacement, compression, and derangement of the abdominal viscera; (*b*) lessened thoracic suction on the in-breath as compared with thoracic breathing; and (*c*) loss of the normal influence of the expiratory contraction of the abdominal wall in emptying the portal area and promoting the general circulation. Thus are produced simultaneously irritation about the larynx, throat, and gullet (and elsewhere as indicated), and likewise concurrently a blood cachexia. In general terms, I suggest that cancer is the manifestation of a specific biological conjunction, pathological syndrome, or symptom-complex of deranged processes in the working of the body, which processes are: (1) neoplasia from chronic irritation of either extrinsic or intrinsic origin; and (2) a faulty constitutional state or blood cachexia, produced as above. The influence of stress, strain, and friction in the etiology of disease is too well known and accepted to demand illustration here. I am therefore introducing no new factor into etiology or pathology. The novelty of my suggestion is the conception of how the influence of such chronic stress, strain, and friction can arise intrinsically, and can act as such a chronic intrinsic irritation as to cause neoplasia; while in conjunction with this the same deranged bodily working which causes the abnormal stress, strain, and friction brings about simultaneously a chronic constitutional cachexia by deranging the efficiency of the portal system. My interpretation is not in antagonism to any of the ascertained facts of cancer. It is supplementary to them. My next slide (Fig. 3) shows normal and faulty erect postures and how the transmission of the weight of the head and viscera to the ground differs, causing different degrees of stretch and compression about the larynx." Dr. Spicer then showed radiograms of the living subject in which different positions of the head and curves of the cervical spine vary the positions, compressions, and stretching of the larynx. He continued: "The series of coloured lantern slides of photographs of frozen sections which you have seen show clearly and quickly the relations of the rigid resistances—i.e., the bones and cartilages—to the soft tissues about the larynx, and how their conditions would be altered by the different postures and modes of breathing previously shown. If the cartilages are calcified, ankylosed, roughened, or thickened, such conditions must increase unduly the surrounding working stresses, strains, and frictions. These, if chronic and not too great, favour irritative neoplasia in addition to the irritation-factor provided by chronic and habitual exclusive inspiratory diaphragmatic descent. It is curious how cancer in the larynx appears to dog the steps of cartilage. The two best series of operated intrinsic laryngeal cancers are those of Sir Felix Semon and Mr. Butlin. These demonstrate the close association between cancer and cartilage in the fact that the cartilage was usually involved in the diseased mass, and such cartilage had to be removed (if removeable) or scraped at the radical operation. Thus, in Butlin's 13 cases 10 were stated to have cartilage involved; removal of cartilage was indicated in 7 and scraping in 2; in 1 case cartilage was bare: no note as to scraping: growth recurred *in situ*. In Semon's 10 cases cartilages had to be removed in 6. It is generally assumed that cancer spreads, attacks, and causes disease of the cartilage secondarily. I suggest that it is excessive stress, strain, or friction in connexion with the movement, resistance, and sometimes ossification of the cartilage that initiates the neoplasia. This latter subsequently takes its revenge by cutting off the blood-supply of its irritating tormentor. My theory affords a rational interpretation of the natural history of cancer of the larynx. It is in agreement with the age, sex, and site incidences, the left side predominance, the obscure commencement, the diffuse deep origin, the persistent hoarseness, the early vocal cord paralysis, the relative greater extent in the depths than on the surface, and finally the success of laryngo-fissure and removal of diseased parts. What other theory explains these facts? Numerous anatomical diagrams after Quain, Luschka, Killian, Elsberg, and others, especially drawn and coloured to bring out the form and relations of the laryngeal cartilages, particularly the cuneiform and sesamoid cartilages and the anterior and posterior vocal nodules, are exhibited, and a collection of published coloured illustrations of cancer of the larynx by leading British laryngologists. Though it is rare to publish diagrams of such at a sufficiently early stage to define the exact site of initiation there are a few such. Sir Morell Mackenzie's sketches of the earlier stages of the laryngeal cancer of the Emperor Frederick are on view, and, taken together with Gerhardt's description, point to either a sesamoid cartilage or the posterior vocal nodules as probably the site of initiation. Sir Felix Semon's diagram of Mr. Montagu Williams's case apparently opposes my theory, but on the growth being removed it was found to be attached at the back of the laryngeal ventricle about which the arytenoid plays in

[1] Brit. Med. Jour., Sept. 14th, 1889, p. 592.

functioning. At a later stage the relation of the bulk of a laryngeal cancer clustered over a subjacent cartilage is usually apparent and I show many instances."

Mr. HERBERT TILLEY showed an instrument which he had found useful in the Removal of the Nasal Spines in the operation of submucous resection of the septum.

Dr. H. J. DAVIS exhibited: 1. A case of Leprosy being treated with subcutaneous injections of Nastin B. 2. A Thyro-lingual Cyst and a patient who had recovered from Acute Sphenoidal Sinusitis after operation. 3. A boy, aged 7 years, who had suffered from Empyema of the Maxillary Antrum, thought by some members to be due to osteomyelitis of the upper jaw.

Mr. CHARLES A. PARKER showed an interesting Tonsillolith of very large size, successfully removed by traction with forceps.

Dr. ADOLPH BRONNER exhibited a Pedunculated Fibroma of Posterior Pillar of the Fauces.

Dr. W. H. KELSON showed a case of Lupus of the Larynx in a woman aged 36 years; treatment by cautery had been only partially successful, and Dr. Kelson proposed to try tuberculin and show the case again later.

Mr. J. GAY FRENCH showed a case of Stricture of the Lower End of the Œsophagus which he considered spasmodic. Some other members, however, were inclined to deny the existence of spasmodic stricture at all.

Mr. SOMERVILLE HASTINGS showed a case of early Myasthenia Gravis with laryngeal symptoms. The patient was unable to whistle or to close his eyes, but was improving.

Dr. E. A. PETERS exhibited cases showing very good results in which Singer's Nodules had been removed from the cords by means of the galvano-cautery.

Mr. CYRIL A. B. HORSFORD showed a case of Laryngeal Tuberculosis, apparently cured by amputation of the epiglottis and application of pure carbolic acid.

Dr. G. WILLIAM HILL exhibited a case of Carcinoma of the Œsophagus, in which very great improvement—? temporary cure—has been obtained by radium treatment. Also other cases of malignant disease.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held in the Royal Infirmary, Edinburgh, on Dec. 14th, Dr. BYROM BRAMWELL, the President, being in the chair.

Dr. DAWSON TURNER exhibited: 1. A boy, aged 5 years, suffering from a Pigmented Nævus with Hairs of the Left Ocular Region. It had been visible at birth but had been growing. It measured 5 centimetres each way and was brownish-black in colour. It had been treated by the application of 13 milligrammes of radium for 10 hours (130 mg. hours) with great improvement. In places the colour had been washed completely away. As this method destroyed the hair follicles it was not a suitable means of treating angiomata of the scalp. 2. A woman, aged 25 years, who had a port-wine stain of congenital origin on the right cheek, temple, and neck. It measured 2 by 1¼ inches and had been treated with weak preparations of radium since January. Dr. Turner thought that strong preparations of radium were likely to produce permanent atrophy. It was a painless form of treatment.

Dr. F. GARDINER showed a case of Pityriasis Rubra Pilaris in a young boy. The eruption affected the face, arms, and legs on their exterior aspects and closely resembled psoriasis. The eruption had come on only three weeks ago after he had been playing football. This disease was thought to be a tuberculide, and in this case von Pirquet's reaction was slightly positive. Arsenic was usually contra-indicated in such cases, but in the present one great improvement had followed its use, while 2½ per cent. salicylic acid vaseline had been applied externally.

Dr. J. V. PATERSON showed: 1. A man, aged 48 years, suffering from Dystrophia Epithelialis Corneæ (Fuchs). He first had noticed a visual defect eight years ago. On the left cornea, rather below its centre, a patch of epithelium, roughened and œdematous or actually raised into small vesicles, was seen, and in the right cornea a similar but less marked appearance was noted. The sensibility of the corneæ was much impaired; the tension of the eyes was normal. The etiology was unknown. 2. A case of very advanced Arterio-sclerotic Changes in the Retinal Vessels of the Left Eye. The disease was extraordinarily pronounced, and the lower retinal arteries showed as silvery branching lines (silver wire vessels) empty of blood; a large area of the retina was thus rendered bloodless. Many small hæmorhages were scattered over the fundus.

Dr. EDWIN BRAMWELL showed a young man with Brown-Séquard's Paralysis due to a bullet wound. In the middle of August he was behind a hayrick at which his brother was firing with a Lee-Enfield rifle 90 yards distant. He felt a peculiar sensation in the back of his neck, with tingling down the back, but no pain; he then fell down, and was completely paralysed in all four extremities. In this condition he remained for some days, but then the left arm and leg began to improve. At present there was atrophic motor paralysis of the right triceps, hand muscles and extensors, and flexors of the fingers. The oculo-maxillary syndrome was present on the right side; there was paresis of the right leg, with ankle and knee clonus and Babinski's sign. There was loss of temperature and pain sensation on the left side below the fourth rib, with defect of sense of position and bone conduction of the right side. There had been a unilateral lesion of the spinal cord. The entrance wound was situated one inch to the right of the middle line at the level of the seventh cervical spine, and the exit wound at the level of the cricoid cartilage. The lesion affected the seventh and eighth cervical segments and the first dorsal on the right side, both motor and sensory nerves being affected.

Dr. NORMAN WALKER exhibited: 1. A case of Actinomycosis of the Neck and Lower Jaw in a man, aged 31 years, who worked among cattle and often chewed straw. The ray fungus was found at the first examination on Sept. 26th, but it had never been found since. The patient had been treated with potassium iodide, and this drug seemed to have destroyed the fungus. Great improvement had been noted since the man had received two doses of actinomycosis vaccine. 2. A vanman, aged 30 years, suffering from Multiple Sarcoma of the Skin. The disease was first noted eight weeks ago with a vague form of illness; then an attack of rheumatism was followed by one of pleurisy. The earliest lesion appeared on the face, and when the patient was first seen on Nov. 10th there were extensive lesions on the scalp, face, trunk, and limbs. The glands behind the sterno-mastoid and the epitrochlear glands were enlarged and hard. Nodules were present all over the forearms, and hæmorrhages were observed in parts of these; the blood appeared normal. These nodules were observed to have increased in size and number within one week. Under the action of potassium iodide the lesions had improved greatly on the arms, but the tumours on the back were increasing in size.

Dr. G. A. GIBSON showed: 1. Partial Acromegaly in a man aged 32 years. There was evidence of excessive growth of the cranial bones with enlargement of the sinuses, as well as of the facial bones; there was, however, no appearance of hypertrophy elsewhere. 2. A girl, aged 4 years, with a Patent Arterial Duct. She had been observed to become breathless on playing, but was otherwise in perfect health with no cyanosis. There was the pathognomonic thrill and murmur, which began in the middle of the ventricular systole and continued beyond the second sound, which latter was sometimes doubled. Such cases were by no means rare, and in Dr. Gibson's ward at the present time there was a young woman, aged 29 years, with a similar affection.

Professor Sir THOMAS R. FRASER showed cases of Beriberi illustrating the œdematous and the atrophic varieties. The œdematous variety showed the beneficial results of treatment and the atrophic variety the signs and symptoms of peripheral neuritis. The cases occurred in coolies from a ship which traded from Hong-Kong, &c., and this country. Eight Chinamen on board became affected, but none of the white people. On admission cases of the first variety were entirely bloated, the face, hands, feet, and abdomen being greatly distended with fluid. They soon began to improve, and at first passed 180–120 ounces of urine per diem until the fluid was entirely drained away from them. A remarkable fact was the very great distension of the heart, which underwent rapid contraction on the patients being put to bed. In the case of the atrophic variety, certain areas on the lower extremities were painful on pressure, and in these the deep

reflexes had gone; one case showed foot-drop with motor paralysis.

The PRESIDENT showed: 1. A case of Obscure Nervous Disease. It occurred in a dock labourer aged 29 years. Since the age of seven he had had a fœtid discharge from the ear, but he remained well in health until the age of 21, when he gradually developed difficulty in moving the right arm, right leg, left arm, left leg, facial muscles, and tongue, and had had three attacks of difficulty in swallowing. His family history was good. The present condition was that he was a big, robust-looking, tall man, unable to stand or walk, with a vacant expression; mentally he was bright, but unable to speak on account of spasm of the muscles of articulation; his palate was high; the tongue was very large and the point was always turned upwards. Scoliosis was present, and any voluntary movements were attended with spasmodic muscular contractions which passed off on attempting further movements. The muscles reacted briskly to faradism and galvanism, the contractions were not persistent and there was no polar change; the deep reflexes were absent; plantar flexion was present and the organic reflexes were unimpaired. The cerebro-spinal fluid was normal and the sensory functions were normal also. On shutting the eyes there was spasmodic contraction of the muscles which prevented him from opening them for some time. 2. A case of Myxœdema with Ascites. A cure followed tapping and the administration of thyroid extract. The disease occurred in a woman, aged 50 years, who had had typical myxœdema of six years' duration and which followed severe "floodings." Thyroid treatment caused great improvement, and she remained well for three years. With an attack of influenza this treatment was suspended, when the myxœdema redeveloped. On admission she weighed 15 stones 4 pounds, and the abdominal measurement was 48½ inches. Thyroid treatment was commenced and the abdomen was tapped, 400 ounces of yellowish-green fluid being withdrawn. The fluid has not reaccumulated, and the weight has been reduced to 10 stones 11½ pounds, with complete disappearance of the myxœdematous condition.

Professor F. M. CAIRD showed: 1. A Partial Gastrectomy for Carcinoma of the Stomach in a man aged 28 years. A year previously he had suffered from pain in the stomach with vomiting after eating, but medicines relieved him for some months. On recurrence he was admitted to the medical ward and treated for gastric affection. The free HCl was abundant. On operation a malignant degeneration of a peptic ulcer was found adherent to the pancreas. The diseased area was removed and found to be a columnar-celled carcinoma. The patient was now well. 2. A male, aged 55 years, after removal of half of the stomach, a portion of the liver, and 7 inches of the transverse colon for a Large Carcinoma of the Body of the Stomach. On admission a swelling of the size of a cocoanut was seen in the epigastrium. The operation lasted two and a half hours and the patient was transfused while on the table. He had made a good recovery.

Professor H. ALEXIS THOMSON showed: 1. A patient after removal of Impacted Stone from the lower end of each ureter. The patient, a man, aged 29 years, a miner, had had symptoms pointing to renal and ureteral stone for four years. The X rays showed two small shadows placed symmetrically at the level of the floor of the bladder. The stones were removed by the vesical route. 2. A boy, aged 12 years, previously shown to the society, who had had a Periosteal Sarcoma of the Right Humerus removed. Musculo-spiral paralysis supervened, but had been recovered from. The lower half of the humerus became the seat of further new growth, and was resected on Sept. 6th, a portion of the right fibula being inserted in its place. The first operation had been performed more than a year ago, and the case was encouraging, as all the other cases of a like nature which Professor Thomson had operated on had died within a year. He thought this method of resection was quite as satisfactory as amputation.

Mr. DAVID WALLACE showed: 1. A patient after Nephrectomy. The woman, aged 30 years, had been operated on on June 28th for acute suppurating appendicitis. In August she suffered from pain in the right lumbar region. No urinary symptoms developed until September, when she had rigors, and the urine became alkaline with much pus. On Oct. 19th cystoscopy showed a healthy bladder. A perinephric abscess was detected on Nov. 4th, and pointed in the ninth intercostal space; this was opened and showed Gram negative bacilli. On Nov. 29th nephrectomy was performed. 2. A woman, aged 36 years, who had complained of Difficulty in Swallowing for three months subsequent to some trouble with a fish-bone in her throat. Œsophagoscopy showed an annular stricture at the upper end of the œsophagus, and a portion removed and examined microscopically revealed squamous epithelioma. The operation consisted in making an incision along the anterior border of the left sterno-mastoid and excising the tumour. The upper end of the œsophagus was fixed to muscles and skin, and an œsophageal tube was introduced. There were no enlarged glands.

Mr. H. J. STILES showed: 1. A boy, aged 10 years, six months after operation for Congenital Hydronephrosis. He had had a fall four weeks before admission, and this was thought to have caused his symptoms. The abdomen had, however, been unduly large since birth. On admission the left iliac fossa was alone tympanitic; the urine contained a little albumin and red blood corpuscles. The cyst occupied the greater part of the abdomen, the apex beat being pushed up to the third left interspace. The cyst was excised extraperitoneally after having been tapped and 7½ pints of dark brown liquid with a urinous odour having been drawn off. The pedicle was very broad, and numerous large veins were present. The operation was done from the lumbar region, but Mr. Stiles found that the transperitoneal route was the most easy. 2. A patient, six weeks after Nephrectomy for Acute Infection of a Hydronephrotic Kidney. Three days before admission the man was suddenly seized with abdominal pain at the site of a former operation for appendectomy done 18 months previously. The abdomen was somewhat distended and tense, and the patient was admitted as a case of acute obstruction. The operation revealed no obstruction or adhesions, but an acutely inflamed hydronephrotic kidney which contained 10 to 12 ounces of sero-purulent fluid.

Mr. GEORGE L. CHIENE showed a patient after operation for Ruptured Ectopic Ovarian Gestation. She had complained of pain on the right side for three days previous to operation, but was suddenly seized with pain and collapse. She was sent to hospital as a probable case of acute appendicitis, but on examination the real cause was diagnosed. The menstrual history was misleading, as she had been absolutely regular, and expected her menstrual period within three days. The abdomen was full of fluid blood and clots, and the right ovary was ruptured, showing it to have been a true case of ovarian gestation.

Mr. J. W. STRUTHERS showed: 1. A case after Nephrectomy for Essential Hæmaturia. A woman, aged 35 years, with history of hæmaturia for two years, variable in amount but never completely absent. She was found to be bleeding from the left kidney only. This organ was exposed, slit open, but nothing was found. It was stitched up with through-and-through catgut sutures, and there has been a gradual cessation of hæmorrhage. 2. A lad after operation for Acute Obstruction due to a band, and also to tuberculosis of the termination of the ileum. The band was divided and a lateral anastomosis established between the ileum above the disease and the ascending colon, the diseased gut not being resected. The patient was now apparently well.

Mr. HENRY WADE showed: 1. A boy, aged 4½ years, three months after excision of the diaphysis of the ulna for Acute Infective Osteomyelitis. The operation was done 21 days after the onset of the disease, and primary union took place with complete osseous regeneration, massage and movement having been employed. 2. A boy, aged 4 years, one month after Nephropexy for Moveable Kidney. The child had gained a stone in weight and his intelligence had greatly improved.

Mr. D. P. D. WILKIE showed: 1. A male, aged 19 years, after operation for Perforated Duodenal Ulcer. He was very collapsed, and intravenous transfusion was done twice with no benefit. Oxygen gas was then led into the pouch of Douglas and allowed to bubble through the sero-pus there. Within three-quarters of an hour there was great improvement and the pulse became full and bounding. Oxygen was rapidly absorbed from the peritoneum and produced active intestinal peristalsis with well-marked leucocytosis. 2. A male, aged 36 years, after Implantation of the Omentum in the Abdominal Wall for Hepatic Cirrhosis with Ascites.

Mr. E. W. SCOTT CARMICHAEL exhibited: 1. A girl, aged 9 years, after operation for Tuberculous Disease of the Shaft of the Ulna and Tibia. Subperiosteal resection of the

diaphysis of both bones was done after Mr. Stiles's method. X ray photographs taken at two months' intervals showed the gradual growth of new diaphyses. 2. He demonstrated Oehsner's method of treating potential and acquired flat-foot by the application of oxide of zinc plaster strips.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 7th, Mr. W. Morley Willis, the President, being in the chair.—In opening a discussion on the Mortality of Appendicitis and How it can be Reduced, Mr. A. R. Anderson mentioned that during the last ten years there had been 973 operations for appendicitis performed at the Nottingham General Hospital with 89 deaths; of these 89 fatal cases in only one had pus been absent at the operation. While the number of operations at the hospital had yearly increased, the mortality had shown a yearly decrease. During the last 11 months there had been 138 operations with only seven deaths. This showed that the disease was now earlier recognised and the cases were sent up earlier for operation, with a corresponding increase in the safety of the operation. Ten years ago the routine treatment was first of all medical, and the surgeon was only called in to severe cases. Mr. Anderson then described what actually happens during an acute attack of appendicitis. Within 12 hours of the attack he had found the appendix crimson in colour and rigid and filled with muco-purulent fluid; a few hours later black and then greyish spots appeared in the wall of the organ, lymph became deposited on the neighbouring coils of intestines, and perforation might take place at any moment. The rapidity with which the symptoms might pass from bad to worse was amazing. Most operators had found pus present within 24 hours of the commencement of an attack. Defective drainage of the appendix, leading to stagnation of the contents and increase of the virulence of the organisms, was responsible for this rapid change of symptoms. The diagnosis might be confused with perforation of the intestinal canal elsewhere, but as a rule it was easy. Early operation, in his opinion, was the best and safest method of treatment. In cases, where from delay or otherwise an abscess had formed, the best treatment was to protect the peritoneal cavity with gauze and to empty the abscess and to find and remove the appendix. This latter point was still *sub judice*, but Mr. Anderson considered that it was wiser to remove the organ, as it had been known to lead to subsequent trouble if left. Septic general peritonitis accounted for 75 per cent. of the deaths from appendicitis. In these cases drains should be inserted in several positions and the patient kept propped up in bed and continous saline infusion administered. But the patients should not arrive at this serious condition, because they should be operated upon in the acute and early catarrhal stages. If this was done the mortality would immediately decrease.—Mr. R. G. Hogarth said that 80 per cent. of all cases of appendicitis, no matter what complications should arise, recover without operation. To reduce the mortality, the diagnosis and technique of the operation should be improved. He himself had mistaken for appendicitis cases of acute suppuration of the gall-bladder, parametritis, and tubal trouble in the left side. In children, too, the diagnosis was often difficult. Morphia was to be avoided and the pulse carefully watched. The "quiet interval," due to perforation of the appendix, was very dangerous, as it led to a feeling of false security.—Dr. C. H. Cattle said that many patients had safely got through three or four attacks of appendicitis. Where these attacks became so frequent as to incapacitate the patient, he advised operation. One never knew when a mild case would become serious, and therefore he advised operation if the symptoms did not improve after 24 hours.—Mr. K. Black advised operation where the symptoms persisted after 48 hours. Operations were free from mortality in the early cases; but it was so difficult for the surgeon to get hold of these cases. He had had the opportunity of watching 400 operations for acute appendicitis performed by various eminent surgeons at four large hospitals; and he observed that the mortality varied greatly with different surgeons. If the operation was properly performed in the early cases the mortality should be *nil*.—Dr. W. T. Rowe related a case of perforative appendicitis where the pulse did not rise above 72 per minute, but during the convalescence of the patient it was found that the normal pulse-rate was 56.—Mr. A. R. Tweedie did not advocate the removal of the appendix in cases of peri-appendicular abscess.—Mr. T. B. Gilbart-Smith gave morphia in those cases where the pain was acute and the signs were not clear.—The President recommended immediate and early operation where possible. In localised abscesses of several days' duration he preferred simply to drain the cavity and to leave the appendix alone. It was impossible to foretell whether a case would run a mild course or not, and he advised operation, leaving the responsibility of a refusal with the friends. In doubtful cases tenderness and rigidity were most important diagnostic signs.

OXFORD MEDICAL SOCIETY.—A meeting of this society was held in the Radcliffe Infirmary on Dec. 9th, Mr. R. H. A. Whitelocke, the President, being in the chair.—Mr. E. C. Bevers showed: 1. A woman, who for several years had suffered from a large Ventral Hernia, which had been cured by the implantation of a wire filigree. 2. A man, aged 60 years, whose large Irreducible Inguinal Hernia had been successfully treated by McGavin's double filigree operation. The method of inserting the filigrees in each case was demonstrated. Mr. Bevers advocated the use of a wire filigree in those cases of ventral hernia which were of large size and when the muscles had undergone such wide separation that to bring them together and overlap them would necessitate a severe operation, accompanied by shock and an undue increase in the intra-abdominal pressure. The final result in such cases without filigree was always doubtful. With a wire filigree a firm unyielding plaque was formed which could neither stretch nor bulge, and appeared to be the most rational method of closing a gap in the abdominal wall. In inguinal hernia the operation was indicated when the rings were large and the inguinal canal practically non-existent, due to atrophy of the muscles. The double filigree method would here give a good result, and, as McGavin stated, would bring all varieties of hernia within the reach of the surgeon.—Mr. A. P. Dodds-Parker showed a Tumour which he had removed from the abdomen of a woman. It consisted of a cyst the size of a large cocoanut firmly attached to the convex surface of the spleen. The spleen had to be removed with the tumour. Clinically the tumour had been freely moveable in the abdomen, but no certain diagnosis of its anatomical relations had been possible previous to the operation. The interior of the cyst contained a thickish jelly in which no evidence of its origin could be seen microscopically. Sections of the wall showed that it consisted of granulation tissue, and by none of the ordinary methods of examination was any evidence forthcoming that it was caused either by a parasite or by a bacterium.—Dr. A. S. GIBSON demonstrated a heart which showed Aortic, Mitral and Tricuspid Stenosis due to old-standing rheumatic lesions. The patient in the wards had shown the ordinary features of severe heart failure of the right side.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Dec. 7th, Mr. E. Stanmore Bishop, the President, being in the chair.—Dr. C. P. Lapage read a paper on the Diagnosis and Treatment of Malnutrition in Infancy. The causes of malnutrition in infancy were enumerated and discussed, attention being called to general diseases not especially connected with the digestive system and to rarer conditions, such as mongolism and congenital heart disease. Tuberculosis, though not uncommon in infancy, must not be diagnosed without definite evidence, the von Pirquet skin reaction and the examination of the sputum being important. The treatment of the majority of the cases consisted of exact and scientific methods in infant feeding, the percentage method being most valuable if not carried to unnecessary elaboration. The value of lavage and gavage in suitable cases is very great, especially when there is a tendency to spasmodic contractions of the stomach. Infusion was another therapeutic measure which often had striking results, especially in those cases suffering from great loss of fluid. Tuberculosis and other general diseases should be suitably treated and the prognosis of tuberculosis in infancy was by no means hopeless.—Mr. A. A. Bradburne read a paper on the Early Diagnosis and Treatment of "Simple" Glaucoma. He laid emphasis on the importance of the disease and its early recognition. He discussed the effects of hypertension and described the symptoms which such gave rise to, pointing out that these two

combined to afford the most valuable evidence in the early stages. Mr. Bradburne referred to the difficulties associated with the treatment of these cases. He advocated a modification of the ordinary disfiguring operation of iridectomy in selected cases. The modification, he considered, lessened the reactionary leucocytic infiltration—which tended to block up the already inefficient excretory channels and ultimately to seal up the iridectomy wound; it also permitted early massage, the latter being necessary in that cases of "simple glaucoma" did not, as was the case with acute and chronic forms, possess the tendency to hypertension which would assist maintenance of the patency of the wound.

Reviews and Notices of Books.

A Manual of Operative Surgery. By Sir FREDERICK TREVES, Bart., G.C.V.O., C.B., LL D., F.R.C.S. Eng., Sergeant Surgeon to H.M. the King, Surgeon-in-Ordinary to H.R H. the Prince of Wales, Consulting Surgeon to the London Hospital; and JONATHAN HUTCHINSON, F.R.C.S. Eng., Surgeon to, and Lecturer of Surgery at, the London Hospital, formerly Examiner in Surgery, Royal Army Medical Department. Third edition. With new coloured plates and many new illustrations in the text. In two volumes. Vol. I., pp. 775; Vol. II., pp. 821. London: Cassell and Company, Limited. 1910. Price 36*s.* net.

THE chief characteristic of the earlier editions of Sir Frederick Treves's "Operative Surgery" was that the work was a faithful reflex of the personal opinions of its distinguished author, and an edition edited by another surgeon, must of necessity fail to preserve this special quality. But Mr. Jonathan Hutchinson occupies a position which fits him thoroughly for the revision of Sir Frederick Treves's work, for he also represents the teaching of the London Hospital, of which Sir Frederick Treves was an exponent. The second edition has been long out of print and we have before us now, not merely a reprint of the early issue with omissions supplied and redundancies removed, but what is to all intents and purposes a new book, retaining many of the virtues of the previous issues while conforming to modern progress.

The book commences with a chapter on general principles, in which is considered the condition of the patient as influencing the desirability of an operation. This is a matter which often does not receive the full attention it deserves. The attitude taken with regard to the costume of the operating surgeon is reasonable, inasmuch as there is not too much insistence upon unnecessary detail, while due regard is paid to asepsis. On the question of gloves the surgeon is the best judge of what should be done, and no general rule can be laid down as universally applicable. We find mentioned a fact which is too often forgotten—that at some important German clinics the use of rubber gloves has been abandoned in favour of cotton ones. The authors are a little sarcastic as to the great preparations made by some surgeons, and they tell us that they have heard of a surgeon who before driving to an operation always has his carriage wheels washed with ether and carbolic solution. The description of the operating theatre and its fittings is all that could be wished, and the account of the instruments contains numerous illustrations. In the description of ligature material and suture material we think attention should have been drawn to the fact that many surgeons never employ any other material than catgut for a ligature or suture that has not to be removed.

The importance nowadays of operations on the abdomen is shown by the fact that the surgery of the abdomen comes first and occupies practically the remainder of the first volume. A general description is given of abdominal section, and we find an account of the value of the Fowler position in cases of septic peritonitis, but we have been unable to discover any reference to the value of Murphy's method of irrigation of the rectum with saline solution. Great stress is laid on the counting of instruments, pads, and sponges used in abdominal operations; it is surely far safer not to put anything entirely within the abdominal cavity; every instrument placed within the abdomen can usually have attached to it tape or gauze which would remain outside the wound. Cases have been recorded in which foreign bodies have been left in the abdomen in spite of counting. We thoroughly agree with the authors when they say that the simplest and most efficacious measure in the treatment of flatulent distension is to turn the patient on one side for a time. Many surgeons do not seem to realise the great increase of comfort which a change of position gives to a patient after abdominal section, and we fail to see that any harm can accrue from it.

In speaking of the results of cholecystotomy, Kehr is quoted as having operated on 397 cases of gall-stone, and the source of the quotation is dated 1898. Kehr's operations are very much more numerous than that, for he has now got well beyond his thousandth case, and a more recent reference should have been given. Our opinion on the value of pyloroplasty fully agrees with that expressed in this volume, and that is that though the method is ingenious and theoretically should give a very definite enlargement of the opening, practically it fails. The authors tell us that for suture of the intestine Dupuytren's continuous suture takes less time than Lembert's and is equally efficacious, a view that will be generally taken. We are glad to see that in the account of inguinal colotomy the credit of introducing the operation into this country and of several improvements in the method of its performance is given to Mr. H. A. Reeves. A modified Bassini operation is recommended for the radical cure of inguinal hernia, and for the buried stitches kangaroo tendon is advised. We think that the authors have done well to include chapters on ovariotomy, hysterectomy, and ruptured perineum. We are glad to see that McGill receives the credit which is his due for devising the operation of suprapubic prostatectomy, and that to Freyer is rightly ascribed the advocacy of enucleation of the entire prostate in preference to any partial operation.

The second volume commences with the surgery of the head, and we may specially refer to a good description of the operation for removal of the Gasserian ganglion. It is surely unnecessary in a modern text-book of operative surgery even to mention the use of the ligature and of the écraseur in the removal of the tongue for malignant disease. We are indeed told, in the chapter on excision of the tongue, that these methods are now quite obsolete, but nowadays they do not even require mentioning. The operation recommended for removal of the tongue includes preliminary ligaturing of the lingual arteries and the dissection of the groups of lymphatic glands in the submaxillary region and those lying over the jugular vein; at the same time the tongue is removed. The division of the operation into two stages is considered to be unnecessary. The discussion on the choice of operation for removal of the tongue is extremely good. The surgery of the breast is well described, though perhaps a little briefly. The operations on vessels and amputations need no special comment. For disarticulation of the hip-joint the anterior racket incision is preferred, and the operations on bones and joints and on tendons conclude the work.

We are thoroughly impressed with the excellent character of the whole book. There are undoubtedly many points in which individual opinion would not coincide with the procedure advocated by the authors, but the views of the authors throughout the book are wise, temperate, and founded on great personal experience. It should be added that the coloured illustrations representing the anatomy

of various parts of the body are excellent. Most of these have been based on dissections in the Medical College of the London Hospital or at the Royal College of Surgeons of England, and we have never seen illustrations of this kind which surpass them.

Radio-Activity: A Brief Guide to its Use in General and Specialist Practice. By GUY STEPHEN, D.P.H. Lond.; Officier de Santé (France). London: Van Alexander and Co. 1910. Pp. 44. Price 1*s.*

THE author in his foreword states that he has merely endeavoured to compile a fair summary of what is at present known clinically and scientifically of a method of treatment still in the growing stage. It may be said at once that he has succeeded admirably in his object. The vast amount of literature dealing with radium-therapy already in existence—and by far the greater part of it is written in a foreign language—renders it difficult for a busy medical man seeking information on that subject to obtain precisely what he requires, save at the expenditure of much time and trouble. To such persons this little treatise may confidently appeal.

The author very wisely concerns himself but little with the chemistry and physics of radium; he formulates briefly and in the clearest possible manner the fundamental points which must be grasped by would-be workers with radium, and relies upon their supplementing this knowledge by reference to any of the large text-books on radio-activity should occasion arise. He describes the various forms of apparatus employed for the application of radium, and remarks that the use of radium salts loosely contained in a glass tube is now falling into abeyance, an opinion with which we are in complete accord, such a procedure being both unscientific and inaccurate and ill adapted to procure satisfactory results. For the measurement of the initial radio-activity he adopts the scale laid down by the French school, 1 centigramme of pure radium bromide evolving 2,000,000 units of radio-activity as compared with the 1 unit evolved by the same quantity of pure uranium oxide. He points out that in most instances when used therapeutically the pure radium salt is diluted in varying proportions with barium or some other inert element, and that thus by dilutions of 1 in 2, 1 in 4, or 1 in 10, initial radio-activities of 1,000,000, 500,000, or 200,000 are easily and correctly obtained.

In dealing with the radio-therapeutic principles he gives a short but sufficient account of the histological researches on radiumised tissues which have been carried out by Barcat and Dominici, and which showed that, speaking generally, the first effect of the radium rays was to cause stimulation of growth of the cells of normal tissues, but to produce a marked lessening of vitality of the neoplasic cells of tumours, which often proceeded to definite necrobiosis. This is the so-called "selective action" of radium as described by Wickham and Degrais. With increased dosage or prolonged application of radium the stimulative action of the rays on normal cells is converted into a destructive one; and it is mainly to the proper appreciation of these principles and the correct selection and combination of radium apparatus and filtering screens that all successful radium therapy is due. In dealing with the somewhat technical subject of filtration the author describes the differing powers of filtration possessed by sheets of aluminium and lead, varying from 4/100th millimetre to 2 millimetres in thickness, and points out that the thinnest of these suffices to cut off all alpha and most soft beta rays, whilst a screen of 5/10th millimetre of lead will stop all alpha and nearly all the beta rays, leaving only the "ultra penetrating" radiation of Dominici. With regard to radium reactions, he emphasises the fact that the application of radium is absolutely painless, even analgesic. We think he might have laid a little more stress upon the latter point, as in many instances, notably in malignant disease, the relief obtained by radium applications is wonderful. He shows that there is no hard-and-fast line between destructive and reconstructive action, but that the two processes shade insensibly into one another; and also gives a word of caution as to the relative susceptibility of various tissues, of which full note must be taken in determining the dosage to be employed. Turning to cases which offer the best hope of successful radio-therapy, he details those in which the most favourable results have been obtained, and which are for the most part definite lesions or chronic inflammations of the skin.

Referring to the very important and much discussed question of the treatment of malignant growths he is of opinion that the results vary chiefly in accordance with the depths of the tissue involved, and alludes to the difficulty of successfully dealing with epitheliomata of the mucous surfaces, which are invariably more resistant to treatment than those affecting a glabrous surface. We fully agree with his view that radium should not replace the surgeon's knife in the treatment of all operable cases of malignant disease, but should be used as an adjunct to it. It may often be advantageously employed before an operation to induce retrogressive changes in the growth, or after the operation to destroy possible small deep-seated and imperceptible foci.

The last chapter is devoted to a consideration of the therapeutic use of radio-active earths, mud-baths, &c. This mode of treatment has so far obtained no footing in the British Isles, but is greatly in vogue at some of the continental spas and in Paris. The technique is simple and harmless, and good results in the treatment of rheumatism and allied conditions are claimed for it, but much yet remains to be done before a positive pronouncement can be made thereon.

In conclusion, we congratulate the author on an interesting little treatise, which should be on the bookshelf of every practitioner who desires to acquaint himself with the present position and future possibilities of radium therapy.

Meteorology, Practical and Applied. By Sir JOHN W. MOORE, M.A., M.D.Dub., D.P.H., D.Sc. Oxon. (Honoris Causâ), F.R.C.P. Irel. Second revised and enlarged edition. London: Rebman, Limited. 1910. Pp. 492. Price 10*s.* 6*d.* net.

THE last 10 years have seen very great advances in meteorological science, arising partly out of the increasing scientific interest taken in the subject and partly from an increasing conviction of its importance in industry and in health. It is open to everybody to study meteorology, for it involves no elaborate machinery, no specially equipped laboratory, no complicated apparatus, and yet there are few who take advantage of these facts. A few people "tap the glass" occasionally, and make perhaps in addition a note of the variations of temperature, the only significance of which to them is the question of whether it is going to be a fine or wet day. The direction of the wind, the kind of cloud that hangs in the sky, the hygrometric indications, the electrical storm, are regarded as interesting natural phenomena, the meaning and significance of which, however, are rarely seriously studied. We may hope for better things, perhaps, when the subject is discussed more widely, and amongst the observers doing excellent work in this direction is Sir John Moore, the author of the interesting and attractive volume before us. No intelligent person will start reading a chapter in this book casually without going on seriously with it. The interest once started continues. Sir John Moore has been at great pains to make the second edition of his book "reflect to an adequate extent the advances which have been achieved." He has drawn freely on the works written by well-known authorities. He gives references to the

journals which contain the original account of researches in meteorology, and the result is an admirable and up-to-date collection of the world's work on the subject. It is an advantage that he has written from the point of view of the amateur observer, for his writing appeals to the reader who requires technical and scientific terms explained. His object has been to convey a clear idea of the science of meteorology to the person of ordinary intelligence and education, who for some reason or other has not previously had his attention attracted to the subject, in spite of the notorious willingness of all the inhabitants of this country to talk about the weather. Mainly Sir John Moore writes as a physician, but the application of the study of weather to questions of health he has reserved for the closing chapters. He starts with a brief introduction, partly historic and partly an emphasis of the importance of the subject, which is succeeded by an account of the methods employed in practical meteorology, the uses of the barometer, thermometer, hygrometer, anemometer, electroscope, kites, and so forth. Then follows an engaging section on climate and weather, and, lastly, in Part IV., three chapters on the influence of season and of weather on disease. The book is well and usefully illustrated and is full of the most interesting and entertaining material.

The Flora of Algeria. By ALFRED S. GUBB, M.D. Paris. London: Baillière, Tindall, and Cox. Price 5*s*.

BOTANY has ever been a favourite pastime with medical men provided with adequate leisure, and the exotic vegetation of Algeria is well calculated to stimulate into activity any latent taste of the kind. This comely volume is a photographic album of trees, plants, and flowers met with in that favoured clime, not necessarily indigenous to the soil but which have been acclimatised. The author is careful to disclaim any scientific pretensions for his work, and contents himself with giving a brief description of each plant in order to facilitate identification. Naturally, the first thing the visitor to Algeria asks is the name of the various vegetable eccentricities that attract his attention, and we can quite believe from personal experience that it is the exception to meet with trustworthy informants, the knowledge even of professional gardeners being limited in most instances to the score or so of flowers which they are accustomed to handle. On the whole, we may congratulate the author on the success of his photographic efforts, which are well produced on art paper. In any future edition, however, he would probably be well advised to amplify his descriptions, which, if anything, err on the side of brevity, and if he could see his way to give his readers a leaf index they would assuredly be grateful for its assistance in the pursuit of knowledge.

British Rainfall, 1909. By H. R. MILL, D.Sc. London: Edward Stanford. 1910. Pp. 120 + 308. Price 10*s*.

IN this, the forty-ninth annual volume, Dr. Mill gives an account of the organisation started by the late Mr. G. J. Symons, carried on by him until his death in 1900, and since then under Dr. Mill's own control. Nine other observers are now associated with him as trustees in the British Rainfall Organisation. The total number of complete records furnished during the year 1909 was 4681, an increase of 143 over 1908. Dr. Mill shares in Mr. Symons's strong belief that freedom from the conventional red-tape of official procedure is essential for the success of the undertaking; with this view, no doubt, very many scientific observers will agree. Mr. Gethin Jones contributes an article on the spot in England and Wales where snow lies latest; this is in a gully (not marked in the Ordnance maps) at an elevation of 3000 feet, lying 1200 yards N.N.E. of Carnedd Llewelyn in the Snowdon range, where snow lay until the end of June in the present year (1910), as shown in photographs reproduced in this volume. The outstanding feature in the rainfall for 1909 was the large number of hours' fall recorded in all parts of the country: at Camden-square the figure was the highest (576·5 hours), except in 1903, during 29 years. The average fall for England and Wales was 35·30 inches, being 4 per cent. above the average of 29 years; for Scotland it was 45·59 inches (4 per cent. below average); and for Ireland 38·13 inches (10 per cent. below average). The wettest place in England and Wales was The Stye, Cumberland (176·30 inches); in Scotland it was Loch Quoich (151·10 inches); and in Ireland, Killybegs, Donegal (78·71 inches). The least rainfall was registered at Fortrose, Ross (19·45 inches). The value of the labour of Dr. Mill and his coadjutors in British climatology can hardly be over-estimated, though we fear that it is quite true, as he says, that "at present the Local Government Board has no idea of the vast importance of the accumulated rainfall data at the service of the country."

LIBRARY TABLE.

Sanitary Law in Question and Answer. By CHARLES PORTER, M.D. Edin., Barrister-at-law. London: Longmans, Green and Co. 1910. Pp. 150. Price 3*s*. 6*d*.—In very small compass and without any padding Dr. Porter has provided the student of public health with all that he need know in regard to sanitary law at this present date. The various Public Health Acts are summarised and their provisions and intentions expressed in plain English; in the second part the principal allied Acts are similarly dealt with. The work is strictly up to date, last year's Housing and Town Planning Act being concisely but adequately described. The form of question and answer is not much in favour nowadays for a text-book, but for such a subject as sanitary law it appears to be quite suitable. This is a convenient manual, and the author's experience as medical officer for a metropolitan borough guarantees that the information is to be relied on.

First Aid to the Child. By D. HASTINGS YOUNG, M.B., M.S. London: G. Routledge and Sons, Limited. Pp. 317. Price 3*s*. 6*d*.—The object of this book is twofold: to teach mothers and nurses how to maintain the health of infants and young children, and also to serve as a "first aid" guide in the treatment of their diseases. The first section deals with the feeding of infants, the second with their diseases. The book is written in simple language, and though not of striking originality would be useful in cases where a medical attendant is not available. As in most books of the kind, the writer seems to have found it difficult to determine how much medical knowledge should be assumed in the reader and how much technical instruction should be given to persons presumably unacquainted with the groundwork of medical science. The instructions as to feeding are carefully given and the preparation of "humanised" milk is clearly described. The writer seems to have a prejudice against pasteurisation of cows' milk, which is barely mentioned; neither are dried milks noticed. Mumps is described as a disease of the mouth, and no precautions against infection are mentioned. Not everyone will agree with the statement that in connexion with post-nasal growths hearing is but rarely affected. Speaking of asthma it is rightly said that late suppers should be avoided; but such an injunction applies rather to adults. Diphtheria is said to be supposed to arise originally from defective drainage; no mention is made of milk as a vehicle for infection. Chorea is barely named, and not described, nor its importance in connexion with the rheumatic diathesis appreciated. The subjects of ringworm and parasites are also very lightly touched on. On the whole, although there is

useful information in the volume, it does not convey the idea of being the outcome of any large practical experience.

An Elementary Course of Food Testing. By B. A. BURRELL, F.I.C., Lecturer on Food and its Adulteration, Central School of Commerce, Leeds. London: Baillière, Tindall, and Cox. 1910. Pp. 92. Price 2*s.* 6*d.* net.—This is a very short and simple introduction to the chemical analysis and microscopic examination of some of the commoner food substances, compiled for the use of a class formed for the study of food and its adulterations. It is written simply, and makes no pretence to originality. Short and elementary as it is, there are some omissions that one is surprised to find. The origin of the metre is mentioned, but not the reason for adopting the weight of 1 cubic centimetre of water at 4° C. as the unit of weight. A few illustrations of starch grains, &c., are given, but very little use is made of the microscope. In a book published in 1910 we should expect to find the nitrogenous principles of food called proteins and not "albuminoids," this term having been practically abandoned by scientific chemists. Red litmus paper, again, is not the best indicator for alkalies, while turmeric is not mentioned.

Livingstone College Year Book, 1910. London: Livingstone College, Leyton, E. Pp. 128. Price 6*d.*—This account of excellent work in the medical training of missionaries records a slight falling off in the number of students at the college during the past year, which we trust is only temporary. An account is also given of the work in various parts of the world carried out by past students of the College, together with some notes on recent advances in tropical medicine. As to the value of the training afforded at the College there can be no question; those who pass through the course do not become "medical missionaries," nor do they assume to themselves the status of qualified medical practitioners. But they receive sufficient medical training and instruction in tropical hygiene to enable them to look after their own health, and to be of great use to the people with whom their lot is cast "in places where they themselves, or those about them, may sicken and die from curable diseases before the doctor could be summoned, even supposing he could leave his post and come."

BRITISH MEDICAL BENEVOLENT FUND

AT the November meeting of the committee 28 most distressing cases were considered and grants amounting to £300 made to 27 of the applicants. So few contributions have been received during the last few months that to do this it was necessary to draw upon, and indeed nearly exhaust, a small fund which has been carefully reserved for such an emergency. The committee therefore urgently appeals for help to enable them to deal with the numerous applications which are certain to be received at the next few meetings. Appended are particulars of the cases relieved:—

M.D. Lond., aged 43 years. After holding responsible resident posts in this country went abroad and worked up an excellent practice, but two years ago had an attack of hemiplegia and is now quite incapacitated. Two children, aged 10 and 9, at present being looked after by a relation. Has a small income, but it is insufficient for present unavoidable expenses. Voted £6.

Wife, aged 61 years, of L.F.P.S. Glasg., who is at present acting as ship's surgeon. Applicant lets lodgings, but in her husband's absence has unavoidably got a little behind with the rent. Voted £2.

Widow, aged 46 years, of M.R.C.S. Eng. Quite unprovided for at death of husband nearly 20 years ago, and finds great difficulty in supporting herself as a maternity nurse. Relieved four times, £46. Voted £12 conditionally.

Widow, aged 53 years, of L.R.C.P., L.R.C.S. Edin. Quite unprovided for at recent death of husband, and the small sum obtained for the death vacancy was swallowed up by debts. Endeavours to support herself by taking boarders, but at present has only one paying a small weekly sum. Voted £10.

Widow, aged 40 years, of M.D. Durh. Has been acting as a companion, but is temporarily in a state of health which necessitates a complete rest. Voted £12.

Widow, aged 62 years, of M.R.C.S. Dependent on an annuity of £10 and 5*s.* a week from an old age pension. Children unable to help. Voted £6.

L.R.C.P. Edin., aged 52 years. Used to have a fair practice in London, but for the last five or six years has been in very bad health and is now quite destitute. Hopes shortly to obtain a ship's surgeoncy. Voted £5.

Widow, aged 74 years, of M.D. Lond. Entirely dependent on two small annuities and requires help to obtain the small comforts necessitated by her age. Relieved five times, £31. Voted £5.

Daughter, aged 60 years, of late L.S.A. No income; tries to support herself by letting lodgings, but has been incapacitated for a few months as the result of an accident. Relieved twice, £24. Voted £12.

Wife, aged 65 years, of L.R.C.P. Was deserted seven years ago through no fault of her own, and is entirely dependent on this Fund and the Distressed Gentlefolks' Aid Association. Suffers from chronic bronchitis and is therefore unable to support herself. Relieved three times, £36. Voted £12.

L.R.C.P. Edin., aged 54 years. Has been quite incapacitated for several years by spastic paralysis and is dependent on an aged mother who can ill afford to help. Relieved six times, £72. Voted £12.

Widow, aged 53 years, of M.R.C.S., L.S.A. No income and health too feeble to permit of any regular work. No children. Relieved six times, £68. Voted £12.

Widow, aged 50 years, of L.S.A. No income and dependent on this Fund and a son earning only 17*s.* a week. Is blind in one eye and nearly so in the other. Health very feeble. Relieved six times, £70. Voted £18.

Daughters, aged 58 and 53 years, of late M.R.C.S. Endeavour to support themselves by needlework, but are in feeble health. Relieved six times, £74. Voted £20.

Daughters, aged 60 and 51 years, of late M.R.C.S. Live in a small house which they own and take boarders, but have had a very bad season. Relieved once, £10. Voted £18.

Daughter, aged 59 years, of late M.D. Lond. No income; lets lodgings. Relieved 27 times, £202. Voted £6.

L.R.C.P., L.R.C.S. Irel., aged 64 years. Was obliged to give up a practice in the North of London on account of ill-health, and is now quite incapacitated and without means; slight help from a sister-in-law. Relieved once, £18. Voted £18.

Widow, aged 62 years, of late M.R.C.S. Income £12 a year; children only able to give very slight help. Relieved once, £12. Voted £12.

Widow, aged 65 years, of M.R.C.S., L.R.C.P. Supported herself for some years as companion, &c., but is now only able to earn a few shillings a week by needlework. Relieved once, £12. Voted £12.

Widow, aged 65 years, of M.R.C.S., L.S.A. Supported herself for 24 years, but is now unable to obtain a suitable post. Relieved twice, £24. Voted £12.

Daughter, aged 58 years, of late L.R.C.P. No income; very deaf and otherwise unfit for any employment; dependent on a sister who has to earn her living. Relieved five times, £56. Voted £12.

Daughter, aged 63 years, of late M.R.C.S. Is not physically strong and gives her services as housekeeper in return for a home but receives no salary. Relieved twice, £24. Voted £12.

Daughters, aged 46 and 38 years, of L.S.A. Both physically incapable of earning a living; the elder has recently obtained a pension of £21 per annum; the younger is entirely dependent on her mother whose income is very small. Relieved six times, £72. Voted £6.

Widow, aged 69 years, of L.R.C.P. Edin. No income; children do not help; eyesight failing. Relieved three times, £36. Voted £12.

Widow, aged 61 years, of late M.R.C.S. Health very indifferent and only income 7*s.* a week, contributed by her sons. Relieved twelve times, £135. Voted £12.

Daughter, aged 56 years, of late L.S.A. Eyesight defective and chronic ill-health, which makes any continuous employment impossible; slight help from friends. Relieved nine times, £92. Voted £12.

Daughter, aged 52 years, of late L.R.C.P. Nursed both mother and father during illnesses which lasted many years, and is now without any means and unfitted to earn a livelihood. Relieved twice, £24. Voted £12.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

LITERARY INTELLIGENCE.—Messrs. Rebman, Limited, have in the press for early publication the authorised translation of "Die Experimentelle Chemotherapie der Spirillosen, &c.," by Ehrlich and Hata, the German edition of which has just appeared. The same publishers will also publish shortly "The Treatment of Syphilis with Dioxy-Diamido-Arseno-Benzol" (Ehrlich-Hata "606") by Wechselmann.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—The following papers were read before the Royal Society on Dec. 8th by members of the staff of the Liverpool School of Tropical Medicine, viz.:—1. Some Enumerative Studies on Malarial Fever, by Major Ronald Ross, F.R.S., and David Thomson, M.B., Ch.B., D.P.H. 2. Experiments on the Treatment of Animals Infected with Trypanosomes by means of Atoxyl, Vaccines, Cold, X Rays, and Leucocytic Extract: Enumerative Methods employed, by Major Ronald Ross and J. G. Thomson, M.A., M.B., Ch.B. 3. The Life History of Trypanosoma Gambiense and Trypanosoma Rhodesiense as seen in Rats and Guinea-pigs, by H. B. Fantham, D.Sc., B.A. 4. Enumerative Studies on Trypanosoma Gambiense and Trypanosoma Rhodesiense in Rats, Guinea-pigs, and Rabbits, Periodic Variations Disclosed, by H. B. Fantham, D.Sc., B.A., and J. G. Thomson, M.B., Ch.B. 5. A Case of Sleeping Sickness studied by Precise Enumerative Methods: Further Observations, by Major Ronald Ross, F.R.S., and David Thomson, M.B., Ch.B., D.P.H. 6. New Inventions.

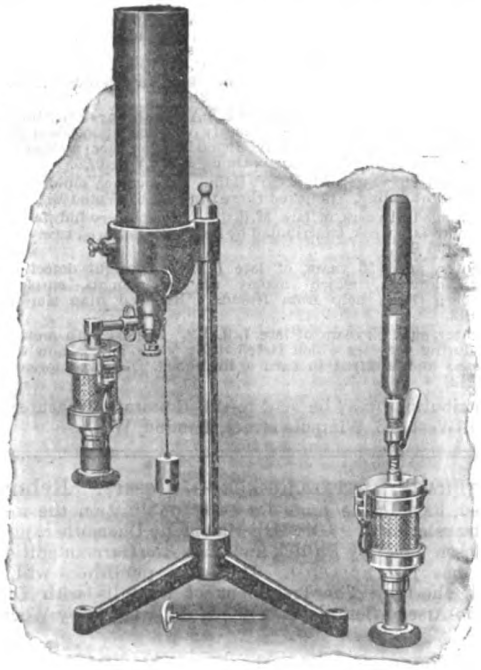
THE "PRANA" CARBON DIOXIDE SNOW APPARATUS.

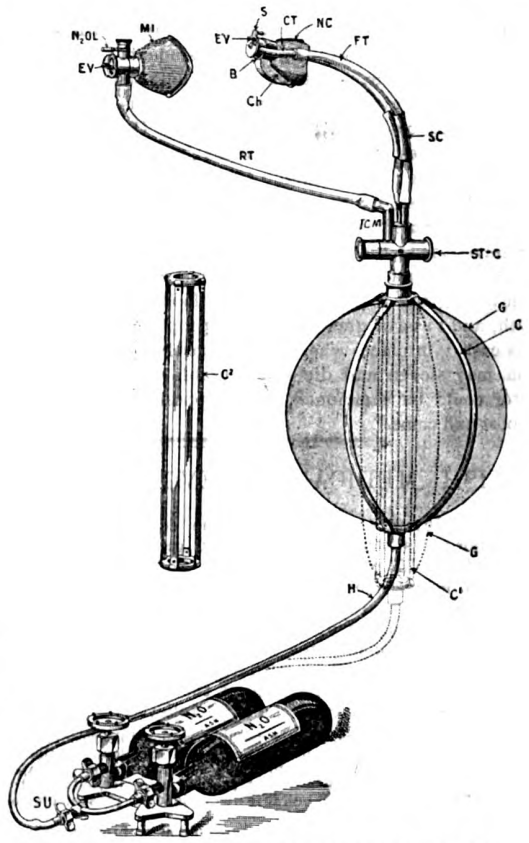
THIS apparatus is designed for producing the new freezing caustic CO_2, in the treatment of nævi, lupus, lupus erythematosus, lupus vulgaris, warts, moles, and so on. The method of treatment was described in a paper by Dr. Reginald Morton read before the Electro-Therapeutical Section of the Royal Society of Medicine on Nov. 19th, 1909, which was published in THE LANCET of Dec. 4th, 1909 (p. 1658). A subsequent paper by the same author appeared in THE LANCET of May 7th, 1910 (p. 1268). The "Prana" apparatus produces a convenient and effective pencil of carbonic acid snow with a minimum of trouble. It consists of a steel cylinder containing liquid CO_2 to which is attached a specially constructed metal box in which the CO_2 as it escapes condenses to snow. The snow obtained is ultimately compressed in a kind of stamp-mill or mould from which it emerges as a firm stick or pencil. The process is very simple and expeditious. In the accompanying illustration the apparatus on the left is for hospital use, and that on



the right is portable and convenient for general practice The temperature of the frozen gas is −79° C. A constantly cold solid of definite shape is obviously more convenient to use than a liquid refrigerant. The pencil of solid CO_2 enables, for example, as much pressure to be applied as is wanted, and thus freezes the tissues to any desired depth up to a reasonable limit. There is a gradual escape of gas from the pencil when it is applied, so that a fresh surface is constantly being presented. The action of the pencil is easily under control and can be readily localised, the extreme degree of the cold enabling its devitalising action to extend rapidly to the intended depth without risk of injuring deeper or adjacent parts. For shallow growths, it is said that an average period of 40 seconds suffices for the required depth of destruction, while deeper structures such as a thickly crusted wart require a longer application. Beyond a trifling smarting during the application, and some pain as the parts recover their normal temperature, there is no serious inconvenience to the patient. The apparatus marks a valuable and important development in dermatological practice. We are indebted to Aerators, Limited, of Upper Edmonton, London, N., for an inspection of the types illustrated above.

A NASAL INHALER FOR THE CONTINUOUS ADMINISTRATION OF NITROUS OXIDE.

SINCE the introduction in 1898 of the nasal method for administering nitrous oxide several forms of inhalers have been introduced and as many methods evolved in their employment. This would seem to indicate that no one form of inhaler is capable of satisfying the demands of every anæsthetist. The apparatus figured below allows the induction of anæsthesia by the two chief methods at present employed, and by a simple mechanism of throwing out of action certain valves the conditions favoured by other administrators can be obtained. The self-retention of the nasal inhaler, the absence of rubber pads, and a regulating



Combined mouth cover and inhaler.—MI, Mouth cover. N_2OL, Nitrous oxide lever. EV, Expiratory valve. RT, Rubber tubing. ICM, Inhaler connexion mount. Nose-piece, &c.—EV, Expiratory valve. B, Body. Pluralists in Medical Posts.

THERE was a time when it was quite common—in fact, so common that it would have been but little exaggeration to describe it as the rule—for several posts in the Church to be held by one man. The same incumbent was dean of one place, rector of another, and vicar of a third, and these three posts were held by him when other men, probably equally suitable for the work, were without any benefice. With duties so numerous, with posts often situated far apart, even in different counties or in different sections of the kingdom, it was physically impossible for the holder to discharge fully and completely the charges he had undertaken, but a few years ago both the theoretical and practical difficulties were ignored. So serious, however, at last did the practice of pluralism in the Church become that it was considered necessary to institute restrictive legislation, and now it is illegal for a Clerk in Holy Orders to hold several benefices unless they are small and situated within a short distance of each other. The subject of pluralism has of recent years become the subject of debate in the medical world. In a recent letter from our Vienna correspondent it was mentioned that the practice of holding several hospital appointments had been found in that city to act unfairly towards many of the junior members of the profession. Our correspondent wrote that it was not uncommon for a professor to hold the position of consultant in some special department at four or five different institutions, while many *privat docenten* were unable to obtain any post. It is certain that this difficulty is not confined to Vienna. In the British Isles it is quite usual to find one physician or one surgeon holding several distinct posts at different institutions, and in this way doing much to block the junior members of the profession in their advance, and last week we published the new rules dealing with this subject which have been recently considered and confirmed at a meeting of the subscribers to the General Infirmary at Leeds. These rules provide that in five years from Jan. 1st, 1910, pluralism will cease to exist among the members of the full honorary medical staff, who will be permitted only to hold the infirmary appointment. From the same date onwards the assistant medical staff will only be allowed to hold one other hospital appointment in addition to the infirmary appointment. The rules display very clearly the modern feeling towards pluralism in medical appointments, and are wise in their different treatment of the full and assistant staffs.

The same motive is not at work here as aforetime influenced the opposition to the pluralists in the Church. There the motive was frankly a fairer sharing of the pecuniary rewards derived from the several benefices. A large portion of the work of the pluralist was practically never done in person; for the most part it was entrusted to a junior member of the clerical profession at but a small percentage of the actual remuneration. In medicine the case is otherwise. The actual pecuniary benefit derived from the holding of any post is very small—in fact, in many cases it does not exist. There is no attempt made to transfer the work to a deputy; rather the holder of these many posts, rejoicing that he has so many, enjoys and performs the hard work which those posts entail. It cannot be denied that in many cases indirect benefit does accrue to the medical pluralist. The fulness of experience cannot fail to render his knowledge wider and more exact; some increase of reputation is also probable, and the increase in reputation will almost always result, when combined with the fulness of experience, in increase of practice. Still, the beneficial consequences are by no means certain, and we have known the energetic holder of multiple posts perform herculean tasks in conscientiously fulfilling numerous duties, and yet derive neither directly nor indirectly any pecuniary benefit therefrom. And it is not unusual to see the man whom over-strenuous effort has not rewarded in any way fall into a lifeless manner of discharging his too heavy responsibilities. We can well understand and sympathise with the desire to see as much as possible of the work in every branch of medicine; it betokens a zeal well suited for such a profession as medicine, but it may have consequences harmful to the zealot. When a man is in the first decade of professional life no amount of work appears to be too arduous, no hours seem too long for the furtherance of study, but as years go by the power to indulge in such feats diminishes. There is a natural unwillingness to resign work which was once a joy, and if such a resignation appears as a confession of advancing age it is obvious that the temptation to hold on to all becomes very strong. But it should be resisted. With all due justice to the conscientious pluralist, it is just possible that there may be a little hurry in his carrying out of the work, a little less care and attention being paid to it than would be paid if there had not been so much work to do. From this situation the rules which have been made recently with regard to pluralism at several of our large hospitals will serve to save a man in a dignified way.

We have spoken of the harm to the medical pluralist, but the harm to his younger brethren is just as important. At the present day the number of men who wish for hospital work is so large, that if several posts are held by one man many who may be just as intelligent, just as learned in that department of medicine, will fail to obtain any post at all. A post at some minor hospital, which may be of the slightest value to the man who has advanced far in his profession, may be of very great account in every way to his younger colleague. The boards of management of some of the more important hospitals already recognise that danger may attach to the holding of several hospital posts by the same man, and they reserve to themselves the right to require of men appointed to the medical staff of these hospitals that they should resign other posts if called upon to do so. Usually they look upon a post at a children's hospital

as not incompatible with due attention to the duties of staff officer to a general hospital, but as a rule they decline to allow a member of their staff to be also a member of the staff of another medical school, and they would certainly decline to allow any serious rearrangement of hospital hours so as to enable members of the staff to be elsewhere when they should be within the hospital walls. Our own view is that not more than one post at each of two hospitals should be held by the same man. These posts should give him ample opportunity for hospital work. They would provide him with all the experience he may need, they will require from him all the energy which he can reasonably be expected to devote to hospital work, and he will not be depriving a younger colleague of an opportunity of obtaining due advancement. It would be difficult for the medical profession as a whole to take any part in laying down rules for the carrying out of this arrangement, and the discretion in the matter must remain with the governing bodies of hospitals. We have seen that in Vienna a useful change has been brought about by the hospitals themselves, and we feel sure the hospitals in this country are quite capable of dealing with the position.

The Extension of Hospital Care.

THE first annual report has been issued of a charity entitled the Cicely Northcote Trust, under a scheme initiated last year in consequence of the trustees of the fund named having offered to devote it to the establishment of social work in connexion with the in-patients of St. Thomas's Hospital. The step thus taken tentatively for the benefit of the inmates of a particular institution, and submitted to public appreciation by the issuing of a first report, deserves attention as such, and also on account of the possible developments which may attend upon its success in the future. It may, indeed, prove to be the beginning of an important movement of a kind which has already made its usefulness felt in the United States, but which has not hitherto been organised with us in any widely extended or systematic manner. If we explain briefly what are the objects of the Cicely Northcote Trust and the methods by which it is sought to attain them, it will be seen that the matter is one worthy of the attention of all who desire to see our hospitals working with full efficiency to alleviate suffering among the poor, and exercising a beneficent influence not limited to the treatment, surgical or medical, administered in their wards. A document such as the report before us is not addressed to the medical profession, but to that wider public who supply for the contests waged in our hospitals against physical incapacity and death the sinews of the war, and who if they ever enter the hospitals do so as sympathetic onlookers only. It reminds these, or any who may in imagination put themselves in the position of such sympathetic onlookers, that in many instances the suffering of the hospital patient stricken down by disease or by accidental injury is not confined to the sensation of physical pain, severe though that may be. Doubt, fear, and anxiety augment bodily suffering by mental torment. There may be distracting uncertainty as to the future and as to the present fate of those left at home destitute, to face the situation arising from the incapacity of the worker. There may be the knowledge that when all that the hospital can do has been accomplished it must be rendered ineffective by the poverty, misery, and ignorance into the midst of which the patient knows that he is returning. This, by the way, is a knowledge which must affect others than the patients themselves with a feeling that all the care bestowed, so far as any lasting good is concerned, will perhaps be altogether wasted.

For some years social work among the out-patients has been carried on, so far as means have allowed, at St. Thomas's Hospital, and the same is now being tried under the auspices of the Cicely Northcote Trust in the case of the in-patients and of phthisical and obstetric cases under treatment in the out-patient department. In the case of the last the demand upon the resources of the Samaritan Fund has been too heavy to be met, and it was not considered that they were the patients for whose benefit it was intended. When the scope and objects of the proposed new work came to be considered it was felt that the best policy was to draw up an extensive programme and to start operations in a small way under all the headings included in it, allowing circumstances and increasing knowledge and experience to modify or augment the efforts made in any particular direction. It was resolved as a general plan, therefore, (1) to carry out a system of social service in connexion with the wards, including the assistance of in-patients and their families, but not the granting of surgical instruments or convalescent treatment already undertaken by the Samaritan Fund; (2) to undertake the care of all phthisical out-patients and to supervise their homes; and (3) to provide for the assistance of out-patients attending the obstetric department. In practice the endeavour is made to encourage thrift and independence, and to subsidise the efforts of those honestly endeavouring to help themselves, and to enable, as far as possible, the instructions of physicians and surgeons to be carried out. Aid is thus given to persons who have not hitherto come under the Poor-law, those already in receipt of parish relief being left to the care of the guardians. As can readily be supposed, the work attempted in a first, and consequently experimental, year, subject to the limitations of a restricted income, has not been extended throughout a large hospital. In certain wards where the trial has been made a "Northcote worker" has visited patients at regular days and hours in order to ascertain such details of their home lives and needs as they might be ready to impart. This has been done in combination with the ward sisters, and so far as the Northcote worker is concerned it is confined to the precincts of the hospital itself. Outside, where help appears to be wanted, the aid of the clergy, of the Invalid Children's Aid Association, of the Charity Organisation Society, and of similar institutions as well as that of sympathetic individual volunteers, is invoked, the home is visited, and its conditions are thoroughly inquired into, after which assistance is given or withheld in accordance with the needs of the case. These, of course,

vary widely both in nature and in the extent to which pecuniary or personal influences may be required for their alleviation. A little tactful persuasion may have to be applied in order that a workman's situation may be kept open for him until his recovery; a home may have to be visited in order to see that the children are being cared for during their mother's absence; material aid, instruction, and supervision may be wanted in order that a phthisical patient may carry out at home advice which the physician can give but cannot enforce. In a large number of obstetrical cases, besides such help and counsel as may be needed in order that the physical welfare of the patient may be protected, there is obviously an opportunity for the sympathetic adviser and friend almost unlimited in its extent and in the variety of its demands upon the helper's resources. It is only necessary, however, to indicate the nature of the work in order to point out that its extension must depend upon the number and zeal of those who are willing to assist and upon the resources which the generosity of the charitable may place at their disposal. It is not a question of regulating the almsgiving of a benevolent institution, and of increasing its power to bestow money upon the poor, but of distributing in the most practical way help which may take the form of money or of money's worth, but which may in other instances be equally effective for good without the expenditure of a shilling. It is the holding out of a helping hand which will be grasped gratefully for the sympathy and aid that it brings—a hand which will supplement and render complete the work of the hospital, but which the hospital cannot extend because its energies, and the funds which sustain them, have to be devoted to definite purposes of a particular and limited nature.

We observe that in a note preceding the Lady Almoner's report of the work of the Cicely Northcote Trust it is said that: "The work is increasing so rapidly now that if it is to progress, as it is hoped it may, it will be necessary to obtain a much larger income to meet the heavy working expenses and to engage further skilled and trained assistance. It is hoped that after the publication of this first annual report the work may be increased by donations and annual subscriptions being sent to the honorary secretary." We echo that hope in giving publicity to it, and shall watch with interest the progress of the trust named and the development of the effort which it represents to alleviate a form of misfortune which evokes our warm sympathy. Our hospitals open their doors to the poor when stricken down by disease or by injury, and, so far as it lies in their power, minimise by medical and surgical treatment the weight of the blow which disease or injury inflicts upon those whose health, and consequent ability to earn a living by their daily toil, are often their only assets. It is not possible for hospitals to carry the work further than the healing of the physical disability, but they may well become the source and centre of charitable endeavour to avert the otherwise inevitable consequences of incapacity from falling upon the patient and his or her dependents. They should thus be able to inspire and guide the operations of voluntary lay workers in the cause of charity, thereby strengthening and widening their own influence to the advantage of the community.

Prison Reform and Common Sense.

IN recent discussions regarding the treatment of the criminal a great deal has been heard about the shortcomings of our penal methods, which, if we are to believe some critics, are the product of a quite ingenious combination of cruelty and ineptitude. Much of this criticism emanates, of course, from persons who have very little direct knowledge of the details of the system on which they so confidently pass judgment, and little, if any, real acquaintance with the factors of the problem which this system has to meet; and, indeed, the very exaggeration of their censure is sufficiently suggestive of this fact to breed suspicion in the judicial mind. That type of mind, however, is hardly so general that it is safe to trust entirely to its discriminating action in matters of this sort; and it is therefore desirable that such inaccuracies should not be merely ignored as patently false, but that they should be authoritatively contradicted. This necessary task has been admirably carried out in a very interesting volume of reminiscences which Dr. R. F. QUINTON, lately governor of H.M. Prison, Holloway, has recently published under the title of "Crime and Criminals, 1876–1910."[1]

Dr. QUINTON was a medical officer in the prison service for many years before he was called on to take up disciplinary duties as a governor, and he had thus exceptional opportunities for observing the working of the prison system from two different, and in some respects almost opposed, points of view. Moreover, the years of his service fell in a period remarkable for very far-reaching changes in ideas and in practice regarding penal methods. His account, therefore, of the evolution of our prison system is based on an unusually wide and varied experience, and it is evident from a perusal of his book that he has made the most of his opportunities, and that throughout his career he has been able to apply to the facts coming under his observation an acute and critical judgment and a flexibility of ideas which popular prejudice does not usually associate with the official mind. It is gratifying to find that an observer so well qualified to judge does not share the unfavourable opinions which so many critics have recently expressed regarding the value of the penal system in the repression of crime. He is prepared, on the contrary, to maintain that in the last three decades there has been a marked diminution in the amount of serious delinquency, and in confirmation of his view he is able to point to the steady decrease of the daily average population of our prisons, and more particularly of our convict prisons. Still more striking is the testimony which he bears to the change that has come over the type of criminal. Such appalling deeds as the Houndsditch murders, though they are frequent in the records of crime on the Continent, are providentially rare with us, and when they occur in this country the criminals are invariably aliens. Our social improvement is apparent, not only in the greater rarity of ferocious crimes, but also in the very much better standard of conduct in prisons. While recognising, of course, that this change is largely due to general civilising influences, amongst which the spread of popular education is the most

[1] London: Longmans, Green, and Co. 1910.

important, Dr. QUINTON claims that some part of the credit is also due to the more humane spirit in prison administration, to the better treatment of the prisoner in the matter of diet and employment, and to the restriction of corporal punishments to offences of gross and brutal violence. At the same time it has to be remembered that the average prisoner, though very much better than he used to be, has not yet reached the altitude of moral and intellectual superiority where the fancy of the sentimentalist sometimes places him.

The failure to recognise this fact may easily lead to such results as Dr. QUINTON humorously typifies in the story of the female prisoner provided with a volume of some literary quality and using the pages to curl her hair. The fallacy of the amateur prison reformer, as Dr. QUINTON rightly insists, lies in this substitution of a figment of the imagination for the flesh and blood reality which penal systems have to deal with, and this fallacy not only makes the captious critic discover imaginary faults but it also blinds him to what is the real defect of that system—namely, its entire unsuitability to large classes of persons who have been forcibly and very unwisely brought under its influence. So long as wandering lunatics, mental defectives of all sorts, vagrants, and inebriates are poured into prisons, it is idle to suppose that these institutions can be made to exercise their full reformatory influence on normal offenders. This obvious truth has been insisted on by prison officials in season and out of season; its force is admitted by every section of enlightened public opinion, but nothing is done to remedy the evil. Dr. QUINTON is fully justified in maintaining that the prison administration which in the face of such difficulties has devised and brought into operation such measures as the Borstal treatment of adolescent offenders, and which has raised the hygienic standard of our prisons to its present level, has proved its efficiency. This interesting sketch of our prison system may be commended to the attention of all who are interested in the problems of criminality, and their appreciation of it will doubtless be in no way lessened by the fact that the author's keen sense of humour has enabled him to see, and to make his readers see, the comic side of many of his official experiences.

Annotations.

"Ne quid nimis."

SIMPLE DIETETICS AT CHRISTMAS.

PHYSIOLOGY has long taught the advantages of simplicity in dietetic matters, and its warnings may well be borne in mind in the approaching festive season. All that counts for enjoyment is not condemned by physiology, for, as is well known, the appreciation of food contributes largely to its due appropriation for the bodily needs. A joyous environment is equally valuable and a festive occasion is not necessarily a physiological immorality. The Christmas dinner, which is a highly cherished institution, is, after all, a simple affair, and its ingredients are in general of the most wholesome kind. Why do humorists persistently represent the opposite view? Roast beef or turkey and plum pudding represent in plain terms the constituents of what is from a physiological point of view a complete diet, presenting all classes of reparative material demanded by the great processes of nutrition. It contains a balance of proteins, fats, carbohydrates, and mineral salts which go to make up healthy tissue. The plum pudding in particular is a complete food in itself, and the only risk of the Christmas meal is taking an excess of the good things which it provides. Fortunately, people nowadays do not need to be told to guard against excess. Life has become a strenuous affair, and all know that to trifle with the nutritive processes is to be left behind in the race. Politicians are prone to allude to the altered habits of the people, and what they really mean is that greater care is now exercised as to the quality and quantity of the food and drink consumed, while the people have found out that a festive occasion is not robbed of its joyousness because a temperate path is chosen. The gospel of temperance in regard to both eating and drinking has been preached most effectively by the medical profession, and laymen are numerous enough who possess a sensible acquaintance with simple physiological facts to guide them. This knowledge, however, is not a fetter to their liberties, nor does it diminish the joy of a festive season. Swinish bouts are, practically speaking, a thing of the past, and everyone rejoices that that is so. There is not a single item in Christmas cheer which need be taboo to the most rigid of physiologists when there is no abuse of the good things of the feast. There may be indeed some increased demand upon the digestive organs, but it is a demonstrated physiological fact that the cheerfulness of the occasion lightens this burden. Indigestible dishes are not, as a rule, the feature of the Christmas dinner table; it is difficult to select anything more digestible than turkey, roast beef, or Christmas pudding eaten in balanced quantities. There are plenty of other meats and sweets which are far more trying to the digestive apparatus than these. The simplicity of the English Christmas table is much in its favour, and no sensible person spoils the merit of this simplicity by indulgence. During the Christmas festivity, having regard even to the finest requirements of the functions, it is possible to be merry and wise together, a line of conduct which is in complete allegiance to physiological orders.

THE USE OF THE "SOY BEAN" AS A FOOD IN DIABETES.

THE "soy bean" (glycine hispida) has been extensively cultivated for human consumption in China, Japan, and Korea since before the time of Confucius, but in Europe and America it has been grown only to a comparatively limited extent, chiefly as a forage crop, and that within the last 15 years. It is an annual of the natural order leguminosæ. The beans are eaten as a vegetable, in soups, sometimes pickled green, boiled and served cold with a sprinkling of soy sauce, and sometimes as a salad. It forms the basis of the soy sauces which are so extensively used in the preparation of condiments; and a favourite method of preparing it in the Far East is by boiling the beans until soft, and placing the resulting mass in a warm cellar until it ferments, the result being a form of bean cheese known as "natto." An analysis of the yellow beans grown in America shows, when calculated to a water-free basis: protein, 38·50 per cent. and fat, 20·00 per cent.; and it is probable that this large percentage of easily convertible nitrogenous material accounts for the small amount of meat and other animal foods consumed by the rice-eating Chinese and Japanese. Its medical interest, however, depends largely on the fact that, unlike most pod-bearing leguminosæ, which are extremely rich in starchy material, the soy bean is almost starch free, a phenomenon which is said to be due to the presence of a diastase in the

bean capable of converting any starch formed, two-thirds into sugar, one-third into dextrin. This absence of starch suggested to observers some years ago that the bean might be advantageously used to vary the somewhat restricted diet of the diabetic, and in the *American Journal of the Medical Sciences* for December Dr. Friedenwald and Dr. Ruhräh record the results in eight cases of the disease treated by them. In each case the total quantity of urine, the percentage of sugar, and the quantity of sugar in grammes excreted in 24 hours were noted under the following conditions. First, the patient's excretions were examined on an unrestricted diet; next, under the ordinary restrictions of diabetic cookery; and, finally, on a diet of the usual diabetic foods, *plus* soy beans, the beans replacing largely the gluten of wheat bread. In each case there was a marked diminution in the total quantity of sugar excreted in a test 24 hours. Case 1 on unrestricted diet excreted 45 grammes per diem, on diabetic food 30 grammes, and on a mixture of diabetic food and soy beans 20 grammes. In Case 2 the fall was from 90 to 48 to 31 grammes; Case 3 fell from 92 to 58 to 40 grammes; Case 4 from 94 to 50 to 43; Case 5 from 58 to 0 to 0; Case 6 from 132 to 75 to 54; Case 7 from 122 to 93 to 63; and Case 8 from 143 to 79 to 40. It will thus be seen that except in Case 5, where ordinary diabetic food completely controlled the sugar excretion, there was a marked improvement on the ordinary treatment when soy beans were added to the dietary, and the conclusions arrived at by the investigators, therefore, are that the soy bean is a valuable addition to the dietary of diabetics on account of its palatability and the numerous ways in which it can be prepared, and that in some manner or other the bean causes a reduction in the percentage and total quantity of sugar passed by diabetics under the usual dietary restrictions.

MYCOSIS FUNGOIDES WITH DEPOSITS IN INTERNAL ORGANS.

AN interesting case of mycosis fungoides with rare, if not unique, features was described by Professor Paltauf of Vienna before the Section of Pathology of the Eighty-second Congress of German Naturalists and Physicians held at Königsberg in September.[1] The patient was a man, aged 64 years, who had suffered from mycosis fungoides of the skin for many years. At the necropsy changes typical of this condition were found in the skin of the trunk and limbs, some areas being atrophic, others more recently affected presenting ulcerations and crusts. On the mediastinal pleura of the right side there was a flat disc-shaped thickening 2½ centimetres in diameter, which was opposed to a similar patch on the mesial surface of the upper lobe of the lung. A smaller patch, circular in outline and sharply defined, was situated near to this, while a third was placed a few centimetres away and more dorsal in position. All three patches were flat and resembled those in the skin, especially in being redder at the periphery and paler or more yellow centrally. Numerous nodules were present in the lungs, some forming circular raised patches on the pleura, others forming tumours within the lung tissue varying in size from a cherry to a hen's egg. Some of these were degenerated centrally and presented a gelatinous appearance; others were dry and necrotic. Occasionally a central cavity with smooth walls was present. The branches of the bronchi and pulmonary artery passing to the larger nodules could usually be seen, and they were often obstructed or blocked. The peripheral parts of the nodules were markedly reddened and sharply demarcated by a firm zone of infiltration. Deposits were also found in the stomach, the mucous membrane of the fundus presenting small round ulcers with raised, infiltrated edges. Certain lymphatic glands also presented changes. The bronchial glands on the right side were enlarged, and those of the right axilla were adherent to the connective tissue, and on section showed central softening or necrosis, while the glands in the groins were firm, adherent to the connective tissue, and on section were found to be pigmented. Histological examination of the nodules in the pleura showed a granulation tissue composed of various cells similar to the typical appearances of mycosis fungoides in the skin nodules. The tumours in the lungs possessed a wide zone at the periphery, in which the alveoli were filled with fibrinous exudate, while the alveolar walls showed a cellular infiltration. Internal to this zone there was a central area made up of a granulation tissue composed of various kinds of cells, with a delicate reticulum like that of the cutaneous growths. Nuclear degeneration and the crumbling of the protoplasm described by Unna as occurring in the skin nodules were also present. A similar granulation tissue rich in cells was found in the gastric mucous membrane, while the bases of the ulcers were formed of ordinary granulation tissue. The bone-marrow and the lymph glands also presented microscopical appearances which agreed with those of mycosis fungoides. Various methods, including that of Levaditi, were employed to discover the exciting cause of the disease, but all yielded negative results. Professor Paltauf drew attention to the rarity of his case, and claimed that it was unique, since in the few recorded cases of internal tumours occurring in mycosis fungoides these have proved to be of lympho-sarcomatous nature, secondary to similar lesions in the skin.

AN ANECDOTE OF DR. CAIUS.

IN Mr. Noel Barwell's instructive and amusing account of the history of the University of Cambridge, which, with admirable colour-illustrations, has just been published by Messrs. Blackie and Son in the "Beautiful England" series, there naturally occurs some account of the famous Dr. Keys, or Caius, founder of Gonville and Caius College. This great President of the Royal College of Physicians of London, who lies buried in his "beloved College in Cambridge," shortly before his death, when the massacre of St. Bartholomew still horrified the popular imagination, was the victim of persecution at the hands of Commissioners, who burnt his collection of Catholic vestments and other religious paraphernalia within the precincts of his own college. It was the attachment of Caius to the old religion that may account for a curious and undignified story that is related of his last hours, and is probably traceable to a Puritan gossip-monger. "In his last illness," says Mr. Barwell, "he endeavoured to sustain life by a return to the natural nourishment of infancy; and divers dames of the town were privileged to minister to his wants in this respect. Being observed to be now 'froward, peevish, and full of frets,' and now tractable, docile, and of an amiable countenance, his moods and tempers were considered to vary with the individual source of his curious refreshment." The authority for this strange story, which is a kind of reminiscent travesty of the legend of Ugolino, who was suckled in prison by his daughter, is not vouchsafed us, but it is doubtless well known. An account of the life of Caius, published in 1857 by Tegg, quoted a curious passage in Dr. Moufet's "Health's Improvement." Dr. Moufet, or Moffett, physician and naturalist, who died in the year 1604 (31 years after Caius), was partly educated at Cambridge, and studied medicine under Caius. The passage is as follows: "What made Dr. Caius in his last sickness so peevish and so full of frets at Cambridge, when he sucked one woman (whom I spare to name), froward of conditions and of bad diet; and contrariwise, so quiet and well, when

he sucked another of contrary dispositions? Verily, the diversity of their milks and conditions, which, being contrary one to the other, wrought also in him that sucked them contrary effects." Curious death-bed expedients were sometimes resorted to in ancient times. We need only cite the case of King David and the Shunammite who "cherished" him in his extreme old age. The suckling story was probably indigenous in ancient Cambridge; based on fact, it may have been applied to successive unpopular characters. Caius died in distress at the persecutions to which he had been subjected, and at the gross ingratitude of the members of the society which he had founded. Religious hatred accounts for several famous death-bed traditions. Thus Voltaire is said to have died in panic-terror, but the story is very probably a clerical invention due to Voltaire's life-long scoffs at orthodoxy. France has, indeed, been the cradle of numerous discreditable stories of this kind concerning eminent free-thinkers—men of science or realistic writers—who, being dead, cannot exonerate themselves.

THE TREATMENT OF "CENTRAL OSTEITIS" WITH METAL TUBES.

THERE is a tendency in surgery, which is inherent in human nature, to strive after brilliant and spectacular effects, and any disease, chronic in its nature, and not directly fatal to the patient, which refuses to yield to rapid measures, or to give easily appreciable results, is liable to recede into the limbo of forgetfulness, and be relegated in hospitals to the house surgeon or dressers, or, owing to the pressure on beds by more acute and more rapidly healing cases, transferred eventually to the chronic wards of the great Poor-law infirmaries. Even amongst the well-to-do the same result holds good, for without the stimulus of active inquiring minds treatment does not advance, and if a subject is unattractive newer and more scientific methods of procedure are not evolved. No better example could be chosen than that of "central osteitis," for up to recent times no real advance has been made since Sir Benjamin Brodie in 1832 advocated trephining in chronic abscess of bone. The difficulty of these cases, as in the analogous ones of sinuses leading down to bone, is that they all show thickening of bone from infective osteitis and periostitis, and the walls of the cavities inside are composed of dense sclerosed bone which cannot collapse when pus is evacuated, and that there are often many small chambers and tracts of septic material in the bone which it is impossible to follow, as the dentist does in the analogous case of a carious tooth. The difficulty in diagnosis, too, in neglected cases has in the past been great, for a swelling at the end of a long bone might be simple, tuberculous, syphilitic, or possibly malignant, and the presence of a sinus did not exclude a mixed, simple, and tuberculous infection, or syphilo-sepsis. These difficulties have in recent years, however, been greatly simplified, radiography, Wassermann's reaction, and the systematic bacteriological examination of discharges having cleared the ground considerably. More particularly in the bacteriology of these conditions have advances been made, and it is now known that chronic comparatively painless abscesses may be caused by staphylococci, streptococci, pneumococci, and the typhoid bacillus, morbid conditions which serum and vaccine therapy have been able considerably to ameliorate. Nevertheless, a large field still remains for the surgeon, and Mr. Charters J. Symonds is to be congratulated on taking up the subject in his address before the Medical Society of London, and introducing to its notice a new method which has the advantages of being simple as well as efficacious, allowing also the patient to walk about, a most important desideratum, especially in hospital cases. The method described is, after opening up the medulla with a gouge or trephine, to insert a metal tube of half-inch diameter, composed of silver, German silver, or aluminium, fitted with a flange externally, and, for convenience of reintroduction, supplied with a conical pilot of boxwood or German silver. The metal tube gives rise to no irritation, can be readily taken out, boiled, and reintroduced by the patient, and does not hinder him working. At the end of six or 12 months the tube can be reduced in size, and finally a solid metal rod, with a flat nail head, or a piece of thick silver wire with a bent-over end externally, can be left in. These solid drains, Mr. Symonds finds, answer very well and might perhaps be used after six months. Practically all that seems necessary is a vent for a small amount of secretion, and this can escape by the side of the rod. As an example one case may be quoted, that of a woman aged 42 years. At the age of 11 she had acute necrosis of the tibia on the left side and smaller foci at the lower end of the right femur and both humeri. At 39 years of age a small sequestrum separated from the right femur. When seen at the age of 42 she had a painful swelling at the lower end of the right tibia, present for three months, but with the limb occasionally painful for the previous ten years. The bone was trephined and thick creamy pus came from the central cavity. It was drained by a half-inch metal tube, and the patient was soon allowed to walk about. The tube gave no trouble, she took it out, and boiled it herself daily. A smaller tube was introduced at the end of 12 months, and meanwhile the swollen tibia slowly reduced in size. At the present time, nearly two years after, the bone appears to be normal. At the discussion that followed all the surgeons present condemned the usual treatment with rubber tubes and gauze packing. Injections of plaster-of-Paris were also said to be useless, though several surgeons indicated that they had had successes with soft bismuth paste, as advocated by Dr. Beck of Chicago. Injections of iodoform and spermaceti wax after a preliminary curettage were also advocated in certain cases, especially tuberculous, and when the bone would not be too much weakened by the treatment, removal of all the diseased tissue, allowing the soft parts to fall in over the deficiency, had its advocates. Nevertheless, that a new weapon in treatment had been presented seemed to be the general consensus of opinion at the meeting.

FATAL HEMIPLEGIA IN SECONDARY SYPHILIS FAILURE OF DIOXYDIAMIDOARSENOBENZOL.

THE acceptation of the treatment of syphilis by dioxydiamidoarsenobenzol has been very general, and that in many hands it has been found a remarkable remedy for causing the disappearance of the symptoms of syphilis, sometimes after the failure of ordinary treatment, cannot be gainsaid. Evidence of limitation of its powers is at present meagre, but it is to be hoped that failures with the remedy will be fully reported, so that the medical world may be fairly guided in its attitude. The following case, which was reported at a meeting of the Société Médicale des Hôpitaux of Paris on Nov. 4th by M. Georges Guillain and M. P. Ravaut, is an example of such failure, and is of interest on other grounds—the rarity of hemiplegia and death in the secondary period of syphilis. A woman, aged 28 years, was admitted into the Cochin Hospital on August 14th, 1910, suffering from left hemiplegia, which began on the previous evening. Twelve months previously she was treated at the Broca Hospital for a chancre. After a month she abandoned treatment against advice. On admission she was in a state of obnubilation with dysarthria. There was flaccid hemiplegia of the left limbs, but the face was involved only slightly. On the paralysed side the knee-jerk was feeble,

the abdominal reflex was abolished, Babinski's sign was present, and forced flexion of the toes caused reflex retraction of the lower limb (a phenomenon recently described by Marie and Foix in lesions of the pyramidal tract). There was incontinence of urine and fæces. The pupils reacted to light. Around the anus were condylomata. Lumbar puncture yielded clear fluid containing numerous lymphocytes and polynuclears, but with the ultra-microscope no spirochætæ could be seen. On the 15th, 16th, 17th, and 18th an injection of 2 centigrammes of biniodide of mercury was given. Slight improvement in the mental condition and in the paralysis took place. On the 19th some dioxydiamidoarsenobenzol was received from Professor Ehrlich and 0·45 gramme was injected. No toxic symptoms followed the injection and the condylomata diminished, but the mental condition and the hemiplegia appeared to be worse. On the days following the injection arsenic was found in the urine. Death took place on the 26th. The necropsy showed the absence of any cerebral hæmorrhage. There was a small focus of softening in the posterior segment of the right internal capsule, slightly involving the lenticular nucleus and optic thalamus. To the naked eye all the viscera were normal, but microscopic examination of the liver showed slight fatty degeneration. It is noteworthy that the patient was improving under the mercurial treatment before the injection of the dioxydiamidoarsenobenzol, and that the cause of the hemiplegia was not a gross incurable hæmorrhage but a small focus of softening. M. Guillain and M. Ravaut do not suggest that death occurred in consequence of the injection but in spite of it.

THE USE OF THE REVOLVER.

WE desire to express our deep sympathy with the relatives of the three policemen murdered by revolver shots recently in Houndsditch, with their wounded companions, and with the relatives of the latter. We need not recapitulate the facts attending a tragedy to which full publicity has been accorded in the public press, and which is fresh in the memory of all, in order to point out, as we desire to do once more, the extraordinary indifference of the legislature to the habitual carrying of firearms in this country by criminals and others. In the recent affray the only persons who were not at liberty to carry firearms, if they chose to do so, were the police, and it may be that what then happened will lead to the police force being better armed in future, at any rate, when their duties have to be carried out in dangerous localities, or in their being permitted to use firearms when such are employed against them. The general freedom of anyone who chooses to do so to carry a pistol in Great Britain has been a subject of frequent comment in THE LANCET, and we have called attention constantly to accidents, as well as crimes, due to what is apparently a common practice with certain classes of society. A futile Act of Parliament imposes upon the sale of these weapons certain restrictions which include the production of a ten-shilling licence by the purchaser. Anyone who has such a licence is entitled to walk about with a deadly weapon in his pocket, or, as far as we are aware, in his hand, as long as he does not otherwise transgress the law, and even if he has no licence at all he is only committing an offence affecting the national exchequer, for which the Inland Revenue authorities, if they detect him, are able to prosecute him and have him fined. In our opinion, the carrying of a revolver in any public place should render any person found guilty of doing so liable to severe penalties, not excluding imprisonment, with such exemption as may be required to meet the exigencies of military training. For the defence of a man's house he must be permitted to own a revolver, if he should desire to do so, but it might be advantageous to the community if, even as a preliminary to this, the householder were to be obliged to comply with suitable but not onerous conditions. A tax, heavy in proportion to the cost of the cheaper class of weapon, should keep out of the country a large number of revolvers now brought in from abroad, and should make the question of purchase a serious one for schoolboys and for the needier class of lunatics, irresponsible persons, and criminals. Here again exemptions affecting weapons to be used for military and naval purposes or in dangerous foreign countries could be framed without difficulty. The searching of persons suspected of infringing the law, or of introducing revolvers into the country without paying duty at the port, are matters which would follow as a matter of course. We do not claim that legislation upon the lines which we suggest would render such crimes as that which recently took place in Houndsditch impossible, but desire rather to protest against an easy-going indifference which renders them easy. The question of arming the police is one of some difficulty, and is not one upon which we feel called to express an opinion, except to point out, as we have done, the freedom permitted to the criminal to arm himself as he pleases.

THE TREATMENT OF DYSPHAGIA IN LARYNGEAL TUBERCULOSIS.

THE pain on swallowing which occurs in laryngeal tuberculosis constitutes one of the most distressing features of this condition, and often leads to severe emaciation from the deficient amount of food which the patients are able to swallow. In 1908 Dr. Hoffmann[1] of Munich recommended the injection of alcohol into the internal branch of the superior laryngeal nerve and described good results from this procedure. In 1909 Dr. Sturmann reported a case with severe dysphagia which was relieved by this method. Dr. J. Dundas Grant has recently recorded in THE LANCET[2] six cases which were selected for this treatment on account of the extreme severity of the pain. They seemed to him to justify its recommendation. An interesting paper was published by Dr. Gottfried Roth of Bad Reichenhall in the *Münchener Medizinische Wochenschrift* of Oct. 18th, recording his experience of this method of treatment, which he has employed in 33 cases. Of these, 23 were men and 10 were women, and all excepting three suffered also from advanced pulmonary tuberculosis as well as laryngeal. In half of the cases there was perichondritis of the epiglottis with ulceration, in the other half there were infiltrations and ulceration of the vocal cords. In 15 perichondritis and ulceration of the arytenoid cartilages were also present, and in 6 infiltration and ulceration of the posterior wall of the larynx. Dr. Roth found that alcohol injections were useful in cases where there was dysphagia, provided this was not due to changes in the pharyngeal mucous membranes or in the tonsils. In all of his cases the ordinary local anæsthetics had proved ineffective. Most of the patients found more pain and difficulty in swallowing liquids than solid or semi-solid food, and in some the swallowing of saliva caused great pain and discomfort. Most of them found it easier to swallow warm or lukewarm food, cold things tending to excite painful cough. Neither fever nor advanced cachexia contra-indicated the use of alcohol injections. The method of giving them is by means of Schlösser's alcohol syringe fitted with a special needle devised by Dr. Hoffmann. The patient should be recumbent with a pillow under the neck in order to stretch the soft tissues. A characteristic spot, tender to pressure, is easy to find between the hyoid bone and the thyroid cartilage, corresponding to the spot where the

[1] Münchener Medizinische Wochenschrift, No. 14, 1908.
[2] THE LANCET, June 25th, 1910, p. 1754.

internal branch of the superior laryngeal nerve pierces the thyro-hyoid membrane. This spot is usually present on the side corresponding to the laryngeal lesion, though in cases where the epiglottis or both arytenoids are affected tender spots are present on both sides. The skin over the tender area should be cleaned by means of alcohol and ether, and the larynx steadied by means of the thumb. The index finger applied to the tender spot serves as a guide, and the needle of the syringe is inserted for 1½ centimetres. It is then turned upwards and outwards. If the patient complains of severe pain radiating towards the ear, this may be taken as proof that the nerve has been reached. A small quantity of 85 per cent. alcohol heated to 45° C. is then cautiously injected, the amount being usually 1 gramme, though sometimes 1½ or even 2 grammes have been used. In most cases only one side was injected, but in two an injection was given on the opposite side immediately after the first. No serious unpleasant symptoms occurred after the injections. One patient developed a severe attack of coughing during the injection, so that the needle went into the subcutaneous tissue. This was followed by cutaneous emphysema, which disappeared after two days. One patient with advanced cachexia fainted after the injection. Sometimes pain in the ear and headache followed. The dysphagia was greatly relieved in all of the cases except one. The improvement occurred almost directly in a few of the cases, but in most it developed within one or two days after the injection, and lasted, on an average, seven days. In one case the improvement was permanent. Apart from this, the longest period of relief was 21 days. The shortest was one day. The injection appeared to have no effect whatever, either beneficial or otherwise, on the cough, but in some cases the hoarseness appeared to be less. Since the good effects only last, as a rule, about seven days, the injections have to be repeated, and in one of Dr. Roth's cases this was done five times. It is not suggested that this procedure has any curative value, or that it should be employed where local anæsthetics are effective. Dr. Roth is careful to suggest its use only in cases of advanced laryngeal disease where swallowing is difficult or almost impossible, and where local anæsthetics have failed. The condition of these patients is so grave and their sufferings are so severe that any procedure affording even temporary relief is welcome, if it can be shown that its employment does not cause unpleasant symptoms or after-effects.

CUTANEOUS DIPHTHERIA.

THE subject of cutaneous diphtheria does not appear to have received much attention in this country. A short time ago Dr. Alan B. Slater reported in our columns[1] a remarkable case of three years' duration. The patient was a girl, aged 13 years, whose body was covered with vesicles containing the diphtheria bacillus. The disease appeared to have begun as an acute attack of diphtheria of the conjunctivæ. The vesicles developed on the vulva, and subsequently on the body generally. In the *Boston Medical and Surgical Journal* of Nov. 10th Dr. E. H. Place has reported a case of fatal primary diphtheria of the skin. An infant, aged 7 months, was admitted into the Boston City Hospital on March 24th, 1908. She was breast-fed, and had always been well except for eczema of the pubic region, groins, and thighs, which dated from birth. Two days before admission swelling and redness became marked over the area of the abdomen, genitals, and thighs which was covered by the diaper. There was a considerable thin discharge. On examination the child was well developed and fairly well nourished. The nose, mouth, and throat were normal and there was no nasal discharge. The temperature was subnormal. The pulse was 140 and the first cardiac sound was softened. A few crackling râles were heard over the bases of the lungs. The skin of the lower third of the abdomen, vulva, perineum, anterior part of the buttocks, and upper part of the internal surfaces of the thighs was red, swollen, and covered with a greyish hyaline membrane which was firmly adherent and when forcibly removed left a granular area which bled easily. Scattered over this area were small variously shaped islands of normal skin. There were no vesicles or pustules. The treatment consisted in the administration of strychnine and 1200 units of antitoxin and the application of boric acid dressings. On the third day after admission the membrane was clearing rapidly, but there was no improvement in the general condition, and the heart's action was rapid and very weak. The child's colour became a peculiar grey and the first cardiac sound was almost imperceptible. Numerous crepitant râles were heard at the bases of the lungs and death occurred. Cultures from the skin showed typical diphtheria bacilli which were identified both by cultural tests and inoculation of animals. Cultures from the nose and throat were negative. The necropsy showed some hyperplasia of lymphoid tissue, "septic spleen," incipient bronchopneumonia, and pus in the middle ear. The source of infection could not be discovered. Evidently the disease was inoculated into the eczematous lesions by some attendant in washing the baby or changing her diapers. The onset of the diphtheria was masked by the previous eczema, and not until the disease was widespread was medical advice sought. Hence the severity of systemic symptoms. Dr. Place finds that diphtheria of the skin associated with diphtheria of the respiratory tract is not rare at the Boston City Hospital. It has been seen in the following forms during the last three years. 1. On the face and hands, appearing like impetigo contagiosa, less often with distinct membrane. Cultures show virulent diphtheria bacilli and both types clear rapidly under antitoxin. 2. On the auricle, chiefly the concha, extending from the middle ear; or behind the auricle inoculated upon the eczema so common in children. 3. Inoculated upon lupus vulgaris of the face after curetting. 4. In wounds and abscesses of the neck and face. 5. Inoculated upon varicella lesions, most commonly on the vulva or vagina.

[1] THE LANCET, Jan. 4th, 1908, p. 15.

WE regret to announce the death at the advanced age of 92 of Dr. James Edward Pollock, consulting physician to the Brompton Hospital for Consumption.

THE library and offices of the Royal Society of Medicine, 15, Cavendish-square, W. (temporary address), will be closed from Saturday, Dec. 24th, to Wednesday, Dec. 28th, both days inclusive.

THE BREAD AND FOOD REFORM LEAGUE.—Miss Yates, the honorary secretary, has received a letter from Lord Knollys conveying His Majesty's gracious approval of the work described in the report.

UNIVERSITY OF SHEFFIELD.—Mr. R. J. Pye-Smith having resigned the professorship of surgery, a resolution has been adopted accepting the resignation with great regret, and adding: "Mr. Pye-Smith, who is the senior member of the teaching staff, has been a teacher of surgery for 34 years, first in the old Medical School, next in the University College, and finally in the University, and the council desire to place on record their appreciation of the distinguished services which he has rendered to the cause of medical education in Sheffield."—Dr. E. W. Adams has been appointed lecturer in materia medica and assistant to the professor of materia medica, pharmacology, and therapeutics.

THE PRACTICAL STERILISATION OF POTABLE WATERS BY MEANS OF THE ULTRA-VIOLET RAYS OF LIGHT.

BY JOHN C. THRESH, M.D., D.SC. LOND.,
LECTURER ON PUBLIC HEALTH, LONDON HOSPITAL MEDICAL COLLEGE, E.;
AND
JOHN F. BEALE, M.R.C.S. ENG., D.P.H. OXON.,
DEMONSTRATOR OF PUBLIC HEALTH, LONDON HOSPITAL MEDICAL COLLEGE, E.

THE view generally held that water requires purification chiefly, if not exclusively, in order to prevent outbreaks of typhoid fever is probably erroneous. It has frequently been remarked that when a pure water-supply has replaced a polluted supply the prevalence of typhoid fever has decreased even when epidemics had not followed the use of the impure water. The town of Newark is a case in point. Prior to June, 1893, the supply was from the River Ouse, and the town was rarely free from typhoid fever. In the year mentioned water from the New Red Sandstone replaced the river water and immediately the prevalence of fever decreased. The following table shows the immediate and remarkable effect of the introduction of the pure water-supply:—

Cases of Typhoid Fever Notified each Six Months in the Borough of Newark-on-Trent for 3½ Years Preceding and 3½ Years Following the Introduction of a Pure Water-supply. The New Supply was laid on July, 1893.[1]

	January to June.	July to December.	Total.
1890	14	39	53
1891	60	65	125
1892	11	58	69
1893	50	28	78
1894	1	9	10
1895	2	6	8
1896	3	4	7

Total for 3½ years preceding introduction of pure water, 297.
Total for 3½ years following introduction of pure water, 53.

Recent observations, however, tend to demonstrate that a pure water-supply has a marked effect in reducing the mortality from other diseases, and Dr. Sedgwick and Dr. MacNutt of Boston have recently shown that this, which they call the Mills-Reincke phenomenon, has a basis on fact and is explained by Hazen's theorem that the substitution of a pure for an impure water-supply is followed almost invariably by a decrease in the general death-rate and by a special decrease in the death-rates from enteric fever, diarrhœa, phthisis, pneumonia, &c., and in infantile mortality also. The following table will serve as an illustration, as it enables us to compare the death-rates for two towns which are almost identical in character and in close proximity to each other, in one of which a pure water-supply was introduced, whilst the other continued to use its more or less impure supply:—

Death Rates per 100,000.[2]

—	1894–98 before filtration at Albany.	1900–04 after filtration at Albany.	Decrease.	Per cent. reduction of death-rates.
Albany.				
Typhoid fever	104	26	78	75
Diarrhœal diseases	125	53	72	57
Children under 5 years	606	309	297	49
Total deaths	2264	1868	378	17
Troy.				
Typhoid fever	57	57	0	0
Diarrhœal diseases	116	102	14	12
Children under 5 years	531	435	96	18
Total deaths	2157	2028	129	6

Remarks.—Filtered water was introduced into Albany in 1899. The water-supply of Troy has remained practically unchanged.

[1] Thresh: Water and Water-supplies, third edition, p. 162.
[2] Whipple: The Value of Pure Water, p. 10.

A study of the statistics for the borough of Newark-on-Trent, so far as they can be obtained from the Registrar-General's annual reports, shows the same marked decrease in the general death-rate after the introduction of the purer water-supply. The following figures are taken from the Registrar-General's returns, and when the corrections for variations in populations are made it is found that the average death-rate for the town during the five years preceding the one in which the pure sandstone water was introduced averaged 18·4, whilst in the five years following it was only 15·6, a result much like that observed at Albany, U.S.A. Only about 3 per cent. of this decrease could be attributed to enteric fever.

Year.	Population.	Total deaths registered.	Year.	Population.	Total deaths registered.
1888	14,083*	248	1894	14,571†	240

* 1881 census. † 1891 census. ‡ 1901 census.

Assuming the correctness of this theorem the question of purification of public water-supplies becomes of enormously increased importance, since such purification will not merely prevent a few cases of enteric fever annually but it will effect a large annual saving of lives which otherwise would have been sacrificed, and especially of lives of young children.

During recent years many attempts have been made to improve upon the old, and where properly conducted excellent, system of purification by means of slow sand filtration. Most of these systems have been failures, but three remain which may play an important part in the purification of water in the future. These are sterilisation by means of (*a*) ozone, (*b*) chlorine, and (*c*) ultra-violet rays of light. The first, the ozone process, labours under the disadvantage of requiring an exceedingly complex electrical installation which requires specially skilled supervision. The second, or chlorine process, suffers temporarily from sentimental objections. When these are overcome, as doubtless they will be since such treated waters are now being used for public supplies, the process will probably be largely adopted, especially when a cheap supply of electricity is not available. The third is not subject to any of these disadvantages. Where electricity is available an installation of a very simple character requiring very little supervision can be laid down, and if the results already obtained can be maintained for long periods the process should have a great future before it, since it can be used for purifying the supply of a single house as well as for the purification of the supply to the largest city.

It has long been known that the invisible or ultra-violet rays of the solar spectrum are capable of producing marked chemical changes, and recent experiments have shown that rays of a certain wave length are much more powerful than those of shorter or longer length. The rays emitted by the Cooper Hewitt mercury vapour lamp are found to be particularly rich in these active rays, and in 1906 Nogier and Therenot demonstrated that the rays of this lamp exerted a marked bactericidal action. Nogier conceived the idea that the lamp might be ultilised for the sterilisation of water, and his further researches demonstrated that his idea was correct. The mercury lamp is used for the production of the rays, but it having been discovered that glass absorbed the specially active rays fused silica has been substituted for it. Nogier immerses the lamp in the water to be sterilised, but other forms of apparatus are made in which the water does not come in contact with the lamp.

A priori it would be imagined that, as the intensity of the action of the rays varies inversely as the square of the distance from the source of light, the immersed lamp should have a more powerful effect, and this is supported by the results of the experiments, which we have recently been able to conduct in the hospital laboratory. For the Nogier lamp it is also claimed: (1) that with a given amount of electrical current much more water can be sterilised than with an external lamp; (2) that the lamp being kept cool will last longer; and (3) that the apparatus can be made smaller, more compact, and automatic. The advocates of the external lamp say that the immersed lamp is more liable to fracture and that in time it will become covered

with calcareous deposit and lose its efficiency. On the other hand, it is affirmed that the difficulty which at first occurred from breakages has been surmounted, and that any calcareous deposit which may form can be easily removed with dilute acid, and it is alleged that the external lamp, on account of the heat engendered, becomes affected to such an extent that its sterilising effect is speedily decreased owing to some molecular change in the internal surface of the fused silica. Time, however, is necessary to demonstrate the truth or otherwise of these allegations.

The Nogier lamp has been severely tested in France. The small-sized machine used for this purpose, both by Miguel in Paris and by ourselves in London, consists of an aluminium cylinder about 12 inches long and 6 inches in diameter, containing a Cooper Hewitt quartz lamp with an internal diaphragm, which causes the water entering at one end to travel along the cylinder in close proximity to the lamp. After traversing the length of the lamp it passes away through an opening at the end opposite to the inlet. By a very ingenious arrangement no water can flow through the cylinder unless the lamp is glowing. The instant the current is cut off or the lamp ceases to glow the cylinder tips up and the flow of water ceases. It is practically impossible, therefore, to obtain water from the cylinder unless it has been submitted to the action of the ultra-violet rays. This small lamp is capable of purifying from 50 to 200 gallons of water per hour according to the original character of the water. Possibly more could be sterilised in some cases, but in our experiments we have been unable to obtain sufficient pressure from the London mains to force more than this quantity through it.

Miguel's experiments showed that in clear and bright water many bacteria are killed after from 5 to 20 seconds' exposure to the ultra-violet rays, and that the most resistant spore-bearing bacteria were destroyed in from 30 to 60 seconds. The bacillus coli was killed in from 15 to 20 seconds, the bacillus typhosus in from 10 to 20 seconds, the cholera vibrio in from 10 to 15 seconds, &c.

Of the remarkable bactericidal action of the ultra-violet rays there could be no doubt, but it was observed that a faint turbidity in the water or the presence of traces of colloid matter greatly retarded the action. We were anxious, therefore, to test the apparatus with polluted waters such as might be used for potable purposes if they were efficiently sterilised. A small apparatus capable of treating 200 gallons per hour was therefore installed and connected with a large tank holding sufficient water for experimental purposes. Another connexion was also made with the water main, so that the apparatus could be kept working for hours at a stretch.

The first series of experiments was directed towards ascertaining whether the treated water suffered any change which could be detected by chemical analysis. In all the experiments the apparatus worked with an electrical current of 6 ampères and 130 volts, and it was found that the amount of current used was just under one Board of Trade unit per hour. For the chemical and physical tests the water was passed through the apparatus at the rate of only 10 gallons per hour, so as to obtain a maximum effect from the ultra-violet rays. The analysis showed that the chemical constituents of the water remained unchanged. The slight differences in the results were practically within the limits of error of a careful analysis. No ozone could be detected. It is improbable, therefore, that the sterilising effect is due to ozone, as some have surmised. One effect, however, was observed which is worth recording. One of the samples of water treated had a faint but decided odour suggestive of sewage, whereas the treated water was devoid of odour. The analytical results in this case were :—

	Untreated water.	Treated water.
Free ammonia, parts per 100,000 ...	0·0474	0·0436
Albuminoid ammonia	0·0188	0·0192

The difference in all other respects was *nil*. The very slight reduction in the free ammonia does not appear to be capable of explaining the disappearance of the odour. This was an exceedingly impure water, yet it was found that the apparatus practically sterilised it.

In passing through the steriliser the temperature of the water is slightly raised. When the water was travelling at the maximum rate, 200 gallons per hour, the rise in temperature varied from 0·2° to 0·4° C. When passing at the minimum rate used in the bacteriological experiments, 30 gallons per hour, the increase in temperature was 1·8° to 2·2° C. The bacteriological results were as follows :—

Experiment 1.—Water from main run into a dirty cistern and well stirred. Samples of treated water taken at half-hour intervals. Rate of flow 30 gallons per hour throughout. Under the head of "gelatin" is recorded the number of bacteria per c.c. capable of growing on jelly in four days at 20° C., and under "agar" the number of bacteria per c.c. growing in two days at 37° C. upon an agar medium.

—	Gelatin.	Agar.	B. coli.
Untreated water	3200	1180	Present in 100 c.c.
Treated water 1	0	0	Absent in 500 c.c.
,, ,, 2	2	3	,, ,,
,, ,, 3	4	0	,, ,,

The water therefore was practically sterilised and freed from the bacillus coli.

Experiment 2.—The tank was next filled with water and 0·5 per cent. of filtered sewage added. The untreated water had a faint odour of sewage. The treated samples were free from odour. The rate of flow varied from 11 to 60 gallons per hour. The pressure available did not permit of a larger quantity being passed through the apparatus.

—	Gelatin	Strepto-cocci.	B. coli.	B. enteritides sporogenes.
Untreated water	5500	In 10 c.c.	In 0·1 c.c.	In 100 c.c.
Treated water—rate of flow :				
11 gallons per hour	18	Absent in 110.	Absent in 636.	Absent in 500.
22 ,, ,,	10	,,	,,	,,
45 ,, ,,	16	,,	,,	,,
60 ,, ,,	23	,,	,,	,,

All these treated waters are of the highest degree of bacterial purity, though not sterile.

Experiment 3.—This experiment, or rather series of experiments, was spread over a period of several days. The apparatus was directly connected with the main in order to obtain sufficient pressure to work the apparatus at its maximum capacity. From time to time a sample of the water passing into the steriliser was collected for examination.

—	Gelatin	Agar.	B. coli.	Rate of flow per hour.
Untreated water ...	140	80	In 100 c.c.	—
Average treated water	5	1	Absent in 500.	80 gallons.
Untreated water ...	62	34	In 20 c.c.	—
Treated water	2	0	Absent in 500.	80 gallons.
,, ,,	4	2	,, ,,	100 ,,
,, ,,	3·5	1·5	,, ,,	120 ,,
Untreated water... ...	110	48	In 100 c.c.	—
Treated water	6	3	Absent in 500.	140 gallons.
,, ,,	6	3	,, ,,	160 ,,
,, ,,	6	3	,, ,,	200 ,,

The last average (200 gallons per hour) does not include one abnormal result, the treated water giving 50 bacteria on gelatin and 18 in agar per c.c. Even with this exceptional number of bacteria the bacillus coli was absent in 500 c.c. of the treated water.

The whole of the results show that with a fairly clear and bright water the ultra-violet rays as applied in the apparatus employed produced a sterilising effect sufficiently marked to convert a dangerously polluted water into a safe potable water.

The extreme simplicity of the apparatus and its comparative cheapness both as to first cost and working, render it particularly suitable for purifying clear waters such as

are usually derived from wells, especially when electrical current is available. When turbid waters have to be treated, such as supplies from streams and river, prior filtration will be absolutely necessary to render the water bright. The apparatus could in such cases be connected with the outlet from a mechanical filter.

The experimental results thus far obtained are so encouraging that experiments on a very much larger scale are about to be commenced. There is little doubt that for small installations and for suitable waters when electrical current is available treatment with ultra-violet rays will be more economical than any other process yet devised, but it remains to be seen whether, under such circumstances, it will be able to compete with the chlorine process as now simplified and improved. It may be that under one set of circumstances one will be especially applicable, whilst under other circumstances the other will possess advantages. In any case it is no longer justifiable for any community to be supplied with water of a potentially dangerous character when by one or other of these processes potable waters can be practically sterilised and rendered safe at the cost of much less than a penny per 1000 gallons.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

An Alleged Custom of the Motor-car Hiring Trade.

IN a case recently heard by the Lord Chief Justice in the King's Bench Division the plaintiff sued a motor-car hiring company to recover damages for personal injury sustained through the alleged negligence of the defendant's chauffeur. It was alleged by the defence that the chauffeur was let with the car and became the servant of the hirer and not of the company, and that it was the custom of the trade that the hiring company took all risks, save and except liability for personal injuries to a person or persons hiring the car. The Lord Chief Justice, however, held that in such cases the chauffeur was the servant of the defendant, and that the company were liable for his negligence, if any, and that the alleged custom was of an extraordinary and most reaching kind. In the case in question, in which the car overturned as a result of excessive speed in taking a bend of the road, the plaintiff received a cut on the temple and other injuries, for which the jury awarded her £300 and costs. This case is certainly of interest, as it proves that when a car is hired with a driver the hiring company are liable for any accident the result of negligence on the part of the chauffeur.

The Ashcroft Combination Valve Grinder.

One of the most likely causes of loss of power in a motor is bad compression. If this is not due to gummed piston rings the valves are probably leaking. The former cause is easily diagnosed by pulling the starting handle round and listening, if needful with a stethoscope, for a hiss in the crank case. Should this not be detected, the conclusion, if the compression is bad, is pitted valves or leakage round the valve caps or sparking plugs. Placing oil round these parts and again pulling the engine round will reveal by the appearance of bubbles if the latter is the seat of lesion, and if not then the valves should be ground in. Fine emery or ground glass is usually employed, and the Ashcroft grinder will be found an improvement on the generally employed screw-driver. The action of this tool is an oscillating one, with the arc of oscillation gradually advancing to the right; this prevents the cutting of grooves, and results in the valve seat being ground smoothly and absolutely true. Two sizes of small coil springs are also supplied, which if placed under the valve head during the operation facilitate frequent raising of the valve and thus allow inspection as well as new grit and oil to run on the bearing surfaces; this renders the grinding more rapid while ensuring a better seat. The tool can also be used as a breast drill or as a ratchet for tapping and drilling, or for inserting or removing screws in awkward or inaccessible positions, and it is fitted with a chuck for either square or taper shank drills. It is sold by Messrs. Brown Brothers, Limited, of Great Eastern-street, London.

The Petrol Rebate.

In a recent number of *Justice of the Peace*, in answer to the question can a medical man, who obtains the allowance of half the duty on his car, be able to employ his automobile for other than professional purposes, the opinion was given that doing so would destroy the right to the exemption. This matter has now been brought to the notice of the Treasury, and the Lords Commissioners are of opinion that if a car is kept for the purposes of the profession it can be used for other purposes than merely conveying the doctor to and from his patients. Though this broad reading is pleasant, as far as it permits a doctor to take an occasional holiday in his car, it is well to bear in mind that a good many insurance policies do not cover risks that may occur when cars are employed for election purposes. For the present elections are over, while the experiences of some who have lent cars for them cannot be very pleasant.

The Automobile Association and the Motor Union.

The agreement for the amalgamation of these two bodies has now been concluded. The subscription will be £2 2*s.* a year, but members of the Motor Union who have not hitherto been members of the Automobile Association will be entitled to continue their subscription for a period of three years at the present rate of £1 1*s.* per annum. The badge is to be in the shape of the present Motor Union one, but in addition to the letter M with wings AA will also be in the centre. The Earl of Lonsdale will be President; Mr. Joynson-Hicks, chairman; Mr. Stenson Cooke, secretary; and Mr. A. B. E. Cheeseman, technical manager.

The Diagnosis of Clattering "Bruits."

The ability of analysing an adventitious noise in a car is much like "spotting" a cardiac lesion. The normal car has a steady quiet hum when running as our hearts have their "lubb-dup." When there is a variation it may mean the presence of some disorder, which, if not detected quickly, may have a serious termination. Among the causes that make a motor "talk" should be considered want of lubrication of bearings, both on engine and in gearbox and transmission shaft, slackness of nuts allowing play, and worn bearings. It should also be remembered that a loose mud-guard or even lamp may produce sounds that terrify; a slack undershield may have like results. The parts especially to investigate, if the engine begins to "talk," are: The clutch fork—is it worn? Does it rattle? Is the universal joint in the cardan shaft worn, or is the tort in the gearbox? Having eliminated rattling of kit or tools, lamps, lamp-brackets, and undershield, the engine should be run with the clutch out. If the sound is absent, it is probably either the clutch-fork, gearbox-bearing, or universal joint in the propeller shaft that is at fault.

Motor Road Maps.

The medical motorist who sends his name and address to Horlick's Malted Milk Company, Slough, Bucks, will be presented gratis with a set of three maps—England, Scotland, and Ireland, each in a separate case—on a 12 miles to an inch scale, showing the first- and second- class motoring roads and other roads, and the distances between the various towns.

The Adler Doctor's Car.

A good many professional men have asked me about this car, which attracted attention at the recent show, and concerning which I wrote in THE LANCET of Feb. 19th, 1910. My opinion of most automobiles on which I report is based on the result of the impression I obtain by running them a few hundred miles in the day or two during which they are at my disposal. The best proof of the use of a motor for a doctor is the actual results obtained by an owner during a prolonged period, when it is employed every day. The following letter, from Mr. Leslie, of "Fairwater," Evesham, may be of help to any who are considering the purchase of one of these really excellent machines:—

I think that a special word should be said for the 12-h.p. Adler as a car especially suitable for our work. Its reliability is truly marvellous and the class of workmanship is of the highest order. My two-seated 12-h.p. Adler with Morgan body I purchased in August, 1909, and during the time I have had it it has run close on 15,000 miles. I have not yet had an involuntary stop nor has a single adjustment had to be made, not even a nut has had to be tightened. The only renewal has been the brake jaws of the back wheel brake, which necessarily got worn from constant use. With the exception of this trifling replacement the car has not cost me a penny in repairs. On average roads I get 30 miles to the gallon. The car is practically silent on top speed and is the greatest pleasure to drive. Fitted with a Morgan body it is unusually smart; mine is of the semi-racing type. I have no hesitation in recommending the car to my professional brethren, and I do not think it could be excelled in reliability, general excellence, and cheapness in running.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

Distribution of Awards.

A MEETING of the Governors and General Council of King Edward's Hospital Fund for London was held on Dec. 14th at St. James's Palace, when the Duke of TECK presided.

His Serene Highness, in opening the proceedings, referred to the irreparable loss which the Fund had suffered by the death of its Founder and Patron, and in acknowledging, on behalf of himself, Lord Iveagh, and the Speaker of the House of Commons, their appointment as Governors of the Fund, expressed their intention to endeavour to follow the high tradition which had been established by the late King Edward and His present Majesty until the time came for the appointment of a new Royal President.

In the absence of Lord Rothschild (honorary treasurer), Lord REVELSTOKE reported that the amount received by the Fund to Dec. 10th, after payment of expenses, was £146,584 10*s*. The Fund had also received an unusual legacy during the year in the residue of the estate of Mr. Matyear, consisting of market garden property in Fulham.

Sir HENRY BURDETT said that at present he was not in a position to state precisely the sum that the League of Mercy would be able to give. When, however, the time arrived for drawing the cheque the Governors and Council of that Fund would, he believed, have good reason to be satisfied with the amount.

The Chairman of the Distribution Committee (Sir WILLIAM CHURCH) read the report of that committee. He stated that this year the sum of £150,000 would be distributed amongst the London hospitals, as against £147,000 in 1909. The number of hospitals applying for grants was 106, as against 104 last year. The committee recommended that the policy of setting aside grants towards amalgamation of the throat, nose, and ear hospitals in place of separate awards to any of the four institutions concerned should still be continued, and they voted £2000 this year for this purpose. No general scheme of amalgamation had been submitted by the hospitals during the year for the consideration of the Fund, and the committee would have recommended that the grant of £3000 made in 1908 should lapse in accordance with the condition attaching to grants which remain for two years unapplied, had they not been informed that the possibility of a practicable arrangement between certain of the hospitals was under consideration. They accordingly recommended that the grant of £3000 made in 1908 should be renewed for this year. The total sum held in reserve, in respect of annual grants, towards a general scheme of amalgamation now amounted to £7500 in addition to the capital grant, amounting under certain conditions to at least £10,000, promised by the Fund. The following grants made in 1908 for special purposes and retained in accordance with the practice of the Fund still remained unapplied:—General Lying-in Hospital, £100 to surgical equipment; London Lock Hospital, £1500, being the balance of a grant to the rebuilding of the out-patient department in Dean-street; Miller General Hospital, £989, being the balance of a grant to extension; West End Hospital for Diseases of the Nervous System, £1000, granted to rebuilding, subject to the scheme being submitted and approved; Wimbledon Cottage Hospital, £50 to improvements. The committee recommended that these unpaid grants should be renewed, with the exception of the grant to the West End Hospital, which it was recommended should lapse. The committee state that they have taken care that the needs of the poorer districts in the outlying parts of London should receive their due share of consideration. In addition to maintenance grants on the scale determined by the circumstances of the various hospitals, the committee have recommended capital grants in several cases where schemes of improvement have been sanctioned. Amongst these are final grants of £1000 to the rebuilding of St. Mary's Hospital for Women and Children, Plaistow, and £5000 to the extension of the West Ham Hospital.

The committee were glad to learn that a scheme had been prepared by the Convalescent Homes Committee for rendering a certain number of beds in consumption sanatoriums in the country available for patients direct from London hospitals, more especially from consumption hospitals which had no country branches of their own, and viewed with special satisfaction the facilities possessed by consumption hospitals which had country branches for the transfer of suitable cases to surroundings more favourable to recovery. In the case of St. George's Hospital "the committee had had under their special consideration the appearance, in the general accounts of the hospital for 1909, of certain payments to the school which were stated to be for work done for the hospital and which were formerly paid out of a discretionary fund. The inquiries made by the committee as to the legitimacy of this change confirmed the statement in the annual report of the hospital that the payments in question were made on account of definite work done, chiefly pathological and bacteriological examinations, in connexion with the actual treatment of patients. That is, the payments were for the kind of work which is described in Appendix III. of the Report of Sir Edward Fry's Committee as work which would have to be paid for in any case, and which would have to be taken into account in assessing the payments and receipts on either side.[1] Such work, moreover, differs entirely from the general benefits, described in paragraphs 13 to 22 of the report as being conferred by medical schools on hospitals, and as being fairly set off against the benefits conferred by the hospitals on the schools. The opinion of the Fund that, on the principles laid down by Sir Edward Fry's Committee, specific payments for such definite work done in respect of the treatment of patients, whether made to the school or to any other agency, could be charged to the general funds of the hospital, while no other payments to the school could be so charged, was notified to St. George's, in reply to a question from the hospital, by the Executive Committee in March, 1909. But on looking into the method by which the amount fairly chargeable to the hospital on account of this work had been arrived at, the Distribution Committee came to the conclusion that the apportionment of the expenses of the laboratories as between the treatment of patients and medical education required investigation, and they have invited the hospital to submit further details in order that the Committee may satisfy themselves that the payment made to the school bears a proper proportion to such definite work done for the hospital." In the meantime they recommend that the grant to the hospital this year should be retained until the Fund is satisfied that the financial relations between hospital and school are in accordance with the principles intimated by the Fund in March, 1909, and that the general account of the hospital in respect of 1909, as well as 1910, is clear from any payment on account of medical education.

Mr. WILLIAM LATHAM, K.C., chairman of the Convalescent Homes Committee, read the report of that committee. It showed that the sum of £5000 would be apportioned amongst convalescent homes and consumption sanatoriums. The amount distributed in 1909 was £4000, which included £1000 brought forward from 1908. The number of applications eligible for consideration amounted to 45 from convalescent homes and 8 from consumption sanatoriums, as against 37 and 4 respectively last year. The committee reported that they had been able to make arrangements in the case of three sanatoriums for beds to be placed at the disposal of London hospitals during the year 1911 in return for grants made by the Fund. The total number of beds thus secured amounted to 18, situated as follows: 2 beds at the Kelling Sanatorium, Norfolk; 6 beds at the Northampton Sanatorium, Creaton, Northants; and 10 beds at the Devon and Cornwall Sanatorium, South Brent, Devon. In recommending the allocation of these country beds to hospitals in London the committee had taken the view that preference should be given (in order of relative size) to the two consumption hospitals which had no country branches, and that the rest of the beds should be divided between the two largest of the general hospitals which apply to the

[1] The following is an extract from this appendix, which the committee have adopted as part of their report:—"It must be remembered that, apart from these (i.e., the general services rendered by the Schools to the Hospitals), which are separately dealt with in the Report, par. 21, the Schools, in most cases, undertake many specific laboratory examinations solely for the purpose of helping the physicians and surgeons to form correct diagnoses in the exclusive interests of the patients, and that these would have to be paid for by the Hospitals in any case. Where such examinations are made in a laboratory entirely maintained by a school, it is obvious that, in any exact assessment of the payments and receipts, on either side, they would have to be taken into account."

Fund. They accordingly recommended the following allocation: 8 beds to the City of London Hospital for Diseases of the Chest, 4 beds to the Royal Hospital for Diseases of the Chest, 3 beds to the London Hospital, and 3 beds to Guy's Hospital.

The Duke of TECK, in moving the adoption of the reports and awards, said that the reports afforded gratifying evidence of the continued progress of the Fund. The invested capital was now very considerable, but the income from investments provided less than half the amount distributed, and for the balance reliance had to be made upon the support of the charitable public, including the contributions collected by the League of Mercy. Among the amounts received during the year His Serene Highness mentioned, with special gratitude, the sum of £500 received from His Majesty, the patron of the Fund, in augmentation, from £500 to £1000, of the annual subscription he gave when President; and also the annual subscription of £100, with which H.R.H. the Prince of Wales had signified his interest in the Fund. The receipts also included an annual subscription of £5000 from Mr. Walter Morrison, and an anonymous donation of £10,000. The amount distributed had again been increased. Last year it reached, for the first time, a total sum of £150,000. This year £150,000 had been given to the hospitals alone, making, with £5000 to consumption sanatoriums and convalescent homes, a total of £155,000. The original goal of £150,000 had thus been left behind, and in response to the necessarily increasing demands a fresh advance had been begun. He particularly drew attention to the grants for special purposes. In practically every case, he said, where such a grant was at all large a scheme had been submitted by the hospital and carefully examined by the committee. This practice ensured that the Fund knew and approved of the manner in which the grant was going to be spent. Referring to questions that had arisen during the past two years as to the exact method of applying the recommendations of Sir Edward Fry's committee on the subject of hospitals and medical schools, His Serene Highness said it was, and had always been, the intention of the Fund to carry out the recommendations of that committee in the letter and in the spirit. The report of the Convalescent Homes Committee showed that the scheme which they originated for placing beds at consumption sanatoriums by means of grants from the Fund, at the disposal of patients in London Hospitals who were urgently in need of country treatment, had now taken practical shape. A beginning could be made on Jan. 1st next, with 18 beds in three different sanatoriums. It was proposed that most of these beds should be allotted to the two consumption hospitals which had no country branches of their own, and the remainder to two of the largest general hospitals. It was not possible to secure any more beds without making capital grants. But the committee proposed to consider applications for capital grants another year. If the scheme on its present small scale proved successful, it could be thus enlarged. The committee would, of course, take due precautions to ensure that any arrangement made should be fair to London, while the sanatoriums would doubtless see that it was fair to the localities for which they were originally founded.

The work of the Executive Committee had included this year a consideration of the question of hospital contracts. It had often been suggested that it would be an advantage for the hospitals of London to enter into joint contracts, and thus secure the advantages of purchasing on a larger scale than they could do as separate buyers. Last year a scheme was actually started in New York, and the Executive Committee appointed a subcommittee to inquire into the subject and ascertain whether the Fund could usefully take any action in the matter. The report of this subcommittee, of which Mr. John G. Griffiths acted as chairman, had recently been issued, and he hoped that the careful statement which it contained of the possible advantages and difficulties of coöperative purchase by groups of independent voluntary hospitals might be of assistance to the hospitals which were now trying this experiment, or which might be thinking of doing so; and that it might satisfy the public that the possibilities of economy in this direction had not been overlooked.

The CHIEF RABBI (the Rev. Dr. ADLER) seconded the adoption of the reports, which was put and carried.

The Duke of TECK, before announcing the appointments for the coming year, alluded to the great loss the Fund had sustained during the year in the death of Mr. Hugh C. Smith, who had served for so many years as a trustee, member of the council, chairman of the Executive Committee, and latterly member of Finance Committee, and also to the loss by death of the very valuable services of Mr. John Langton as one of the visitors of the Fund. With regard to the general council, it was proposed to reappoint the whole of the members as at present, and the same with the Executive Committee and the Finance Committee. On the Distribution and Convalescent Homes Committees it was proposed to reappoint the present members except Mr. Partington, who had been prevented by ill-health from taking a full share in the very arduous work of the Distribution Committee. He would join the Convalescent Homes Committee, as would also Sir William Bennett, and Mr. Leonard Cohen would be appointed to the Distribution Committee.

The services of three eminent Commissioners—Lord Mersey, who would be chairman, Lord Northcote, and the Bishop of Stepney—had been secured for the committee which would inquire into the out-patient question and would begin work early in 1911. The Executive Committee had recommended the following terms of reference:—

> To consider and report generally as to the circumstances and conditions under which patients are admitted to the casualty and out-patient departments of the London voluntary hospitals, and especially as to what precautions are taken to prevent the admission of persons who are unsuitable, and as to whether adequate provision is made for the admission of such persons as are suitable; and to make such recommendations as may seem to them desirable.

A vote of thanks to the Duke of Teck for presiding concluded the proceedings.

MEDICINE AND THE LAW.

Tuberculosis and Milk-supply: Question of Procedure raised at Sunderland.

AT Sunderland recently an inquiry was held by Mr. T. R. Colquhoun Dill, barrister-at-law, on behalf of the Board of Agriculture and Fisheries, to whom a farmer had appealed against an order made by the Sunderland corporation. The appellant supplied milk to a dairy in Sunderland, as did other farmers also. A sample of milk was taken in the street by an inspector under the corporation from a can belonging to the dairy in question and was found on analysis to contain the bacilli of tuberculosis. The dairyman stated that the milk from which the sample in question came was from the appellant's farm, and it was accordingly visited by the medical officer of health of the corporation, who was accompanied by a veterinary surgeon. The farmer owned a herd of 20 cows, from whose milk he supplied the dairy, and 16 of these had already been submitted to the tuberculin test with negative results. The remaining four had not been so tested, and the veterinary surgeon, who detected in three of them no signs of tuberculous disease, observed what he considered to be suspicious indications affecting the udder of the fourth. The corporation, which was acting upon powers given it by a local Act of Parliament obtained by the borough of Sunderland in 1907, gave notice to the farmer to appear before its health committee, and when he did not do so made an order prohibiting the sending of the milk of any of the four cows referred to above into the borough. The farmer then had the tuberculin test applied in the case of the cow with the suspected udder, when it was found that there was no reason to believe that she was affected with tuberculosis. This he communicated to the corporation, which rescinded the order, so far as it affected the cow in question, leaving it as before in the case of the other three; and against the order, as applied to them, the farmer appealed. It was argued upon his behalf before Mr. Dill that the procedure adopted was wrong, as it cast upon the farmer the burden of proving that the three cows remaining under the order were free from tuberculosis, without the corporation having first made out a *primâ facie* case that they were diseased. It was pointed out that the Act under which the proceedings had been taken gave power to inspect the cows and to take samples of milk, and it was submitted that if after this the medical officer of health was of the opinion that tuberculous disease was caused, or likely to be caused, to persons residing in the borough and consuming the milk, a notice might then be served on the owner of the cows to

attend before the health committee to show cause why an order should not be made prohibiting him from supplying milk in the borough. A notice had, as has been stated, been given to the farmer, who had not appeared in response to it, and it was argued on his behalf that the necessary conditions precedent to giving it and to making the order had not been fulfilled. On behalf of the respondents it was argued that they had complied with the Act of Parliament, and had made an entry upon the farmer's premises and an inspection as required of them upon an order obtained from a magistrate, but that a passage in the Act, to which Mr. Dill drew the attention of the town clerk, which provides that "the medical officer of health may require" a cow to be milked in his presence and a sample to be taken for analysis, merely permitted this to be done, but did not render it necessary. It was urged that the corporation as custodian of the public health, was entitled to act as it had done, and if it entertained a suspicion with regard to the three cows to continue its order against them until the appellant had shown that the animals were free from disease. After hearing the arguments and evidence adduced by both sides, Mr. Dill intimated that he would report to the Board of Agriculture and Fisheries and that the reply of the Board would follow in due course. The decision of the Board of Agriculture and Fisheries has since been communicated to the parties, and is to the effect that the order of the corporation was made without due cause in so far as it related to the three cows in question. The Board further found that the appellant was not in default and withdrew the order made against him, the costs of the appeal to be paid by the corporation.

Action against a Farm Colony for the Loss of a Leg.

A German named Max Wedler brought an action recently in the High Court against the council and committee of management of a German Industrial and Farm Colony at Ware for damages for negligence and breach of duty on their part. He had been admitted to the colony and set to perform some digging after being supplied with shoes. He stated that he complained of these that they were too large, but was compelled to wear them and was refused permission to wear his own, that while he was digging, earth got into the shoes and chafed his foot, and that on his informing Mr. Mann, the manager, he was sent by him to a man called Theil, stated to be a "pensioner" in connexion with the colony, who gave him a plaster. Theil also told him that he was suffering from gout and massaged his foot. Later, the plaintiff become seriously ill, but according to his statement, a medical man who was called in to see him did not examine his foot. Eventually he was sent to the Herts County Hospital, where it was found that he was suffering from osteomyelitis, owing to which his leg was amputated below the knee; and the nature of the case was explained to the jury by Dr. C. E. Shelly, senior medical officer of the hospital. The same witness expressed the opinion that an abrasion of the skin such as that described would supply a very obvious means for the infection which had taken place. Counsel on behalf of the plaintiff contended that he had two causes of action—the neglect by the defendants of a duty to supply him with clothing reasonably suited for the work he had to do, the evidence being that the shoes were too large and were responsible for the injury which caused his condition; and, secondly, the treatment given by Theil. Counsel for the defence did not rely upon the defence of common employment on the part of the plaintiff and Theil, but submitted that apart from that there was no case for the defendants to answer. This view was taken by Mr. Justice A. T. Lawrence, who held that there was no evidence of negligence against the defendants; there might possibly be a case against Mann and Theil, who might, however, have an answer to it. Judgment was accordingly given for the defendants without the case being submitted to the jury.

A RAILWAY MEDICAL SCHOOL IN MANCHURIA.—We learn from a Shanghai correspondent that the South Manchurian Railway Company is contemplating the establishment of a medical school at Dairien, Manchuria, where instruction will be given in all the most modern methods of medicine and surgery.

CENTRAL MIDWIVES BOARD.

SPECIAL meetings of the Central Midwives Board were held on Dec. 13th and 15th, at Caxton House, Westminster, Sir FRANCIS H. CHAMPNEYS being in the chair.

The Board considered the following charges, amongst others, against the midwives whose names are given below, and ordered them to be struck off the roll. For not explaining that the case was one in which the attendance of a registered medical practitioner was required, nor handing to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 19 (5):—Margaret Aldred, being in attendance as a midwife at a confinement, the child having been born prematurely, and being asphyxiated and feeble. Hannah Arrowsmith, being in attendance as a midwife at a confinement, the patient suffering from headache and sickness and from high temperature. Ellen Culshaw, being in attendance as a midwife at a confinement, the patient being ill, suffering from abdominal pains and high temperature, with diarrhœa and vomiting. Sarah Chapman, being in attendance as a midwife at a confinement, rigor occurring with persistently offensive lochia and a high temperature. Mary Hannah Davis, being in attendance as a midwife at a confinement, the child being ill. Mary Jane Dickenson, the patient suffering from bronchitis. Adelaide Harker, being in attendance as a midwife at a confinement, the child suffering from inflammation of the eyes. Kate Martin, being in attendance as a midwife at a confinement, the patient suffering from a serious rupture of the perineum. Mary Ann Miles, being in attendance as a midwife at a confinement, the child suffering from inflammation of the eyes. The following were also struck off the roll for the reasons given in each case:—Martha Holland, that she was convicted at the Oxford City police-court of having been found drunk and incapable on a public highway. Beatrice Inscoe, that she persistently refused to submit to the reasonable supervision and inspection of the local supervising authority or to conform to the rules of the Board, and with intent to evade such supervision and inspection she frequently changed her address without notifying the local supervising authority as required by Rule E. 20. Emily Jones, that being in regular attendance as a nurse upon a patient suffering from uterine cancer, she nevertheless carried on her practice as a midwife, contrary to the provisions of Rule E. 16, and without having undergone disinfection to the satisfaction of the local supervising authority as required by Rule E. 5. Marian Phillis McCormac, that being in attendance at a confinement she was under the influence of alcohol when she delivered the patient; after the delivery of the placenta she failed to remove it from the room as required by Rule E. 10, but left it under the bed until next day; and she was again under the influence of alcohol and unable to speak clearly when she visited the patient on the seventh day after the confinement. Edith May Dalchow, that at the Aylesbury petty sessions she pleaded guilty to a felony and was sentenced to one month's imprisonment. Sarah Susannah Emptage, that being in attendance as a midwife at a confinement she failed to adopt the antiseptic precautions required by Rules E. 3 and 7; she washed the baby's eyes with the water it had been bathed in, she washed the patient with the same water and rag as she had used for the baby, and she did not take the patient's temperature at any time. Sarah Flitton, that being in attendance as a midwife at a confinement she did not take any antiseptic precautions whatever; she was uncleanly in her person, house, and clothing; she never employed antiseptics, being ignorant of how to use them; and she never took the temperature of her patients, not understanding the use of a clinical thermometer. Elizabeth Jane Haines, that she persistently neglected to make herself acquainted with the obligations of the rules of the Board. Julie Mitchell, that she was irregular in her attendance on her patients during the lying-in period, and that she persistently failed to conform to the directions of the local supervising authority. Amelia Williams and Mercy Ann Wilson, that notwithstanding repeated warnings they neglected and refused to comply with the rules of the Board and the directions of the local supervising authority. Catherine Charlton, that being in attendance as a midwife at a confinement she entered in her register that two children were

full time and of good health, well knowing that these statements were false, and that one child had died two days before the date of the entry. Esther Green, that being in attendance as a midwife at a confinement she took the patient's temperature once only, and failed to attend to the cleanliness and comfort of the patient as required by Rule E. 11. Elizabeth Murray, that being in attendance as a midwife at a confinement she falsely entered in her register of cases that the condition of the mother on the date of her last visit was "moderate," whereas she was dead.

The following were censured after charges against them had been considered:—Jane Carroll, Sarah Dean, Sarah Bath, Sarah Elizabeth Brown, Ellen Gentle, Martha Howard, Alice Waters, and Barbara Young.

The following were cautioned after charges against them had been considered:—Emma Gleeson and Sarah Linton.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: E. B. Townsend and F. D. Lumley to the *President*, for three months' course of hospital study; H. W. Finlayson to the *Victory*, for R.N. Barracks; E. J. Finch to the *Blake;* and C. S. Facey to the *Warrior*. Staff-Surgeons: J. A. Forrest, H. R. Gardner, N. J. Roche, P. G. Williams, J. G. Peebles, and W. E. Gribbell to the *President*, additional, for three months' course of hospital study; C. J. E. Cock to the *Thames;* O. Rees to the *St. George;* J. K. Raymond to the *Foresight*, A. K. Smith-Shand to the *Natal;* H. H. Pearse, L. E. Dartnell, S. Conner, R. Waterfield, G. E. Macleod, and F. C. B. Gittings, to the *President* for three months' course of hospital study; and J. Thornhill to the *Vivid*. Surgeons: C. H. Dawe to the *Pembroke;* S. H. Vickers to the *King Alfred;* J. A. Thompson to the *Pembroke;* F. M. V. Smith, E. B. Kenny, L. C. E. Murphy, and H. B. German to the *President*, for three months' course of hospital study; and G. R. McCowen to the *Victory*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. H. Hall, from Colchester, has been appointed Senior Medical Officer at Bermuda, in succession to Colonel J. C. Culling, who has taken up duty as Principal Medical Officer of the Western Command at Chester. Lieutenant-Colonel G. Cree, on arrival home from India, has been posted to the Eastern Command and appointed Medical Inspector of Recruits, vice Lieutenant-Colonel G. E. Hale, D.S.O. Lieutenant-Colonel J. Maher, from Wynberg, has been appointed to the medical charge of Queen Alexandra's Military Hospital, Grosvenor-road. Lieutenant-Colonel F. W. C. Jones, from Tidworth Park, has embarked in the transport s.s. *Plassy* for a tour of service in India. Lieutenant-Colonel J. R. Forrest has been transferred from Bullevant to Cork. Lieutenant-Colonel W. G. Birrell has taken over medical charge of the Royal Herbert Hospital at Woolwich, in succession to Lieutenant-Colonel W. Dick. Major H. Herrick has been appointed to the command of the Station Hospital, Hyderabad, Sind, vice Captain P. P. O'Keefe, who has been transferred to the Station Hospital at Roorkee. Major G. B. Stanistreet, from Salisbury, has been posted to the London District. Major F. J. C. Heffernan, on completion of a tour of service in India, has been appointed Recruiting Medical Officer, London District. Major G. A. Moore has been placed in medical charge of the Military Families Hospital at Chatham. Major H. V. Prynne has been appointed Medical Officer at the Royal Military Academy, Woolwich. Major W. B. Winkfield, Captain C. H. Furnivall, and Captain G. F. Rugg have embarked on the transport s.s. *Plassy* for a tour of service in India. The following officers (Captains) have joined at the Royal Army Medical College for a course of instruction for promotion to the rank of Major: W. Wiley, H. Harding, M. F. Grant, M. D. Ahern, H. C. Winckworth, R. J. B. Buchanan, H. H. A. Emerson, A. M. Rose, P. Farrant, C. J. Wyatt, and M. G. Dill. Captain A. M. MacLaughlin has been appointed Specialist Sanitary Officer to the Scottish Command. Captain W. M. B. Sparkes has been placed in Medical Charge of the Staff and Departments at Dublin. Captain J. W. West, Captain S. M. Adye-Curran, and Captain J. H. Spencer have arrived in India for duty. Captain T. S. Coates has been appointed Medical Officer at the Royal Arsenal, Woolwich. Captain W. D. C. Kelly has taken over the duties of Specialist in Advanced Operative Surgery at Dublin. Captain E. J. H. Luxmoore, on arrival home from India, has been posted to the Eastern Command. Lieutenant A. G. Jones, from Parkhouse Camp, has joined at Tidworth Park. Lieutenant H. G. Robertson has been transferred from Sheffield to Richmond.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel H. B. Melville, civil surgeon of Simla, has been appointed to the medical charge of the Army Headquarters Staff and Establishments during the absence of Captain A. E. Lister. Lieutenant-Colonel F. J. Dewes, civil surgeon at Shwebo, has been granted combined leave and furlough home from India for two years. The services of Lieutenant-Colonel J. A. Cunningham, civil surgeon at Lahore and professor of forensic medicine and toxicology at the Medical College, Lahore, have been placed at the disposal of the Government of India. Lieutenant-Colonel D. St. J. D. Grant has been appointed to officiate as Principal Medical Officer of the Sirhind and Jullundur Brigades in succession to Lieutenant-Colonel J. W. Rodgers. Lieutenant-Colonel A. L. Duke has been confirmed in his appointment as First-class Agency Surgeon and Administrative Medical Officer of the North-Western Frontier Province. Major W. Lethbridge, civil surgeon of Wana, has been appointed by the Foreign Department of the Government of India Agency Surgeon, Mewar Bhil Corps, vice Captain L. J. M. Deas, proceeding on leave. Major H. A. Smith, civil surgeon of Agra, has been nominated as an Ordinary Fellow of the Allahabad University. Major F. L. Blenkinsop has had his leave extended by six months on medical certificate. Major J. M. Crawford, on return from leave, has been appointed Civil Surgeon at Benares. Captain R. M. Carter, Captain J. P. Cameron, Captain L. J. M. Deas, and Captain M. J. Quirke have arrived home from India on leave. Captain S. R. Godkin has been appointed Specialist in Advanced Operative Surgery to the Sixth (Poona) Division. Lieutenant M. A. Nicholson has embarked for India in the transport s.s. *Plassy* from Southampton.

BRITISH RED CROSS SOCIETY.

At a meeting of the City of London branch of the British Red Cross Society, which was held at the Mansion House on Dec. 16th under the presidency of the Lady Mayoress, it was reported that at the Prudential Assurance Company most successful classes had been established, and 115 of the men members of the staff and 46 of the lady members had already passed the first-aid examinations, and 42 other ladies were waiting to hear the result of their examinations. After the Christmas holidays it was expected that similar classes would be started in other City establishments.

ARMY AND NAVY MALE NURSES' CO-OPERATION.

A meeting of this association was held at the Royal Horticultural Hall, Westminster, on Dec. 16th, when Colonel Sir Edward Ward presided. He said that it was not generally realised that the army and navy were the only general training schools which certified fully-trained male nurses. Every year the services discharged fully-qualified nurses of exemplary character, whose training had been costly, and who, until the co-operation was founded, drifted into unsuitable channels where their skill found no market value. To give these men a start in life it was only necessary to make their professional nursing merits known. Sir William Allchin and Surgeon-General W. Babtie, V.C. (Deputy Director-General), also addressed the meeting, after which a bazaar and people's bargain sale was opened by Mrs. George Alexander.

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1910.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·0 per 1000 of the population, estimated at 4,872,702 persons in the middle of the year. In the three preceding months the rates were 3·9, 5·3, and 5 9 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington,

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

the City of Westminster, St. Marylebone, and Stoke Newington; and the highest rates in Islington, Finsbury, Poplar, Bermondsey, Deptford, and Woolwich. The prevalence of scarlet fever showed a marked decline from that recorded in the previous month; among the several metropolitan boroughs this disease was proportionally most prevalent in St. Pancras, Poplar, Bermondsey, Battersea, Deptford, Lewisham, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals at the end of the month was 1727, against 1439, 1630, and 1825 at the end of the three preceding months; the weekly admissions averaged 183, against 160, 207, and 229 in the three preceding months. Diphtheria was rather less prevalent than it had been in October; the greatest proportional prevalence of this disease was recorded in Hammersmith, Fulham, Chelsea, Islington, Finsbury, the City of London, and Bermondsey. The Metropolitan Asylums Hospitals contained 866 diphtheria patients at the end of last month, against 580, 746, and 852 at the end of the three preceding months; the weekly admissions averaged 106, against 76, 108, and 120 in the three preceding months. The prevalence of enteric fever showed a considerable decrease from the somewhat excessive figures for the two preceding months; among the several metropolitan boroughs this disease was proportionally most prevalent in Hackney, Finsbury, Bethnal Green, Stepney, Southwark, Bermondsey, and Lambeth. There were 134 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of November, against 58, 141, and 169 at the end of the three preceding months; the weekly admissions averaged 16, against 32 and 25 in the two preceding months. Erysipelas was proportionally most prevalent last month in Hackney, Finsbury, Bethnal Green, Stepney, Poplar, and Deptford. The 29 cases of puerperal fever notified during the month included 3 in Hackney, 3 in Stepney, 3 in Lambeth, and 2 each in Kensington, Poplar, Battersea, and Wandsworth. The 4 cases of cerebro-spinal meningitis notified during the month belonged respectively to Paddington, St. Marylebone, Shoreditch, and Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates are further corrected for variations in the sex and age constitution of the populations. During the five weeks ending Dec. 3rd the deaths of 7742 London residents were registered, equal to a corrected annual death-rate of 17·4 per 1000, the rates in the three preceding months having been 10·3, 11·9, and 12·6 per 1000 respectively. The death-rates last month ranged from 11·3 in Hampstead, 12·1 in Lewisham, 12·8 in Wandsworth, 13·1 in Greenwich, 13·4 in the City of London, 13·6 in Chelsea, and 13·7 in Woolwich, to 20·5 in Poplar, 21·2 in Shoreditch, 22·1 in Bethnal Greeen, 23 3 in Southwark, 23·7 in Finsbury, and 24·9 in Bermondsey. The 7742 deaths from all causes included 672 which were referred to the principal infectious diseases; of these, 409 resulted from measles, 21 from scarlet fever, 56 from diphtheria, 45 from whooping-cough, 23 from enteric fever, and 118 from diarrhœa. No death from any of these infectious diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest rates in Chelsea, the City of Westminster, Hampstead, Wandsworth, and Lewisham; and the highest rates in Hammersmith, Islington, Finsbury, Shoreditch, Southwark, Bermondsey and Camberwell. The 409 deaths from measles were more than three times the average number for the corresponding period of the five preceding years; this disease was proportionally most fatal in Hammersmith, St. Pancras, Islington, Finsbury, Shoreditch, Southwark, Bermondsey, and Camberwell. The 21 fatal cases of scarlet fever showed a decline of 36 from the corrected average number, and included 3 in St. Pancras, 3 in Poplar, 2 in Stepney, 2 in Battersea, and 2 in Lewisham. The 56 deaths from diphtheria were 25 below the corrected average number; the greatest proportional mortality from this disease was recorded in Hammersmith, Finsbury, Bethnal Green, Southwark, and Bermondsey. The 45 fatal cases of whooping-cough showed a decrease of 29 from the corrected average number; the highest death-rates from this disease last month were recorded in Hammersmith, Fulham, St. Pancras, Finsbury, Shoreditch, Bethnal Green, Bermondsey, Battersea, and Woolwich. The 23 deaths from enteric fever were 8 below the corrected average number; of these 23 deaths, 4 belonged to Lambeth and 2 each to the City of Westminster, Islington, Hackney, Bethnal Green, Battersea, and Wandsworth. The 118 deaths from diarrhœa were 33 fewer than the corrected average number; this disease was proportionally most fatal in Paddington, Stoke Newington, Finsbury, Bethnal Green, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 27·4 per cent. above the average.

LAVATORY ACCOMMODATION FOR WOMEN.

To the Editor of THE LANCET.

SIR,—I desire to bring to your notice the accompanying resolutions which were passed at a conference of representatives of the following bodies on Nov. 21st:—The Royal Sanitary Institute, the National Health Society, and the Women's Imperial Health Association. Mrs. Oxley Grabham, who has conducted an extensive investigation into the sanitary accommodation provided by railway companies for women, was also present.

With regard to resolution No. 1 it may be said that although the system now so largely adopted by the railway companies of providing lavatory carriages on long-distance trains, has proved an enormous benefit to both men and women travellers, still there is considerable evidence that the accommodation for women at railway stations all over the country is often insufficient and insanitary, whilst the necessity for payment, which is still universal for women at railway stations, operates harshly on the travelling public of the more necessitous classes.

Appropriate communications have been addressed on the subject of the aforesaid resolutions to the Local Government Board, the Board of Trade, the London County Council, and the principal railway companies, and the conference desires to enlist the powerful aid of THE LANCET in making the resolutions known to its readers, or in any other way helping a reform which is so intimately associated with the health and comfort of the female members of the community.

I am, Sir, yours faithfully,

LOUIS C. PARKES,
Chairman of Council, the Royal Sanitary Intitute.

London, S.W., Dec. 16th, 1910.

[RESOLUTIONS.]

1. That in the opinion of this meeting sufficient sanitary accommodation for women's use should be provided free of charge by sanitary authorities, railway companies, and in places of public entertainment and resort.
2. That in the opinion of this meeting it is essential in the interests of public health and decency that there should be an attendant in charge of the sanitary convenience provided for women's use in public places.
3. That in the opinion of this meeting all sanitary conveniences provided for the use of women should be subject to periodical inspection by women sanitary inspectors appointed by the local sanitary authorities.
4. That this meeting desires to call the attention of the railway companies, and managers of theatres and other places of public resort, to the unsatisfactory character of much of the sanitary accommodation provided for women, and to the necessity for having only sanitary conveniences of good modern type and construction.

THE POSITION OF HOMŒOPATHY.

To the Editor of THE LANCET.

SIR,—The appreciative and sympathetic references recently made by the press to the death of my old and valued friend, Dr. Dyce Brown, whose ability, amiability, and keen artistic sense had won for him the affection and respect of a wide circle, must have made others besides myself think whether it is not time to reconsider our attitude towards homœopathy. The objections to that method of treatment, so far as I understand them, are based on the belief that its professors are practising what they do not believe, and are therefore guilty of a grave breach of the moral law, in consequence of which they are scorned

and rejected of men, boycotted in medical circles, excluded from hospital appointments, and practically from social intercourse with their brethren. It is not likely that respectable people honestly trying to do their duty according to their lights should feel anything but sore when they are thus branded with the mark of Cain, and a bitter feeling has thus grown up between the two equally qualified sections of medical and surgical science, which, I venture to think, is little creditable to ourselves. For what great crime, after all, have the homœopathists committed? The absurd doctrines of Hahnemann have long since been abandoned, and all that they now do is to treat disease on a much more scientific principle than ours, by often-repeated doses of strong tinctures instead of the nauseating tablespoonfuls and wineglassfuls which too often nauseated the patient and retarded his chances of recovery. I have no doubt that Sir Richard Quain lost the Presidentship of the Royal College of Physicians of London, which he had fairly earned by earnest and successful work, because he met Dr. Kidd in consultation over Lord Beaconsfield's case, and I well remember the storm in a tea-cup which ruffled the calm waters of Pall Mall, when an attempt was made to "run in," or rather "run out," Dr. Murrell and Professor Ringer for an alleged therapeutic heresy, an attempt which properly and ignominiously failed. I suppose my professional brethren are too much beaten down by the authority of the Royal Colleges to air their views.

I am, Sir, yours faithfully,

Finzean, Dec. 19th, 1910. R. FARQUHARSON.

THE MOTOR FUNCTIONS OF THE STOMACH.

To the Editor of THE LANCET.

SIR,—In his letter of Dec. 17th Mr. Gray excuses himself for ascribing Bayliss and Starling's discovery of secretin to Wertheimer, who had nothing to do with it, by saying that in the same paragraph "an extensive quotation, duly ascribed to Starling, appears." However gratifying this must have been to Professor Starling, a quotation from a discussion by Starling on some observations made by Edkins (who is not mentioned by Mr. Gray) hardly compensates for giving the credit of Bayliss and Starling's epoch-making discovery of secretin to "Wertheimer and others."

With regard to Mr. Gray's "recent radiographers and others," who "assert that the pylorus during gastric digestion descends naturally below and to the left of the umbilicus," I think that Mr. Gray must have misunderstood Dr. Barclay's references to the work of Pfahler and Holzknecht instead of referring to their original papers. Dr. Barclay will doubtless reply to Mr. Gray himself, so that I shall content myself with quoting from Pfahler and Holzknecht. According to Pfahler,[1] the pylorus is "usually about an inch above the umbilicus," and "the pyloric portion extends from one to two inches beyond the median line to the right," and Holzknecht[2] states that the pylorus is above the umbilicus and "lies in front of or to the right of the spinal column." The figures given in Pfahler and Holzknecht's papers as types of what they regard as normal stomachs bear out this description. The disagreement between various radiographers as to what is the "normal" stomach is simply a matter of terminology. Barclay, Rieder, Holzknecht, and Pfahler all agree as to the shape of the stomach most commonly seen in healthy people, but while Barclay and Rieder think that this shape should be regarded as the normal, Holzknecht and Pfahler think that the "ideal" form, in which the greater curvature does not reach below the umbilicus and the pylorus is on a level with the lowest point of the organ, should be regarded as normal, although they admit that it is comparatively rarely seen.

Our disagreement as to the occurrence of peristalsis in the "cardiac end" of the stomach is, I expect, simply due to a misunderstanding as to nomenclature. Peristaltic waves generally begin near the junction between the upper and middle thirds of the stomach; this point lies in what Cunningham, following His, called the "body" of the stomach, and corresponds probably to what Mr. Gray calls "the distal part of the cardiac portion," which seems to me to be a less convenient term. Mr. Gray apparently believes that these waves at first pass no farther than his "third sphincter," whilst physiologists and radiographers agree that they pass without interruption to the pylorus.

Why does Mr. Gray think that food may pass directly into the duodenum in infants, but only after a considerable delay in adults? I can only imagine that it is because it is easier to observe the process through the small, and therefore more transparent, bodies of infants than through the more opaque bodies of adults. I have watched food (and by food I mean *food*, and not water or albumin water) enter the duodenum immediately after a meal has been taken in a very large number of cases, and any afternoon that Mr. Gray calls at Guy's Hospital I am sure that Dr. A. C. Jordan, our medical radiographer, will be pleased to demonstrate this to him in as many cases as he may desire.

If Mr. Gray thinks that the pylorus requires "at least a little free hydrochloric acid before its sphincter action is unloosened," how does he account for the fact that, according to all writers on this subject, the stomach empties itself with undue rapidity in primary achylia gastrica? In this condition, as well as in almost all cases of carcinoma of the stomach, in nearly all cases of pernicious anæmia, and in many of simple gastritis, free hydrochloric acid is present at no period during digestion, so that the pylorus should never relax and its contents never leave the stomach, if Mr. Gray were correct.

Even if Dr. Barclay disagrees with me as to the position of the pylorus, which I doubt, by what process of reasoning does Mr. Gray conclude from this that Barclay's observations on duodenal ulcer, which are in complete agreement with mine, should not be accepted as confirmation of mine? Our observations prove that the late onset of pain is not due to food being held back by the pylorus or by Mr. Gray's "third sphincter," as we both have found that the food passes into the duodenum with unusual rapidity in cases of duodenal ulcer. The true cause of hunger pain hardly comes within the scope of a discussion on the "motor functions of the stomach."

I am, Sir, yours faithfully,

Weymouth-street, W., Dec. 17th, 1910. ARTHUR F. HERTZ.

ORGANIC PREPARATIONS OF ARSENIC.

To the Editor of THE LANCET.

SIR,—It would be a striking confirmation of the truth of Goethe's admonition, "Warum in die Ferne schweifen, sieh das Gute liegt so nah," were it now to be shown that what is practically our oldest organic preparation of arsenic, introduced into therapeutics 46 years ago by a now forgotten German physician, exhibits the same action on spirochætæ as the recently evolved complicated compound of another compatriot.

Cadet in 1760 obtained a fluid by distilling a mixture of arsenic and potassium acetate; this was known under the designation of Cadet's fluid, alkarsin, or fluid pyrophore. Bunsen, in 1837, first analysed this fluid, and found that it consisted principally of cacodyle and cacodyle oxide, which could be converted into cacodylic acid by oxidation. The first pharmacological experiments with this preparation were undertaken by Bunsen himself on frogs, and by Kürschner on rabbits. The latter found that a dose of 0·42 gramme could be given intravenously without harm; indeed, one animal bore this dose following the administration per os of a dose of 0·36 gramme. In 1843 it was therefore already established that cacodylic acid was non-toxic. In 1860 Schmidt and Chomse confirmed the above statement regarding the non-poisonous character of cacodylic acid, but they found that under certain circumstances it was reduced in the stomach. Lebahn, in 1868, stated that it possessed the action of arsenic, but that it was considerably less toxic than the latter or its salts. Schulz (1879), Marshall and Green (1886) were also able to confirm the above statements; in other words, as far back as 1886 no less than eight authors had published the results of their physiological and pharmacological investigations of cacodylic acid. Jochheim was the first to try the use of cacodylic acid in his practice in 1862, and he published at the time a report of the excellent results he had obtained from its use in the treatment of chronic skin diseases and pulmonary tuberculosis. I recently came across a now forgotten publication of his which bears the date 1865 and is in the possession of the Grand Ducal Court Library here. In this work he says that in his opinion

cacodylic acid exhibits so prompt an action in pulmonary tuberculosis because "it imparts to the blood of the patient a condition which is inimical to the tuberculosis." In my opinion, this is a very interesting statement, especially when we bear in mind that this was long before Koch's discovery or before anything was known about antibodies, antitoxins, and side-chain theory. Between Jochheim in 1862 and Gautier in 1899, many other authors have made contributions to the literature on the cacodylates. Indeed, Peraldis in 1902 in the *Presse Médicale* drew attention to the fact that Gautier was by no means the first to advocate the therapeutic use of these preparations.

It is an American surgeon who is the first to draw attention to the parallel between cacodyle and "606" in the marked specific action displayed by both, based on his own experience. In the *Journal of the American Medical Association* of Sept. 24th, 1910, Dr. John B. Murphy of Chicago describes the results which he has obtained in the treatment of syphilis with the use of sodium cacodylate, which at first cause one to believe that the paper deals with the remarkable successes attendant on the use of Ehrlich's diamidodioxybenzol, so similar is the effect displayed by both drugs.

Dr. Murphy has been using sodium cacodylate for seven years to allay the pain of metastatic, osseous carcinomata, and also for the various other purposes for which arsenic is indicated. He states that one of its striking therapeutic effects is the rapid dissolution of the deposits in fibrinous pericarditis in children when administered in daily doses of one to three grains or even more. He then proceeds to give an account of his observations following the use of sodium cacodylate in the treatment of syphilis. The usual dose was one to two grains injected hypodermically into the muscles. The effect is remarkable: the spirochætæ disappear completely from the primary chancre in 48 hours, the induration is markedly reduced in 24, and it becomes a soft, clean ulcer in 72 hours. "From that time on it repairs with the same speed as an aseptic sore of mechanical origin would heal in the same tissue. In other words, the sodium cacodylate seems to destroy the specific microorganism (the spirochæta) which is keeping up the irritation." The microscopic examination in one case (illustrated by photographs) showed that the spirochætæ had disappeared within 48 hours from a chancre on the lip contracted from contact with a drinking cup, and following two injections of half a grain each into the pectoral muscle 24 hours apart, while only a clean soft ulcer without induration remained. Thirteen days after the initial treatment the ulcer had healed completely and had left no evidence of the disease. In all, ten injections of half a grain each were made and four injections of three-quarters of a grain. Dr. Murphy states that—

> The adenopathies, except those with suppurating central foci, disappear in four or five days. The mucous patches repair in from twenty-four to forty-eight hours, the advancing ulcers of the palate and posterior wall of the pharynx clear up and heal as healthy granulating wounds in from three to six days and the perforating ulcers of the palate repair in their margins, leaving the perforation in a healthy condition. ..... In a child nine months old with a papillary syphilide, a quarter-grain dose was administered into the pectoral muscle. The rash entirely disappeared in forty-eight hours.

As Dr. Murphy proposes to use the 25 doses of Ehrlich's "606" which he has received in control cases with sodium cacodylate, his results may be awaited with interest; and certainly his suggestion deserves attention to make further trials with a remedy as safe as sodium cacodylate. He suggests that the primary dose should be from two to four grains, and should not be repeated within three or four days. Over diamidodioxybenzol it presents the advantages that it is stable, and its solutions can be sterilised without fear of decomposition, while the injections are practically painless. On the other hand, it is not a proprietary preparation and its pharmacological action is well established.

Sodium cacodylate, $(CH_3)_2AsO_2Na+3H_2O$, is readily soluble in water and contains 46·8 per cent. of arsenium, equivalent to 61·8 per cent. of arsenious acid. As yet its mode of action in the organism has not been clearly explained. By some authors it is assumed that its action is due to its transformation into arsenious or arsenic acid, while others attribute a specific action to the cacodyle molecule, a view supported by the observation of Fraser, who found that no arsenic action followed the internal or subcutaneous administration of sodium cacodylate and that the preparation left the organism unchanged. Heffter, on the contrary, is of opinion that its effect is due to the liberation of arsenic, and found that traces of arsenious acid could be demonstrated in the urine, while certain organs, such as the liver, intestine, and walls of the stomach, have the property of reducing cacodylic acid. This would explain the odour of cacodyle oxide which appears on the internal administration of the cacodylates, but which is generally absent following its subcutaneous exhibition.

The innocuousness of the drug is demonstrated by the fact that there is no mention in the literature of any serious optic derangement or alarming symptoms consequent on its administration during the past 10 years. In view of the recent success in the treatment of syphilis with arsenic, it is of interest to recall to mind that Gautier did not attribute any specific action to arsenic medication, but believed its beneficial action in this affection to be due to its important property of improving the general condition. Oppenheim (*Klinisch-therapeutische Wochenschrift*, 1907, p. 1170) is one of the most recent authors who refer to the use of sodium cacodylate in syphilis, which he regards as preferable to atoxyl and amino-phenylarsenic acid by reason of its lesser toxicity. The preparation has hitherto met with little interest in Great Britain, and it is principally in France and in Italy that it is extensively used. It is now official in the pharmacopœias of France, Italy, and Switzerland.

I am, Sir, yours faithfully,

Darmstadt, Dec. 5th, 1910. GEORGE P. FORRESTER, F.C.S.

THE NATIONAL COUNCIL OF PUBLIC MORALS.

To the Editor of THE LANCET.

SIR,—May we presume upon the sympathy which you have shown towards the National Social Purity Crusade to announce that this organisation will in future be known as the National Council of Public Morals, a title which is more in keeping with the comprehensive educational character of the work, and which we hope will further commend it to the churches, schools, and press of the whole country, and that its offices, through the generosity of Sir W. P. Hartley, will be at Holborn Hall, W.C.

In making this announcement, permit us to add that His Majesty, in kindly accepting a copy of "The Nation's Morals," being the report of our Public Morals Conference held at Westminster last July, graciously says that he fully shares the sympathetic sentiments of His late Majesty King Edward VII. towards this crusade, and that there is no one more anxious than himself to see the state of things (which we deal with) changed for the better.

May we further add, with His Majesty's knowledge, his message to the Convocation of York—"The foundations of national glory are set in the homes of the people. They will only remain unshaken while the family life of our nation is strong, simple, and pure"—will be the motto of the National Council of Public Morals. They express in most felicitous terms the object of this movement, of which the Lord Bishop of Durham is President for 1911.

We remain, Sir, yours faithfully,

WILLIAM SINCLAIR,
Chairman.
F. B. MEYER,
Vice-Chairman.

National Council of Public Morals, Holborn Hall, W.C., Dec. 19th, 1910.

A POINT IN CHOLELITHIASIS.

To the Editor of THE LANCET.

SIR,—Three months ago, with the help of Dr. John Morton and Dr. R. Home Henderson, I operated on a gall-stone case. There was nothing out of the ordinary in the conditions present except the number of calculi found. There was one marble-sized, round, almost encapsuled stone, with 796 others, small, cuboid, facetted. A week after operation three small ones came from the wound, making in all 800. I looked up Mr. Mayo Robson's book on "Diseases of the Gall-bladder and Bile-ducts" (second edition, 1900), and found that he had taken 720 from one of his cases.

Can any of your readers furnish me with, or direct me

where to procure, details of cases with as large or larger numbers removed by operation?

I am, Sir, yours faithfully,

Glasgow, Dec. 14th, 1910. DUNCAN MACARTNEY.

A QUESTION UNDER THE WORKMEN'S COMPENSATION ACT.

To the Editor of THE LANCET.

SIR,—I give a note (certificate) to a man with a "beat knee" dated Dec. 1st. Certifying surgeon comes along when he pleases, not when asked, at least not as early as he could have come. He dates certificate of suspension Dec. 8th, the day he saw patient, but puts in the suspension certificate that patient has suffered since Dec. 1st. How do the owners pay compensation—from my date, Dec. 1st, or certifying surgeon's date, Dec. 8th?

I am, Sir, yours faithfully,

Dec. 14th, 1910. SIMPLEX.

*** The employers are liable to pay compensation from the date of disablement, which for the purposes of Section 8 of the Workmen's Compensation Act, 1906, "shall be such date as the certifying surgeon certifies as the date on which the disablement commenced" (Section 8, Subsection 4). This assumes the incapacity to be of more than two weeks' duration. We are not of the opinion that our correspondent has any cause of complaint against the certifying surgeon, as his letter seems to suggest, and we think he will find the certificate, which is not before us, is one of disablement not of suspension, following the form (Form 3) laid down by the Secretary of State, and rightly giving the date of the certifying surgeon's examination, as well as that which he has been able to fix as the date of disablement.—ED. L.

MALARIA IN ITALY IN 1909.

(FROM A CORRESPONDENT.)

THE "Società per gli Studi della Malaria" in its report for the year 1909 calls attention to observations in Algeria by the brothers Sergent and by Pölettini, Memmi, and Pozzilli, proving once more the existence of carriers of malaria. Persons were found who had malarial parasites, even parasites of the æstivo-autumnal variety, in their blood, without showing the slightest febrile reaction. These apparently healthy carriers, some of whom were children and some adults, are most dangerous from the epidemiological standpoint, forming reservoirs, as it were, very difficult of detection, from which the new epidemical torrent emerges. Add to these the chronic cases of latent infection and the links connecting one epidemic season with another become evident. No simple easy method of detecting such cases has yet been discovered.

Besides the ordinary pre-epidemic recrudescence of recidivous cases there has been observed a recidivity which is of a more prolonged type and may be called periodic, recurring in the years of epidemic recrudescence. It has not been possible to trace any relation between the number of anopheletes or between the meteorological conditions and the periodic recrudescences; rather it would seem that these are regulated by biological causes such as this periodic recidivity and by a loss of the immunity conferred by previous attacks. As regards prophylaxis, the report has again to lament a diminution in the quantity of State quinine consumed in the past financial year, 1909–10, to the extent of nearly 2000 kilogrammes upon that of 1908–09, which in its turn showed a diminution of 715 kilogrammes upon that of 1907–08. Associated with this diminished use of quinine there has been an increase of malaria in nearly all those provinces where such diminution has taken place. The following table gives the figures since 1902 (when the use of State quinine was begun) relating to the consumption of quinine and the mortality from malaria. The mortality for only the first half of 1909 is available. It shows a total diminution, however, of 949 deaths on that of the corresponding period of 1908.

Consumption of State quinine.		Mortality from malaria.	
Financial year.	Kilogrammes sold.	Year.	Total deaths.
—	—	1900	15,865
—	—	1901	13,558
1902–1903	2,242	1902	9,908
1903–1904	7,234	1903	8,513
1904–1905	14,071	1904	8,501
1905–1906	18,712	1905	7,838
1906–1907	20,723	1906	4,871
1907–1908	24,351	1907	4,160
1908–1909	23,635	1908	3,463
1909–1910	21,665	1909	—

Besides the fall in mortality there is a noticeable absence of the great periodic oscillations in the mortality curve which characterised it in the year preceding the date of State-supplied quinine. The fall is still more evident in the statistics of Latium, Southern Italy, and the islands where, before it was supplied gratuitously, quinine was beyond the reach of the greater part of the population. Further, whereas prior to 1902 the malaria mortality and the general mortality were subject to the same variations and fell at about the same rate, after that date the former made a precipitous descent, leaving the latter at the comparatively high level which it still maintains.

Unfortunately, the same cannot be said of the *morbidity* rate for malaria, which, in some regions especially, still remains very high, doubtless because of the neglect of the prophylactic as compared with the therapeutic use of quinine. An experiment carried out at Vigasio in 1909 strikingly confirms this explanation. All adults in that place who had been attacked during the previous season by malaria were carefully treated with quinine for the last 50 days of the pre-epidemic, as well as during the whole epidemic period of 1909, the rest of the population, with the exception of 132 children who also received prophylactic treatment, not taking any quinine as a preventive. An epidemic of primitive infections nevertheless broke out, affecting 17·3 per cent. of adults and only 12·7 per cent. of all children (who it is well known are the more susceptible), while not one of the 132 children prophylactically treated was attacked. The value of the prophylactic method was also abundantly shown in the "demonstration camps" organised both in Italy and abroad in connexion with the army, the schools, the mines, the country estates, and the agricultural population of the Agro Romano and Pontine Marshes, among all of whom only a very small fraction contracted malaria. The doses of quinine administered for the purpose of prophylaxis (amounting sometimes to 10 or 12 grains daily) have proved uniformly innocuous. In the case of children it is given in the form of chocolates of tannate of quinine in doses of 2½ grains and upwards daily, according to age, and far from harming them is found to act as an excellent tonic. When practicable the use of wire gauze has been continued, with the same good results as formerly. In such a country as Italy, with but limited means at its disposal, no attempt has been or can be made with any hope of success to attack malaria by the destruction of the anopheles.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool University: The Dutton Memorial Professorship of Tropical Entomology; the Lectureship in Operative Surgery.

IN 1905, it will be remembered, the late Dr. J. E. Dutton lost his life in the Congo from spirillum fever, a disease which he, together with the other members of the twelfth expedition of the School of Tropical Medicine, were investigating. He succumbed after a short illness. In view of the many great services that Dr. Dutton had rendered to the investigation of tropical medicine, although he died at the early age

of 28, the Liverpool School of Tropical Medicine set about collecting a sufficient sum of money to endow a professorship in the University of Liverpool in connexion with tropical medicine to commemorate the sacrifice of his life. The movement has now reached completion, and the school has been able to offer the University the sum of £10,000 for the establishment of a chair in tropical entomology, which has been gratefully accepted. This makes the second chair given to the University by the Liverpool School of Tropical Medicine, the first being the "Sir Alfred Jones chair in Tropical Medicine." The Liverpool School of Tropical Medicine, under the guidance of its new chairman (Mr. W. H. Lever), continues to receive valuable support on all sides, and has had this last term a record number of students.—Mr. Keith W. Monsarrat, the dean of the Faculty of Medicine, has been selected for the new lectureship of operative surgery in the University.

Liverpool Education Committee and Defective Vision in Children.

The education committee has adopted the following resolutions in regard to the testing of the eyesight of children attending the elementary schools who are reported by the school medical officers to have defective vision and whose parents are found to be unable to defray the cost:—

1. That every such child shall receive a voucher to be redeemed at the price of 3*s*. if signed by a registered medical practitioner recognised by the local education authority for this function.
2. That a list be prepared of such hospitals and registered medical practitioners as the sub-committee considers to be properly equipped for such work, and as have expressed their desire to undertake it.

These resolutions are open to serious objection in that refraction work, especially in the case of children, requires considerable training, so that the fee is quite inadequate to the time and skill demanded. Why should Liverpool offer less than the Liscard education authority, or the Bangor county council? Both are paying at the rate of 21*s*. per four cases dealt with, the work being done by surgeons of special equipment.

Dec. 19th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Trypanosomiasis and the Cinematograph.

THE latest meeting of the Bristol Medico-Chirurgical Society was marked by a departure from the ordinary course of events. The evening was devoted to a lecture on trypanosomiasis by Captain F. P. Mackie, I.M.S., an old Bristol student and a member of the Royal Society's Sleeping Sickness Commission. The meeting was held in the new chemical theatre of the University, by kind permission of Professor F. E. Francis, and there was a large attendance. The lecture was illustrated by microscopical specimens and by an admirable series of lantern slides; and it was followed by a remarkable cinematographic demonstration of trypanosomiasis experimentally induced in the rat, the films used being prepared and exhibited by Pathé Frères of London and Paris. Dr. M. Nierenstein, a member of the chemical staff of the University, whose work on atoxyl and allied bodies is well known, also spoke.

Long Fox Lecture.

On Dec. 15th the sixth Long Fox lecture was delivered to an interested audience in the medical library of the University of Bristol by Professor J. Michell Clarke, the Vice-Chancellor being in the chair. The subject chosen was Cerebro-spinal Syphilis. The lecturer's wide experience of neurology gave a personal note of authority to the discourse, which included remarks on the parasyphilitic processes, the gummatous and arterial lesions of the brain and cord, and on syphilitic affections of the meninges. A number of interesting lantern slides served to illustrate the lecture. The previous lecturers have been Dr. John Beddoe, F.R.S., Dr. R. Shingleton Smith, Dr. P. Watson Williams, Mr. J. Herbert Parsons, and Professor Edward Fawcett.

George Allen Norman, M.B. Oxon., L.R.C.P., L.R.C.S. Edin.

The funeral of Dr. G. A. Norman took place at Ipplepen, Devon, on Dec. 15th, in the presence of a large gathering. Dr. Norman, who received his medical education at St. George's Hospital and Oxford University, graduated M.B. of Oxford in 1870, after having qualified L.R.C.P. and L.R.C.S. of Edinburgh during the previous year. Dr. Norman in his younger days was a good athlete and a successful competitor at the United Hospitals' athletic sports in London. He was at one time surgeon to the Monmouth and County Hospital. Dr. Norman practised for many years in California and came to Ipplepen about seven years ago. He was very highly esteemed in Ipplepen and the district, and much regret is felt there at his death.

South Devon and East Cornwall Hospital, Plymouth.

As a result of the Hospital Sunday collections which took place at Plymouth on Oct. 23rd, the sum of £755 has been handed to the treasurer of the South Devon and East Cornwall Hospital.

The Falmouth (Cornwall) Board of Guardians and Tuberculosis.

At the meeting of the Falmouth board of guardians, held on Dec. 15th, a special committee reported in favour of urging the Local Government Board to make the notification of pulmonary tuberculosis compulsory in Cornwall, and suggested that the question of the establishment of a sanatorium for tuberculosis for the county should be pressed forward.

Dec. 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Honour for Scottish Universities.

THE King has been pleased to command that the three ancient Scottish Universities of St. Andrews, Glasgow, and Aberdeen shall be included amongst the representative bodies having the right of personal access to the Throne for the presentation of addresses. This honour has hitherto only been held by the General Assembly of the Church of Scotland, the corporation of the City of Edinburgh, and the University of Edinburgh, whose representatives are invariably received by the Sovereign when presenting addresses of loyalty.

Teachers' Recommendations re Inspection of Children.

The committee appointed by the Glasgow Local Association of the Educational Institute of Scotland with reference to the medical inspection of school children reports that the methods of conducting the inspection in Edinburgh, Renfrewshire, Dumbartonshire, and Stirlingshire, Glasgow, Govan, and other parts of Lanarkshire, have been carefully considered. These methods differ very considerably even in the same county, and accordingly the committee recommends that: (1) The ordinary work of the school should not be interfered with by excessive demands on the teachers' time; (2) the educational work of the teachers should not be brought into disrepute by requirements which may lead to conflicts with the parents; and (3) duties requiring medical skill, however simple, should not be imposed upon the teachers. The committee further suggests that teachers may reasonably be asked to (*a*) forward to the medical officer or local education authority the names and addresses of the children to be examined; (*b*) distribute, by means of the children, notices to the parents informing them of the date of the medical inspection; and (*c*) supply such particulars respecting each child to be examined as are contained in the ordinary school records—e.g., regarding regularity of attendance, &c. It is also suggested that teachers should not be required to (*a*) fill up and sign notices to the parents regarding the necessity of future advice or treatment; (*b*) measure and weigh children; (*c*) test children's eyesight, examine their teeth, or examine them for vaccination marks; (*d*) enter on school cards details respecting state of clothing, footgear, cleanliness, nutrition, speech, mental condition, work outside school hours, parent's occupation, size of house, &c.; (*e*) dress and undress the children during the inspection; (*f*) fill in doctor's observations in the cards as inspection proceeds; and (*g*) enter all details of cards in duplicate in a schedule or register.

Death of Dr. James Maxwell of Tobermory.

The death took place at Campbeltown last week of Dr. James Maxwell, who for many years was medical officer of Tobermory, which post he was obliged to resign a short time

ago owing to failing health. Dr. Maxwell was born in Glasgow and was educated in Campbeltown. He studied at the University of Glasgow and shortly afterwards was appointed medical officer of the parish of Tobermory. During his long residence there he took a deep and active interest in the affairs of the parish, being a member of the school board and an officer in the Argyll and Bute Artillery, and being also identified with other organisations. He was very popular in the Island of Mull and was held in the highest esteem in the circles in which he moved. Dr. Maxwell at the time of his death was 54 years of age and was unmarried.

Treatment of Consumption in Aberdeen.

On Dec. 14th, at a meeting of the public health committee of the Aberdeen town council it was agreed, on the recommendation of Dr. Matthew Hay, medical officer of health, to open one of the reconstructed and extended pavilions of the Aberdeen City Hospital for the treatment of pulmonary tuberculosis. This will be done as soon as the new heating arrangements are completed. In his report Dr. Hay states:—"According to the recognised standard of one bed per 1000 of population, the whole accommodation of the City Hospital, as recently extended, is scarcely more than is necessary to meet the requirements of ordinary zymotics, if they are to continue to be removed to the hospital in as liberal proportions as in the past; but owing to great fluctuations in their prevalence there are considerable stretches of time within which some of the wards stand unused. With this in view I suggested to the committee, when engaged in planning the additions, that one of the reconstructed and extended pavilions should be so arranged as to make it convenient and suitable for the treatment and care of cases of pulmonary tuberculosis or consumption. These arrangements are such that they will not interfere with the use of the pavilion at other times, for ordinary zymotic cases, when epidemics of the highly infectious and dangerous diseases demand it. ..... It is an educational gain that the treatment of the cases will be carried out in a hospital which is easy of access and is visited twice a week by large numbers of the relatives of patients. The tuberculosis wards will be a constant object-lesson. The pavilion, with its two main wards and four small wards, is capable of accommodating 32 to 36 adult patients, and there is no reason why a few cots should not be placed in each ward for the treatment of non-surgical cases of tuberculosis in children."

Hospital Accommodation at Aberfeldy.

Arising out of an inquiry by the Local Government Board as to the views of the burgh medical officer (Dr. J. Mackay) in regard to the hospital accommodation for infectious diseases in the burgh, the medical officer reported at a meeting of Aberfeldy town council on Dec. 12th, that in his opinion it would be more satisfactory if the burgh local authority erected a small hospital for its own use; but failing its doing this, the next best thing to do was to send the patients to Perth, and if the authority continued to adopt this course he suggested procuring an ambulance wagon for the burgh. The town clerk was instructed to make inquiries regarding the purchasing of a second-hand wagon.

Dec. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Fellows of the Royal College of Surgeons in Ireland.

A SPECIAL meeting of the Royal College of Surgeons was held recently on the requisition of a number of the Fellows. A resolution was adopted recommending the Council to limit the appointment of examiners to Fellows of the College. At present examiners must be Fellows or teachers in a recognised school of medicine. This resolution, if carried out by the council, will exclude several teachers in the schools from being appointed examiners.

The Chair of Midwifery in the School of Physic.

Last year when proceeding to elect to the chair of midwifery in the School of Physic, the Royal College of Physicians invited each candidate to state whether, if elected, he would resign the chair if he should become master of a maternity hospital. The candidates had no choice but to assent, and in consequence Dr. H. Jellett, who was elected, and has recently become Master of the Rotunda Hospital, has now resigned the chair of midwifery. A successor will be elected in March, and in the meantime Dr. Jellett has been invited to continue his course of lectures. The condition imposed by the College has roused some criticism.

Conference of Poor-law Guardians.

It was perhaps owing to interest being centred on the General Election that the attendance at the Conference on Poor-law Reform held recently at the Mansion House, Dublin, was very small. The conference was summoned by the Irish Workhouse Association, of which the Earl of Mayo is president, and all the boards of guardians in the country were invited to send delegates. As a matter of fact, out of some 150 boards only 11 were represented. Resolutions to the following effect were passed:—

That the county should be the area for which special institutions for the sick and aged should be maintained, and the cost should be paid out of the county and county borough rates.

That the duty of making suitable provision for the feeble-minded should be an imperial charge.

A motion approving of certain proposals in the report of the Vice-Regal Commission in preference to those of the Royal Commission fell to the ground, the numbers of those voting on each side being equal.

The Women's National Health Association.

The annual meeting of the Dublin branch of the Women's National Health Association was held last week in the Royal College of Physicians. The annual report stated that the branch had now completed three years of work. The branch employed two nurses to visit patients suffering from tuberculosis to advise as to precautions against infection, and gave help in other ways. The pasteurised milk depôt was selling between 35 and 40 gallons of milk a day, and 82 babies were at present being supplied with such milk. A babies' club was founded a year ago and was at present attended by about 20 mothers with their babies. They got instruction in sewing, cooking, and the care of children generally. Once a week the babies were medically examined and advice given to the mothers. Nurses also visited the babies at their homes. The branch was also organising a corps of visitors in connexion with the Early Notification of Births Act, which had been recently adopted by the corporation of Dublin. Steps were being taken to organise "tuberculosis classes" on the lines of those conducted by Dr. Pratt of Boston. Lady Aberdeen presided.

The Department of Agriculture and the North Dublin Sanitary Authority.

For some months past a prosecution has been pending against the Department of Agriculture by the North Dublin rural council as sanitary authority of the district in which the model farm of the Department is situated. It appears that in the farmyard a heap of manure is placed in closer proximity to the cowsheds than is allowed by the regulations of the rural district council, and after repeated warnings the council finally prosecuted the manager of the farm. The Department set up the defence that the manure was in its proper position, that it was not too close to the cowsheds, and that its removal to any other site would be impracticable. In fact, as a lesson in farm management to the country at large the manure was declared to be in the only suitable position. On a first hearing the bench of magistrates was equally divided, and the council then withdrew the prosecution.

Medal for the Countess of Aberdeen.

The Countess of Aberdeen has received the medal of the International Association for Medical Instruction, conferred in recognition of the campaign against tuberculosis in Ireland.

Dr. C. J. Clibborn, J.P.

Last week, in the City Hall, Belfast, Dr. C. J. Clibborn, late medical inspector of the Local Government Board, who has recently retired under the 65 years age limit, was presented by the dispensary medical officers of the Belfast area with a very handsome solid silver salver inscribed as follows:—

Presented to Cuthbert J. Clibborn, M.D., J.P., on his retirement from the position of Medical Inspector, Local Government Board, with the best wishes of the members of the Dispensary Medical Staff of Belfast Union, and in recognition of the marked ability, courtesy, and consideration which he invariably displayed in the discharge of the duties of his office; 12th December, 1910.

The autographs of the 17 members of the dispensary medical

staff surround the inscription, which occupies the centre of the salver. At the meeting in the City Hall Mr. S. B. Coates presided, and complimentary speeches were delivered by the chairman, Mr. C. J. Milligan, Mr. H. D. Osborne, Dr. Robert Thomson, J.P. (chairman of the Belfast public health committee), Mr. H. W. Bailie (medical officer of health), and Mr. R. Meyer (town clerk of Belfast). Dr. Clibborn made a very feeling reply of thanks.

The Forster Green Hospital, Belfast.

At the opening meeting of the Belfast division of the British Medical Association for this session, held in the Medical Institute, Belfast, on Dec. 15th, the chairman, Dr. John Simpson, in his introductory address, gave a most interesting account of the origin and evolution of "the Forster Green Hospital for Consumption." A discussion followed on Tuberculosis, each speaker being limited to seven minutes. The following took part:—Professor T. Sinclair, Tubercle of the Serous Membranes; Sir John Byers, Tubercle in Relation to Pregnancy; Dr. W. Calwell, Susceptibility from a Clinical Standpoint; Dr. H. L. McKisack, Value of Physical Signs in the Estimation of a Lesion; Mr. A. B. Mitchell, Tubercle of the Stomach and Duodenum; Dr. Thomas Houston, Laboratory Diagnosis and Treatment; Dr. C. E. Shaw, Tubercle of the Larynx and Eye; and Mr. A. Fullerton, Tubercle of the Kidney. The chairman, in bringing the discussion to a close, spoke of the great value and interest of the work brought forward at that meeting.

Action of Ultra-violet Rays on Tuberculin and on Antituberculous Serums.

AT a recent meeting of the Biological Society M. Jousset said that the experiments of M. and Mme. V. Henry and of M. Baroni seemed to show that Koch's tuberculin was destroyed by prolonged exposure to ultra-violet rays. In reality the tuberculin was only rendered inactive; it lost its toxic properties, but retained the whole of its specific precipitating power with respect to the blood serum of immunised animals. This fact added another to the already existing proofs of the extraordinary power of tuberculin to resist destruction. On the other hand, antituberculous serums soon underwent important modifications under the influence of the same rays; the specific precipitating power disappeared in a few minutes, and in the course of some hours the serum became viscid and formed a jelly. This was, in the opinion of M. Henry, a change common to many colloid bodies. Moreover, when the irradiation was pushed a little further serum which had been rendered colourless by dilution assumed a dirty yellow tinge similar to that of serums which had been left in diffused daylight for many years. In this case it behaved as if it contained a true chromogenic substance.

Action for Damages against a Surgeon.

In these columns on Dec. 10th, p. 1731, I mentioned that Dr. Bazy had been ordered to pay 5000 francs damages to a female patient in whose abdomen he had inadvertently left two compresses measuring 1 metre in length and 30 centimetres in width. He immediately appealed against this decision, and has also brought the case before the Society of Hospital Surgeons, asking the society to consider whether it was possible—even on the hypothesis that the compresses had been forgotten in a cyst—for the cyst to become ulcerated, to set up ulceration of the intestine, and to allow the escape of two compresses of the dimensions above stated without ever producing any symptom of fæcal fistula. Such a sequence of events would imply the immediate formation of a permanent cicatrix, but of this the experts had not been able to find any trace. In the next place Dr. Bazy told the society that this decision would form a precedent which, by giving opportunities for blackmail, would threaten the independence of the profession every day, and that it would enable unscrupulous persons to live at the expense of surgeons. He also suggested that the society should take the requisite measures, and if necessary should enter into communication with the Government, so that surgeons might not be harassed in the practice of their profession. In the result the society decided to appoint a committee to consider the question.

The Age for Retiring from Practice.

Last January a collision occurred between a motor vehicle and the carriage of Dr. Cheurlot, who was seriously injured and for nine months unable to visit patients. The chauffeur of the motor vehicle was fined 50 francs, and the matter afterwards came before a court of law for the purpose of deciding on the damages to be paid to Dr. Cheurlot. He claimed 220,000 francs, of which 10,000 francs were assigned for medical attendance and medicine, 60,000 francs for the lost time during which he had not seen patients, and 150,000 francs for prospective diminution of his practice on account of his confinement to the house and his present condition of weakness which did not allow him to work as he had formerly done. The court awarded him only 60,000 francs, at the same time remarking that when medical men reached Dr. Cheurlot's age of 68 years, after a long, honourable, and prosperous career, most of them were desirous of taking their well-earned rest and of being less burdened with the fatigues of practice.

The Prix Lannelongue.

The Surgical Society has just awarded the Prix Lannelongue to Sir Victor Horsley of London. This prize is given every fifth year, without distinction of nationality, to the surgeon who has during the previous ten years accomplished the best surgical work.

A New Method of Extension in Fractures of the Limbs.

At a meeting of the Society of Paris Surgeons M. Dupuy de Fenelle showed a new apparatus for maintaining extension of the limbs by Steinmann's method. It was provided with two long points for deep insertion into the lower extremity of the bone for which lengthening was required. These two points slid on a bar and could be brought nearer to one another by means of two screws, an arrangement which allowed them to be introduced by degrees without using force; two rings carried the cord by which traction was made. This apparatus enabled continuous traction to be kept up in fractures complicated with much comminution. In more than 50 cases treated in foreign countries it has been employed for the correction of shortenings of a limb amounting to 8 or 10 centimetres. The use of this apparatus was indicated whenever other methods had failed. It was more simple than a cutting operation and could be applied under local anæsthesia.

Dr. Doyen's Dispensary.

At the conclusion of a course of lectures on immunity which he has delivered at the Hôtel des Sociétés Savantes Dr. Doyen announced that he is opening a free dispensary where all patients provided with cards from the *bureau de bienfaisance* of the city of Paris will receive treatment for tuberculosis and other infectious diseases, whether acute or chronic. Dr. Doyen has already been treating patients by his immunisation method for the last three years, and during that time 30,000 tubes of liquids for injection have been supplied to 900 medical men in the country districts and abroad who have treated 1020 patients, many of them being in an advanced stage of their illness. The general statistics show the following results for pulmonary tuberculosis in each of the three stages: in the first stage, 60 per cent. of recoveries in three months and 35 per cent. of cases improved; in the second stage, 25 per cent. of recoveries in six months and 60 per cent. of cases improved; and in the third stage, 8 per cent. of recoveries in six months and 60 per cent. of cases improved.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Franz König.

Professor Franz König, formerly professor of surgery at the Universities of Göttingen and Berlin, died in Berlin on Dec. 12th at the advanced age of 78 years. His last illness was of only a few days' duration, the cause of death being pneumonia. He became, after the death of Professor von Esmarch, the oldest of the German surgeons and one of the few who had been professors of surgery before the era inaugurated by Lister. He was born in 1832 at Rotenburg-on-Fulda, where his father held the appointment of medical attendant to the landgrave. He took

the degree of M.D. in 1855 at the University of Marburg and passed the State examination in the following year. After having held for a short time an assistantship at the medical clinic of that University, he went to Berlin for post-graduate study under the celebrated Professor Langenberg and the ophthalmologist, Professor Graefe, and in 1858 he became an assistant to Dr. Roser, professor of surgery in the University of Marburg. In 1860 he settled in Hanau as a medical officer of health, and at the same time became a surgeon to the hospital of that city. There he published a good many observations on clinical cases and on new operative methods, especially on wounds of the lungs, on stenosis of the rectum, and on tracheotomy for croup. His greater work, however, was on resection of the joints, which made him so well known in the surgical world that he was invited to become ordinary professor of surgery at the University of Rostock, where he remained till 1875, with only a short interruption, caused by the Franco-German war. In 1875 he was appointed ordinary professor of surgery at Göttingen, and resided there until 1895, when he was invited to succeed the late Professor Bardeleben at the University of Berlin. In 1904 he resigned his professorship and retired to Jena, afterwards returning to Berlin. Notwithstanding his great age he continued to attend the meetings of medical societies and to take part in the discussions. Professor König was the author of a large text-book of surgery, which was first published in 1876. This standard work, which was always kept up to date by the author, and of which the eighth edition has recently appeared, has been translated into several languages and has made the name of Professor König widely known.

Ehrlich's New Remedy "No. 606" in Internal Diseases.

At a recent meeting of the Verein für Innere Medicin Professor Michaelis read a paper on the administration and effects of Professor Ehrlich's new remedy "No. 606" in internal diseases. He said that he preferred to give it by intravenous injections and had employed this method in 35 cases. The injection was usually followed by slight shivering, and sometimes there was a rise of the patient's temperature for one or two days. This mode of administration was absolutely painless, whilst intramuscular injection caused severe pain and great infiltration. When given intravenously this substance was absorbed at once and was also eliminated rather quickly—namely, in from three to four days—but after intramuscular injection it remained a long time in the body. A toxic action did not occur in healthy persons, but patients weakened by an illness of long duration were liable to have their symptoms aggravated under the treatment; disorders of metabolism, heart disease, and acute Bright's disease were therefore contra-indications as regards this substance. A syphilitic patient could not be completely freed from the disease by a single injection; the injection must be repeated, and this must be done even although the Wassermann reaction has proved negative after the preceding injection, because it will very likely become positive in the course of a short time. An intermittent treatment must be adopted on the same principle as in treatment by mercury. Ehrlich's remedy has proved itself superior to mercury and iodine because of its quicker action; this was especially important in cases of gumma of the trachea, the liver, and the kidneys, in which it was essential that the threatening symptoms should disappear at once, leaving the systematic treatment of the patient for subsequent consideration. No benefit could be expected from the administration of "606" in cirrhosis of the liver, aneurysm, and amyloid degeneration, but it might be tried in syphilitic arterio-sclerosis. Cases of syphilitic periostitis and arthritis which had resisted treatment with mercury and iodine, often became better after an injection of "606," and the severe nocturnal pains might disappear. With regard to syphilitic affections of the central nervous system, Professor Michaelis stated that syphilis of the brain improved rapidly in certain cases; the vomiting stopped and the gait became less jerky. It was advisable to administer first a comparatively small dose to such patients, and to repeat it in from four to six weeks. He had treated 18 cases of tabes, the result being that the lancinating pains and the ataxy were frequently relieved for a period varying from two to four months, but reappeared afterwards: perhaps a second injection after that time would again be efficacious. In general paralysis he had seen one case in which there was a prompt remission persisting for three months, and after another injection the symptoms were again improved. In the discussion Professor Oppenheim pointed out that "606" was undoubtedly efficacious in syphilitic affections of the cerebro-spinal system, but not more so than mercury and iodine. In tabes the patient's general state sometimes became better and the pains diminished, but he had also observed an aggravation of the symptoms.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Improvement of Hygienic Conditions in Hungary.

THE cholera epidemic of this year has taught our Government a very useful lesson by showing that we were quite unprepared to deal with a serious epidemic, if such a one had occurred. Fortunately, however, the cases were mild enough not to claim too many lives. It is to be regretted that the bulk of our population pays little attention to the laws of hygiene. The young people learn elementary hygiene in the intermediate schools, and consequently believe in the infectious or contagious nature of some diseases, but the older men, and especially the women, cannot be persuaded of the necessity for disinfection. In some parts of the country the sanitary officials are regarded with so much disfavour that in a Hungarian village the medical officer, while engaged in disinfection, has even had to carry a loaded pistol in his hand. The National Public Health Committee has given instructions for the delivery of popular lectures on infectious diseases, their spread and their prevention, and on the advantages of disinfection. These lectures will be continued throughout the winter, because it is then that the rural population is most likely to have leisure for attendance at them. The ignorance of the peasantry with regard to these matters may be imagined from a description given by a village medical officer, who stated that public addresses on the methods of recognising and preventing cholera were delivered by him in all the villages throughout his district. Some of these villages were inhabited chiefly by Roumanians, of whom not less than 97 per cent. were quite illiterate. In such places the local magistrate, the clergyman, and perhaps one or two other persons presented themselves and laughed at him for advising them to wash their hands before meals, to wash their mouths, and to ventilate and whitewash their rooms. He, however, had a better reception in Hungarian or Schwabisch (German) villages, where his discourses were attended by a fairly large number of peasants, who were capable even of discussing some questions relating to public health. The report of this village medical officer led to the asking of a question in the Parliament, where the Minister of Instruction gave a conciliatory answer, saying that he would increase the number of elementary schools by about 100 per cent., and that he would enforce the regulations making school attendance compulsory. Should this promise be fulfilled the Roumanian villagers who have made their homes in Hungary will in course of time learn that they erred in drawing their knives and threatening to murder the medical officers if children suffering from scarlet fever were conveyed to an isolation hospital. A distinct advantage resulting from the cholera outbreak is that the towns and villages will be provided with good drinking water. In the Government Budget for next year several hundred thousand kronen are allotted for boring artesian wells in villages. Along the Danube hundreds of villages use river water for drinking purposes, and will consequently, in the event of an epidemic, be in danger of infection. The position of the village medical officers will also undergo considerable alteration in consequence of the cholera. Along the banks of the Danube the epidemic attacked many villages, where there had been no medical officers for a long time—in some places not even for many years. This is due to the very low salary given by the villages. The people expect that a man who has studied medicine for several years and been put to great expense before getting his diploma will settle in a village for the ridiculously small sum of 1000 kronen (£40) a year. Dr. Naday, writing in a recent issue of the *Orrosok Lapja*, says that more than 700 village medical officerships are vacant, and that in the event of a serious epidemic breaking out there would not only be great loss of life, but more money would be wasted than the payment of all the village medical officers for a decade would amount to. Dr. Naday's open letter was read by the authorities concerned, and a

response soon came in the form of a statement by the Minister of Internal Affairs to the effect that in the near future the medical officers in all the villages will have not only a uniform salary paid by the State, but also a fair pension. The minimum payment made by the State will be 2400 kronen (£100), rising by £20 every five years, and besides this fixed payment the villages will have to contribute in proportion to the number of their inhabitants. As an example of the popular feeling on this question, it may be mentioned that some comparatively wealthy villagers complained recently in a newspaper that they could not get rid of their medical officer, who was 83 years of age, and naturally incapacitated for work. They did not ask the county council to pension off this old practitioner, they merely asked the council to relieve them from continuing to pay his salary.

Tolstoy's Physician.

In their obituary notices of the distinguished Russian writer Tolstoy, the newspapers have mentioned, with regard to his enthusiastic adherent, Dr. Dusan Makoviczky, little more than that he was Tolstoy's family medical attendant and private secretary. In the issue of the *Journal of the Hungarian Medical Association* for Dec. 1st, 1910, Dr. Alexander Androvich, a personal friend and schoolfellow of Dr. Makoviczky (who, by-the-by, is a Hungarian by birth), gives some interesting details of his career as follows:—"Dr. Makoviczky practised in the 'nineties' at Zsolna in Upper Hungary, being then from 28 to 30 years of age. He was of middle size and slender build, with fair hair and beard, and blue eyes. He seemed to be a blend of the Slav and German type. Under an apparently morose exterior there dwelt in him a very mild and noble soul. He was spoken of in Zsolna as the 'curious eccentric.' He did not ask for fees either from rich or from poor, and it was only in exceptional cases that he could be induced to accept a modest payment. He gave the poor patients money, food, and medicines, as, in fact, he could afford to do, because his father was a very rich man, whose wealth was derived from cheese-making in Lipto, also in Upper Hungary. Dr. Makoviczky was highly educated. When only 25 years of age he was invited to become the first assistant at the surgical clinic at Innsbruck, but he declined the offer. He could give no reason why he refused this advantageous position; it seems that it was caprice. During the few years of his stay in Zsolna premonitory signs of his enthusiastic admiration for Tolstoy could be noticed. At this time he began to write in the Slav language pamphlets, the tendency of which was to combine scientific and idealistic Socialism; in a short time he began to approach the so-called 'Tolstoyism.' On account of his pamphlets he was prosecuted on a charge of Panslavism, but was acquitted after giving a satisfactory explanation of his views. He suddenly left Zsolna, and I did not hear anything about him until 1903, when Tolstoy's health was failing and the newspapers mentioned the name of Dr. Makoviczky as his medical adviser and intimate friend. No reference, however, was made to his Hungarian origin, and this fact was not known in Russia either, until a Hungarian reporter intending to interview Tolstoy was, to his surprise, addressed in Hungarian by the secretary. Dr. Makoviczky lived with Tolstoy for about seven or eight years." In conclusion, Dr. Androvich expressed his conviction that Tolstoy would never have a more enthusiastic admirer than Dr. Makoviczky has been.

Dec. 19th.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The council have received the following sums towards the repayment of the building debt: The Goldsmiths' Company, £100; the Mercers' Company, £52 10*s.*; Miss S. A. Turle, £200; F. C. N., £52 10*s.*; the late Mrs. Isabel Thorne, £50; Dr. May Thorne, £50; F. C. T., £50; Sir Charles Burt, £10 10*s.*; collected by Mrs. Starling, £74 1*s.*; and smaller sums amounting to £10 10*s.* The council has appointed Miss N. Laycock, B.Sc., to be demonstrator in biology, and Miss I. Pendlebury, B.Sc., to be demonstrator in physics for 1910–11. The St. Dunstan's Exhibition of £60 a year for three years has been awarded to Miss Lilian A. Clark of the City of London Girls' School, and the School Scholarship of £30 to Miss C. I. Fox of the Mount School, York, Miss K. Lloyd of the Welsh Girls' School, Ashford, being named *proxime accessit*.

Obituary.

WILLIAM HENRY CHARLES STAVELEY, F.R.C.S. ENG., L.R.C.P. LOND.

WE record with regret the untimely death of William Henry Charles Staveley, at 24, Sloane-gardens, Chelsea, in his forty-eighth year. He was born in London in 1863, the son of the late T. G. Staveley of the Foreign Office, was educated at Tonbridge School, and in 1881 joined the medical school of St. Thomas's Hospital. In 1886 he became M.R.C.S. Eng., L.R.C.P. Lond., and immediately obtained a series of house appointments, including that of house surgeon, a post which he filled with unusual distinction, earning the good opinion of all his seniors for ability and devotion to his work, while he obtained, what are not infrequently more elusive, the confidence of the patients and the esteem of the dressers and others who worked under him. Indeed, few St. Thomas's men won and retained so wide a circle of personal friends; none will be more widely missed or deeply regretted in this respect. His hospital career foreshadowed the success which awaited him in private practice, for he inspired in those who had the good fortune to become his patients similar confidence and regard.

Staveley took the Fellowship of the Royal College of Surgeons of England in 1890, and on leaving St. Thomas's Hospital was appointed resident clinical assistant at Bethlem Royal Hospital. He afterwards spent many months as resident medical officer at the Victoria Hospital for Children, where he did valuable work in connexion with intubation of the larynx, while with regard to the operation for adenoids, which was then in its infancy, he may be regarded as a pioneer. On leaving the Victoria Hospital he began general practice in the West End and established himself in South Eaton-place, afterwards removing to Sloane-gardens. It was not long before his sterling professional qualities and charming personality won for him a practice which was only limited by the exigencies of time and distance. To his patients he was all that a medical man can hope to be. Always hopeful and kindly, and gay on occasions, he was full of practical sympathy, generally knowing by intuition the best course to take, and always taking it steadily, clearly, and simply. Staveley had no pretensions, he never posed; but he knew his work, and how well he did it is shown by the trust which he inspired, by the general grief evoked by his early death, and by the fact that his brother practitioners believed in him implicitly and never envied him his success. He was an ideal general practitioner, and there can scarcely be higher praise for any member of modern society when we remember what is really signified by the phrase.

Staveley's health began to fail him of late years, tuberculous affection of the lungs compelling him on occasions to give up practice entirely, while it was difficult for him to work at the high pressure to which he had been accustomed. He went bravely on, cheery and undaunted by the illness which came upon him; a fine example of courage, ever ready with help and sympathy for those who wanted him, though his need was often greater than theirs. Like most men in busy general practice, he had little time for literary work, but he published several interesting papers in our columns and elsewhere, and in his early days edited, or rather re-wrote, "Gardner's Household Medicine." Away from his work he was a lover of country life and sport of many kinds, was a splendid swimmer, and an enthusiastic fisherman on sea and river. He attained European celebrity as a fencer, and in the most important competitions with foil or épée was always selected as a judge. He himself fought for England in more than one international competition. At the International Tournament at the Crystal Palace in 1904 he was chosen by all the foreign competitors to preside over the jury in the final pool for the International Épée Championship. He was entrusted in 1908 with the organisation of the foils display in connexion with the Olympic Games in London and the selection of the foil fencers who represented this country on that occasion. These important duties he discharged with complete success, his judgment and his absolute fairness remaining unquestioned.

We offer our sympathies to Mr. Staveley's family and many friends upon his untimely death, which followed upon an illness of terrible suddenness, acute septicæmic symptoms supervening on a small carbuncle. Doubtless his long-standing weakness had sapped his powers of resistance.

DR. H. HUCHARD.

FRENCH medical science has sustained a serious loss by the death of Dr. H. Huchard, who passed away on Dec. 11th at his residence at Clamart. He was born in 1844 at Auxon in the Aube. After being admitted *interne des hôpitaux* in the usual course, he graduated as doctor of medicine in 1875, became hospital physician in 1878, and in 1883 published jointly with Axenfeld a "Treatise on Nervous Diseases." He had, however, already devoted himself to the study of diseases of the heart and blood-vessels, and in 1884 he published a work on "Angina Pectoris," for which he was awarded the Prix Godard. He was from this time forth busily engaged at the Hôpital Necker, where he had a large following of students, but he nevertheless published numerous memoirs on various diseases of the heart and blood-vessels and on associated conditions. Most of these productions were incorporated in his "Clinical Treatise on Diseases of the Heart and Blood-vessels," which appeared in 1893, and for which he was awarded successively the Prix Montyon and the Prix Chateauvillard. In 1900 and 1906 he published two other volumes on clinical therapeutics, entitled "Medical Consultations," his other published works including "Treatment of Diseases of the Circulatory Apparatus," "Clinical Therapeutics," "New Medical Consultations," "Treatment of Diseases of the Heart," "Clinical Treatment" (written in conjunction with Dr. Fiessinger), and "Therapeutic Applications of Twenty Medicines." When arrangements were being made for the visit of the French medical men to London in 1904 he was one of its most zealous promoters. The high esteem in which he held his English professional brethren was well known, and he was fond of making jocular references to the *entente cardiaque et cordiale*. Dr. Huchard was a member of the French Academy of Medicine, an officer of the Legion of Honour, and one of the best-known French specialists on diseases of the heart. He founded and conducted the *Journal des Praticiens*, a widely read and highly appreciated periodical dealing with practical medicine. The announcement of his death evoked many expressions of sympathy and regret; he was very popular with his pupils and also with the general body of students, who had in him on all occasions a zealous defender of their rights.

Our Paris correspondent writes: "Before Huchard's discoveries the attention of medical men had been directed almost entirely to lesions of the cardiac orifices—lesions which were no more than residual conditions almost always inaccessible to treatment. To him belongs the merit of showing that many cases of heart disease are due to a functional disorder of the circulation which he called arterial hypertension and to arterio-sclerosis, of which this hypertension is only the first stage. Huchard fully recognised the importance of the conditions on which arterial hypertension depended, and showed that it might be reduced by the removal of these conditions, which are frequently amenable to treatment by hygienic measures and dieting. As he did not occupy any official chair in the Faculty of Medicine, it is the more to his credit that he was able to attract to his lecture room in the Hôpital Necker crowded audiences such as are not always to be seen in the great amphitheatre of the school. He was a master of the art of throwing light on the most difficult problems. In 1908, when he had reached the age limit for hospital physicians, he founded the clinic for diseases of the heart, where a great many medical men of all countries came for instruction, the clinical material being very large; since last June, however, he was unable to attend personally on account of ill-health. He was for 15 years the foremost consultant physician in France."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Adolf Freiherr von La Valette St. George, formerly professor of anatomy in the University of Bonn, at the age of 79. He was a man of great general and scientific attainments, and with Waldeyer and O. Hertwig edited the *Archiv für Microskopische Anatomie*.—Dr. Frank Newell Lewis, professor of ophthalmology in the New York Post-Graduate School of Medicine.—Dr. Nathaniel Pendleton Dandridge, formerly professor of surgery in the Miami Medical College, Cincinnati.—Dr. F. Suter, a Swiss surgeon who had only a short time ago commenced his duties as professor of surgery in the University of Lima, Peru, suddenly; his age was 37.—Dr. Hieronymus Laub, who was for many years the Director-General of the Danish Army Medical Service, aged 72.—Dr. M. von Cube, who belonged to Livonia, and practised for many years in St. Petersburg, but for a long time past has been one of the best known physicians in Mentone. His age was 79.—Dr. H. Huchard, the eminent Paris physician.—Dr. Labrousse, a French senator.

Medical News.

UNIVERSITY OF OXFORD.—In the recent examination for the degree of Bachelor of Medicine the following candidates were approved:—

FIRST B.M. EXAMINATION.

Organic Chemistry.—W. G. V. Blogg, K. G. Bowes, L. R. Broster, L. G. Brown, W. H. Butcher, J. B. Cavenagh, R. W. J. A. Cushing, J. F. Haynes, R. J. Inman, O. G. Parry-Jones, P. P. Reitlinger, S. W. F. Underhill, H. St. H. Vertue, and D. M. P. Whitcombe.
Human Anatomy and Physiology.—A. C. Ballance, C. H. Carlton, J. C. Davies, A. W. Dennis, C. H. L. Harper, A. L. Pearce-Gould, T. O. Thompson, and T. A. Townsend.

SECOND M.B. EXAMINATION.

Materia Medica and Pharmacology.—H. T. Evans, R. A. Fawcus, D. P. McDonald, W. R. Reynell, and R. C. Wingfield.
Pathology.—H. C. Bazett, W. H. Bleaden, N. G. Chavasse, P. L. Gibson, E. G. Martin, G. E. Neligan, and W. J. Pearson.
Forensic Medicine and Public Health.—A. R. Chavasse, W. A. Cooke, G. E. Downs, H. J. B. Fry, A. D. Gardner, P. L. Gibson, G. W. Johnson, G. E. Neligan, E. O'Connor, E. L. Pearce-Gould, J. F. Penson, and R. C. Wingfield.
Medicine, Surgery, and Midwifery.—R. F. B. Bowes, A. W. Donaldson, G. E. Downs, G. W. Johnson, E. P. Poulton, A. S. Roe, and R. C. Wingfield.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful:—

THIRD M.B. EXAMINATION.

General Pathology and Morbid Anatomy.—F. S. Beadle, *R. B. Berry, *A. G. Bryce, G. C. Dixon, Geoffrey Fildes, W. H. Kauntze, J. A. Lees, *P. H. Midgley, *T. H. Oliver, *S. B. Radley, L. W. Sparrow, C. F. White, *A. G. Wilkinson, and H. D. Willis.
* Distinction in Pathology.

SECOND M.B. AND CH.B.

Alan Barrett, F. A. Bearn, J. G. Bennett, E. S. Brentnall, F. S. Charnock, H. F. Hutchinson, Harold Kempsey, Eugene Leahy, W. L. Nicholson, T. P. Robertson, H. A. Sandiford, Cornelius Thompson, F. K. Tomlinson, C. H. Whittall, H. W. F. Williams, and G. W. Wood.
Anatomy.—L. B. Baird, F. L. Newton, and Ernest Talbot.
Physiology.—Harman Taylor.

THIRD B.D.S. EXAMINATION.

T. A. B. Corless.

DIPLOMA IN DENTISTRY (THIRD EXAMINATION).

H. D. Firth, Arnold Gibson, C. S. Harding, Harry Lyth, W. J. Piper, C. H. Plummer, Thomas Rothwell, and A. B. Tough.
Anatomy and Physiology.—D. M. Lawrie.
Dental Anatomy and Histology.—S. G. Ross.

UNIVERSITY OF LIVERPOOL.—At the examination for the Diploma in Tropical Medicine held recently the following candidates were successful:—

E. Brabazon, L. Castellino, J. A. Caulcrick, W. E. Haigh, H. F. Hamilton, W. St. M. Hefferman, A. Hipwell, J. Homer, W. M. Houston, D. P. Johnstone, A. G. Macdonald, C. C. Murison, P. D. Oakley, I. C. Pratt, E. L. Sieger, P. J. de Sousa, and J. H. Waterhouse.

FOREIGN UNIVERSITY INTELLIGENCE.—*Algiers:* Dr. Poujol, Professor *agrégé* in Montpellier, has been appointed Professor of Pathological Anatomy and Histology in succession to Dr. Weber.—*Atlanta (College of Physicians and Surgeons):* Dr. Justin F. Grant has been appointed Professor of Embryology and Histology; and Dr. W. W. Funk, of Philadelphia, Adjunct Professor of Bacteriology.—*Buffalo:* Dr. E. A. Bowerman has been appointed Lecturer on Hygiene.—*Catania:* Dr. Giovanni Alonzo has been recognised as *privat-docent* of Pathological Histology.—*Genoa:* Dr. Giovanni Romanelli has been recognised as *privat-docent* of Internal Pathology and Dr. Mari Vittorio Maragliano as *privat-docent* of Physical Therapeutics.—*Halle:* Dr. Theodor Heynemann has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Harvard:* Dr. Harvey Cushing, of Johns Hopkins University, has been appointed to the chair of Surgery.—*Marburg:* Dr. W. Zangemeister, of Königsberg, has been appointed to the Chair of Midwifery and Gynæcology

in succession to Dr. Stöckel.—*Naples:* Dr. Giuseppe Giordano has been recognised as *privat-docent* of Topographical Anatomy and Operations: and Dr. Raffaele D'Alise as *privat-docent* of Odontology.—*Parma:* Dr. Luigi Carozzi has been recognised as *privat-docent* of Trade Diseases.—*Philadelphia (University of Pennsylvania):* Dr. Richard M. Pearce, Professor in the University and Bellevue Hospital Medical College of New York, has been appointed Professor of Pathological Anatomy and Experimental Medicine. Dr. A. E. Taylor, Professor in San Francisco, has been appointed Professor of Physiological Chemistry.—*Toulouse:* Dr. Ribaut, Professor *agrégé*, has been promoted to the chair of Pharmacy.—*Yale:* Dr. Yandell Henderson has been appointed Professor of Physiology.—*Zürich:* Dr. F. Sauerbruch, of Marburg, has been appointed to the Chair of Clinical Surgery in succession to Dr. Krönlein.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Joseph H. Houldsworth of Glasgow, the London Homœopathic Hospital will receive £5000, while the Glasgow Royal Infirmary, the Western Infirmary, Glasgow, the Victoria Infirmary, Glasgow, the Royal Glasgow Asylum for the Blind, the Broomhill Home for Incurables, the Royal Hospital for Sick Children, Glasgow, and the Ayr County Hospital will each receive £1000.—The late Mrs. E. A. Freeman has, among other charitable bequests, left £1000 to the Halifax Infirmary, £1000 to the Royal Albert Idiot Asylum, Lancaster; and £500 to the Royal Bath Hospital, Harrogate.—By the will of Mr. Frederick Bloomenthal, some £30,000 have been left for charitable purposes, and the following institutions will receive about one-sixteenth of that sum: London Hospital, Guy's Hospital, St. Bartholomew's Hospital, St. Thomas's Hospital, St. George's Hospital, Westminster Hospital, Charing Cross Hospital, Royal Free Hospital, Gray's Inn-road, the Cancer Hospital, and Brompton Hospital for Consumption.—Sir Henry Harben has sent to St. Mary's Hospital, Paddington, a further donation of £1000 in memory of the late Mr. H. A. Harben; and to St. Bartholomew's Hospital £500 for the general funds of the hospital, and £500 for the Nurses' Home Rebuilding Fund.—The late Mr. H. Silver, the *Punch* artist, among other bequests, made the following: £50,000 to the Royal Free Hospital, Gray's Inn-road; £25,000 to the Royal Victoria Hospital for Children, Chelsea; £25,000 to the Hospital for Children, Great Ormond-street; and £2000 to the West London Workshops for the Blind.—Under the will of the late Miss Isabella L. Boustred the Seamen's Hospital Society, Greenwich, will receive £1000, the Royal Hospital for Incurables and the Hospital for Sick Children, Great Ormond-street, £200 each.

METROPOLITAN HOSPITAL SUNDAY FUND.—The annual meeting of the constituents of the Metropolitan Hospital Sunday Fund was held at the Mansion House under the presidency of the Lord Mayor on Dec. 16th. Sir John Bell, in moving the adoption of the report (already summarised in THE LANCET, Dec. 10th, p. 1725), said although the total of the Fund was less than last year, that was mostly accounted for by the fact that no legacies had been received. The Rev. P. Clementi-Smith seconded the resolution. The Rev. D. S. Lewis asked for information with regard to the grant to St. George's Hospital. Sir William Church, chairman of the Distribution Committee, said that the award was made upon exactly the same terms and bases as those to all the other hospitals in accordance with the sum expended on maintenance of its patients. The smaller grant to the hospital last year was due to an exceptionally large number of legacies, which placed its accounts on the right side of the ledger. The Rev. D. S. Lewis then moved as an amendment that the report be adopted, with the exception of the grant of £1545 to St. George's Hospital, which should be referred back to the Distribution Committee for further consideration, and that the committee should report to the general meeting called for the purpose, after King Edward's Hospital Fund had publicly declared itself satisfied with the financial relations between the hospital and the medical school. After some discussion the amendment was lost by 18 votes to 38 and the report carried by an overwhelming majority. The council for the year was re-elected, with the addition of the Rev. W. S. Swayne, and Sunday, June 18th, was fixed for Hospital Sunday next year. The proposal to increase the percentage of the Fund allocated to the purchase of surgical appliances from 5 to 7½ per cent. was adopted unanimously, and a vote of thanks to the Lord Mayor terminated the proceedings.

SOME FAILURES WITH "606" IN RUSSIA.—At a meeting of the Public Health Society, St. Petersburg, Dr. P. P. Yakoblieff gave a report on the Ehrlich preparation "606" and its application to children at the breast and to nursing mothers. He described six cases involving six children, of whom three were injected directly, and the nursing mothers of the other three were similarly treated. In neither series was the rapid betterment noted that has been ascribed to the remedy elsewhere. In the cases of the direct injections, ulcers were formed and the remedy was slowly absorbed. Only two of them appeared to improve, and that very slowly. In the third case no difference at all was observed. In the cases of the nursing mothers the eruptions subsided and began to heal, but did not disappear. In the discussion following on the reading of the report Professor V. O. Hubert said that the disappointing results might be due to special conditions, such as insufficient doses of the remedy. But even he had to report a case of a young man, aged 18 years, who, duly inoculated, relapsed after a short time. Other speakers confirmed the ineffective result of arsenobenzol in cases of infants at the breast.

THE LEAGUE OF MERCY.—On Dec. 19th, at the Middlesex Hospital, Lord Farquhar presided over the eleventh annual meeting of presidents of the league. In opening the proceedings the chairman read a letter from the King's secretary, in which His Majesty expressed his unabated interest in the work of the League of Mercy. On the motion of Mr. Carl Hentschel, seconded by Mr. B. S. Straus, Lord Farquhar was appointed chairman of the next annual meeting, Mr. Frederick Green vice-chairman, and Colonel H. B. Hamilton honorary secretary. In his financial statement Sir Henry Burdett, honorary treasurer, said that the year had been a bad one for the purposes of the league. The total result of the collections had been £20,000, as compared with £21,606 last year. The total amount contributed by the league to the London hospitals through the King's Fund in the last 11 years was £153,000. The total the league had given to the country hospitals was £7660, making a grand total of £160,000. The districts presided over by members of the Royal Family had produced a total of £27,238. The Duchess of Somerset suggested the formation of sub-committees for the purpose of organising bodies of workers on behalf of the league, and asked for an assurance that the money collected by the League was spent solely in the interests of the sick poor. Sir William Collins said, on the authority of those responsible for the management of the King's Fund, that no money handed over by the League to the Fund was diverted to medical schools.

BOOKS, ETC., RECEIVED.

AMERICAN MEDICAL PUBLISHING CO., 84, William-street, New York City.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BREWIS, ROBERT ADAMS, M.D., C.M. Edin., has been appointed Medical Officer of Health by the Dursley (Gloucestershire) Rural Council.

CAMPBELL, R. H., M.B., B.S. Glasg., has been appointed Clinical Assistant to the Samaritan Free Hospital.

DUNN, J. C., has been appointed Clinical Assistant to the Samaritan Free Hospital.

HEATON, GEORGE, M.B. Oxon., F.R.C.S. Eng., has been appointed Examiner in Surgery to the University of Oxford.

JOLL, CECIL A., M.B., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond., L.D.S. Eng., has been appointed Senior House Surgeon to the Leicester Infirmary.

LEY, BERNARD, M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Samaritan Free Hospital.

LYLE, H. WILLOUGHBY, M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Ophthalmic Surgeon to King's College Hospital.

MEACHEN, G. NORMAN, M.D., B.S. Lond., M.R.C.P. Lond. & Edin., has been appointed Honorary Physician for Diseases of the Skin to the Foundling Hospital, London.

MOISER, LIONEL HENRY, M.B. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Central District by the Crediton (Devon) Board of Guardians.

SHANNON, DAVID, M.B., B.S. Glasg., has been appointed Visiting Surgeon to the Royal Samaritan Hospital for Women, Glasgow.

STEPHEN, LESLIE DECHMONT, M.B., C.M. Edin., has been appointed Deputy Medical Officer for the Nunney District by the Frome (Somerset) Board of Guardians.

TODD, DAVID BANSALL, M.B., B.Ch. Oxon., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer by the Kingsbridge (Devon) Board of Guardians.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRISTOL DISPENSARY.—Medical Officer.

BRISTOL ROYAL INFIRMARY.—Dental House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

CAIRO, EGYPT.—Medical Tutor at School of Medicine and Registrar to Kasr-El-Ainy Hospital. Salary £E.600 a year.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—House Surgeon for six months. Also Second House Surgeon.

CANCER HOSPITAL, Fulham-road, London, S.W.—Surgical Registrar. Salary 50 guineas per annum. Also House Surgeon for six months. Salary £70 per annum.

CHELTENHAM GENERAL HOSPITAL.—Resident Surgeon. Salary £180 per annum, with rooms, coal, and gas.

DERBYSHIRE ROYAL INFIRMARY.—House Physician and Second House Surgeon for 12 months. Salary in each case £100 per annum, with apartments, board, &c. Also Assistant House Surgeon for six months. Salary at rate of £60 per annum, with apartments, board, &c.

DUBLIN JOINT HOSPITAL BOARD CONSUMPTIVE SANATORIUM, Crooksling, Brittas, Co. Dublin.—Resident Medical Superintendent. Salary £200 per anuum, with board and residence.

EARLSWOOD ASYLUM, Redhill.—Junior Assistant Medical Officer, unmarried. Salary £130, with board, lodging, and washing.

ESKDALEMUIR PARISH COUNCIL.—Medical Officer. Salary £30 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—Clinical Assistants for three months. Also House Surgeon. Salary at rate of £60 per annum, with board, residence, and washing.

HAMPSTEAD GENERAL HOSPITAL.—House Physician for eight months. Salary at rate of £70 per annum, with board and residence.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Assistant Casualty Medical Officer (and House Physician), unmarried, for six months. Salary £30, with board, residence, &c. Also House Surgeon, unmarried, for six months. Salary £30, with board, residence, &c.

LINCOLN, LINDSEY COUNTY COUNCIL.—Assistant School Medical Inspector. Salary £300 per annum.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—Honorary Assistant Surgeon.

LUTTERWORTH UNION.—District Medical Officer and Public Vaccinator. Salary £40 per annum.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Parkplace, Cheetham Hill-road.—Honorary Ophthalmic Surgeon. Also Anæsthetist. Salary £15 per annum.

NATIONAL HOSPITAL FOR THE RELIEF AND CURE OF THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.—Honorary Anæsthetist.

NEWCASTLE-ON-TYNE, HOSPITAL FOR SICK CHILDREN.—Honorary Assistant Physician.

NEWCASTLE-UPON-TYNE, CITY HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Assistant. Salary £125 per annum, with board, lodging, &c.

NEWCASTLE-UPON-TYNE EDUCATION COMMITTEE.—Second Assistant Medical Officer. Salary £250 per annum.

PADDINGTON AND KENSINGTON DISPENSARY FOR THE PREVENTION OF CONSUMPTION.—Assistant Medical Officer. Salary £100 per annum.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Surgeon.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

READING, BERKSHIRE EDUCATION COMMITTEE.—Assistant Medical Inspector of Schools. Salary £300 per annum.

ROTHERHAM HOSPITAL.—Senior House Surgeon. Salary £110 per annum, with board, lodging, and washing.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square.—Honorary Dental Surgeon. Also Honorary Anæsthetist.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SOUTHAMPTON, FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.

SUNDERLAND INFIRMARY.—House Physician. Salary £80 per annum, with board, residence, and washing.

WEST LONDON HOSPITAL AND POST-GRADUATE COLLEGE, Hammersmith-road, London, W.—Clinical Assistants. Also Three non-resident Assistant House Surgeons.

Births, Marriages, and Deaths.

BIRTHS.

DAVIDSON.—On Dec. 18th, at Baron's Court-road, W., the wife of G. G. Davidson, M.D., of a daughter.

SIKES.—On Dec. 12th, at Moat House, Langley, Bucks, Mary Maitland (*née* Somerville), wife of Alfred W. Sikes, M.D., D.Sc. Lond., of a son.

MARRIAGES.

ELLIOT—LOVEDAY.—On Dec. 17th, at St. Mary's Church, Bryanston-square, by the Rev. C. V. Childe, M.A., LL.D., and the Rev. L. J. Percival, M.A., Andrew Elliot, M.D., M.R.C.P., of 110, Gloucester place, Portman-square, W., to Mary Louisa, younger daughter of William Loveday, Esq., of The Poplars, Irthlingborough, Northamptonshire.

FENWICK—STOCKDALE.—On Dec. 17th, at St. Martin's-in-the-Fields, Trafalgar-square, by the Rev. H. Rose, M.A., William Stephen Fenwick, M.S., F.R.C.S., 81, Harley-street, W., only son of Thos. Fenwick, of Southampton, to Enid Stockdale, third daughter of Thos. Stockdale, Spring Lea, Leeds.

HAWKINS—RYND.—On Dec. 17th, at St. Mary's, Kells, Co. Kilkenny, Herbert Pennell Hawkins, M.D., F.R.C.P., to Hester Vera Rynd, niece of Colonel W. H. Izod, D.L., J.P., of Chapel Izod House, Co. Kilkenny.

OUSTON—TAYLOR.—On Dec. 16th, at St. Andrew's Church, Bath, by the Rev. Prebendary Stone, Thomas George Ouston, F.R.C.S., of Newcastle-upon-Tyne, to Mary Taylor, second daughter of Edward Taylor, of Ayrton, Yorkshire.

DEATHS.

BRUSHFIELD.—On Nov. 28th, after a short illness, at his residence, The Cliff, Budleigh, Salterton, T. N. Brushfield, M.D., F.S.A., formerly Superintendent at Chester and Brookwood Asylums, aged 81.

POLLOCK.—On Dec. 18th, at 37, Collingham-place, S.W., James Edward Pollock, M.D., F.R.C.P., in his 93rd year. Funeral at Highgate Parish Church, Thursday, Dec. 22nd, at 2 o'clock, and burial in Highgate Cemetery.

STAVELEY.—On Thursday, Dec. 15th, at 24, Sloane-gardens, in his 48th year, William Henry Charles Staveley, F.R.C.S., son of the late T. G. Staveley, Esq., of the Foreign Office.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

RESCUE WORK IN MINES.

Mr. R. A. S. Redmayne, M.Sc., Chief Inspector of Coal and Metalliferous Mines, in his report to the Home Office for 1909, just issued as a Parliamentary paper, refers to the recommendation of the Royal Commission on Mines that in each district there should be appointed committees of colliery owners to provide for the erection of stations and training of men, and that a handbook might be drawn up containing instructions in rescue work. He records with satisfaction that there has been an increased and welcome desire evinced on the part of coal-owners to meet the needs of colliery districts in the establishment and organisation of stations for the training of rescue brigades, in the use of breathing appliances, and in general mine rescue work. The improvement is, however, much more marked in some districts than in others. Mr. Redmayne selects for special commendation the system in operation at Howe Bridge Rescue Station in Lancashire, which is enjoying the support of a large majority of the Lancashire and Cheshire coal owners. The station in question is now in complete working order. Since the training was started on Oct. 26th, 1908, no fewer than 269 men, drawn from 30 different firms, have been trained, and of these 136 have passed their re-examination, which is held 12 months after the teams have qualified in the use of the apparatus and obtained their certificates, and about 50 men are at present undergoing the course of training. The type of apparatus used is the (Siebe Gorman) "Fleuss," slightly modified in respect of certain details. A code of recommendations and rules has been drawn up with a view to ensuring proper discipline, and so limiting the rescuers to only unavoidable risks. Amongst these recommendations and rules are the following:—

The men chosen for rescue work should be intelligent, healthy, from 25 to 50 years of age, should be ambulance trained and kept efficient in ambulance work. They should not be of a nervous temperament, and the teams should be chosen from the different shifts of surface as well as underground workmen, and all should reside as near the colliery as possible. Before admission for training all men must be medically examined, and the examination should be repeated each year. With the view of maintaining the efficiency of the teams, periodical practices with the apparatus, both at the colliery and the station, are recommended. The following apparatus and stores should be provided and maintained at every colliery in constant readiness for use:—

1. Seven, but not less than five, complete sets of apparatus with oxygen cylinders ready charged. Each man should have his own mouthpiece, to be kept on a peg, with his name written over it.
2. Spare oxygen cylinders fully charged.
3. Supply of best anhydrous caustic soda in hermetically sealed bottles.
4. Spare nose clips, masks, and mouthpieces.
5. Goggles for use in smoke.
6. The necessary electric lamps, with spare accumulators.
7. An oxygen reviving apparatus.
8. A regulation sling chair or saddle for descending the shaft when the cages are jammed or not available.
9. A regular stretcher.
10. A first-aid ambulance case.
11. A few tins of compressed sulphurous acid.

It is advisable that at each colliery there should be some room prepared which could be simply and quickly rendered comparatively air-tight and converted into a testing-room, where each man could test his apparatus in a noxious atmosphere. For this purpose a few tins of compressed sulphurous acid should be kept with the other stores. It is also advisable that a convenient room or rooms should be selected at each pit, which in case of accident could quickly be prepared for the accommodation of the rescue teams, and where they could wait their turn, eat, and, if necessary, sleep. It is very desirable that an interval of three hours shall have elapsed since the last meal before a man works with the apparatus. The man appointed by the colliery to be responsible for the upkeep of the apparatus, or the sergeant-instructor of the station, shall go through the following list of cardinal rules one by one with each member of the team in turn previous to his using the apparatus:—

(*a*) Before putting on apparatus inquire if each man is in his ordinary state of health. False teeth to be removed. At least 120 atmospheres to be in the oxygen cylinder. Four pounds of hard dry pure caustic soda to be in the breathing bag. All joints to be tightly screwed up and rigid. Try the three valves (main, gauge, by-pass) and see that they work freely.

(*b*) After putting on apparatus, buckle belts and adjust the apparatus, leaving nose clip off. Test the apparatus by turning on main valve, fill breathing bag three parts full, close main valve, close the mouthpiece at the same time with the tongue, then press the bag evenly with both hands, and listen for any escape of gas. On removal

of the hands, see that the bag is in the same condition—viz., that it holds the same quantity of gas. Put nose clip on and test apparatus in room provided filled with noxious gas. An electric lamp, a pair of goggles, and a lump of chalk should be carried by each team, and a small metal flask of brandy by No. 2.

When exploring, the distance between each man should not exceed four yards, and the whole team must keep absolutely together. Unless expressly ordered by the manager, no team must advance more than 200 yards from the base, nor be absent for a longer period than 20 minutes. Any hard work should be equally shared, if possible, so as to equalise the supply of oxygen in the cylinders. As soon as any member of the team has used up one-half of his supply of oxygen the whole party must return. No man must use the apparatus more than one shift of two hours in every 24 hours. In no circumstances should the mouthpiece be removed after leaving the base. When one member of the team breaks down from any cause the whole party must return at once. Should any member of the team feel distressed he should report the same on his return to the officer in charge, and should not be asked to use the apparatus again until he has submitted himself for examination by the medical officer.

The inspector mentions that there are several types of breathing apparatus in use at rescue stations, and opinions differ as to which is the most efficient. At several centres experiments are being carried out with a view of determining the merits of the respective types, and the council of the Royal Society of Arts, with a view of encouraging research in this direction, has offered a gold medal or a prize of £20 for life-saving in mines under certain conditions.

In reference to the remark of the Royal Commissioners that a knowledge of ambulance work or "first-aid" is probably of greater value in mining than in any other occupation, Mr. Redmayne observes:—"The work already carried out by the Order of St. John of Jerusalem in England and Wales, and in Scotland by the St. Andrew's Ambulance Association, is well known, and in respect of the Durham and Yorkshire mining districts has been especially marked. In the former district the number of persons employed in and about mines and quarries holding first-aid certificates was 3517, and 5257 cases of injury were treated during the year, the number of classes held during the year being 68, which were attended by 1155 students, of whom 494 obtained certificates. Although throughout the mining districts generally greater interest now appears to be taken in ambulance work than was the case a few years ago, the subject should be far more widely taught than it is, and colliery owners and managers can do much to awaken and stimulate interest in the work at their mines by organising competitions as between collieries and providing prizes, whilst if the officials of miners' unions would urge upon their members the desirability of interesting themselves in the work there can be no doubt that it would further advance matters."

SCENT IN TOBACCO.

IN our issue of Nov. 12th, 1910, we commented upon the objectionable practice of scenting tobacco so universally adopted by the modern tobacco manufacturer. At the time of writing we were not aware of the exact formula of scents used for the purpose, but in the *Pharmaceutical Journal* of Dec. 10th the following appears as an answer to a correspondent:—"*Tobacco Flavours.* The following are recognised formulæ: (1) Cascarilla, 4; liquid extract of valerian, 4; Tonquin bean, 1; rum, 12. Macerate for three or four days. (2) Tincture of cascarilla, 48; essence of Tonquin beans, 32; tinctures of tolu, orris, and valerian, of each 16; oil of nutmegs, 4; oil of cloves, 2; oil of rhodium, 1. (3) Cascarilla, 2; valerian rhizome, 1; Tonquin bean, 2; orris rhizome, 1; alcohol (60 per cent.), 40. Macerate for seven days." No wonder, as we wrote at the time, "the fragrance of pure honest tobacco is to most smokers a mere memory"!

A LABORATORY BOY ON THE NATIVE MEDICAL STUDENT.

WE have received from a correspondent the following extract from a letter to him written by his former laboratory boy, who has gone out to a laboratory in one of our Crown Colonies in the Pacific:—

"As we have got everything in working order things go smoothly. I have been for a month's trip around these beautiful islands, and was enchanted with everything I saw. It was so strange, so different to what I expected. I have dreamt of seeing all these strange things, and now realization comes as a great surprise. I am indeed lucky to have had the chance. I wish all the boys could have come, for at any rate it broadens one's mind.

"I get to like the natives, although they appear as a set of babies. They are indeed a happy race, always jolly and very kind. The Government here are trying to make medical men of some, but I think it will be a failure, for all they think about is to drink and eat. The students—there are 20 of them—are trained at the hospital near. I have one of them to help me, Jessie by name, and he looks like a huge gorilla. He washes the tubes, slides, &c., and wants continually watching. How different they are to medical students at home, for they run anywhere for a sixpence. I was amused the other day at the medical officer parading them all and trying to find out which had had a bath. One poor wretch who said he had was not believed, so they all had to go and have one then and there."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
" 23rd (Paris).—First Congress of French Medical Journalists.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
" 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
" 19th–22nd (Wiesbaden).—Twenty-eighth German Congress o Internal Medicine.
" 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.
May–October (Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
" (Turin).—International Congress of Pathology.
Sept. 11th–15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Goultes de Lait*).
" 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 18th–23rd (Sydney).—Australasian Medical Congress.
" 18th–24th (Turin).—Fourth National Congress of Hygiene.
" 24th–30th (Rome).—International Congress on Tuberculosis.
" 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Genoa).—International Exhibition of Marine Hygiene.
(Date not fixed) (Rome).—International Exhibition of Social Hygiene.
(Date uncertain) (Turin).—International Exhibition of Industry and Labour.

In 1912:—
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
" Visit of German Medical Men to America.
Nov. 22nd–29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—
(London).—Seventeenth International Congress of Medicine.
(Dresden (?)).—International Conference on Cancer.
August (Buffalo).—Fourth International Congress of School Hygiene.

In 1915:—
(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.
THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (28th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (29th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor. 9 A.M., Major, 2 P.M.).

SATURDAY (31st).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

A Lecture
ON
OBESITY AND CERTAIN CHANGES OF METABOLISM.

Delivered at the Medical Graduates' College and Polyclinic on Oct. 27th, 1910,

BY DR. O. ROZENRAAD,
PHYSICIAN AT HOMBURG.

GENTLEMEN,—The last time I had the honour of lecturing to you my subject was on the recent advances of diabetes and glycosuria. To-day I have chosen as a subject "Obesity and Certain Changes of Metabolism," which is in many ways connected with the above-named disease. Having carried out last winter with Professor Moritz, at the hospitals in Strasburg, some scientific research work on the fluid contained in fat cells, I am glad to attempt to throw some new light on the etiology of obesity.

Obesity and glycosuria are kindred diseases; about 50 per cent. of all obese persons suffer from glycosuria, though this seems to have little prognostic value. With glycosuria heredity is an important factor in its etiology; sometimes we find that diabetes and obesity are combined with a neurasthenic disposition. A neurasthenic person may be obese, or an obese person may be neurasthenic; it is not always necessary that a neurotic be thin, though in the majority of cases obese persons are not neurasthenic. A good amount of weight may tend to the well-being of a person, but corpulency is not a sign of good health. Obese persons die young, a fact well known to the insurance companies, and they do not recover well from the effects of surgical operations. The disease of obesity itself produces during lifetime cardiac troubles and arterio-sclerosis, also physical and mental inactivity.

The very fact that fat people do not move about much tends to increase their weight; every pound they gain is a vicious circle. For instance, if a person puts on only 7 grammes per day she gains 200 grammes per month or 6 pounds a year, but the next year she will gain more than those 6 pounds, and the increase will be more than an arithmetical progression.

The primary cause of obesity lies in a misproportion between the energy taken in the food and the amount expended by the body. The remainder of the food, not burnt up and lost as heat and work, is stored up as fat. It is Oertel's merit to have pointed out to the profession how much benefit cardiac cases receive by a reduction of weight. In some cases the patients have entirely recovered from asthmatic troubles and emphysema; even cases of locomotor ataxia and kyphoscoliosis are reported by von Noorden to have markedly improved after reduction of weight.

The difference formerly made between anæmic and plethoric obesity has been given up; the distinction now made is whether the case is a case of endogenous or exogenous metabolism. As endogenous have to be considered all cases in which combustion is abnormally low, when dieting has no effect, and thyroid extract as a stimulant for the oxidising process has to be resorted to.

From the chemical structure of the fat cell we can understand that the oxidising process is a slow one. Here is the formula of tri-stearin:—

$$C_3H_5(C_{18}H_{35}O_2)_3,$$

one of the chemical compounds of the fat molecule. As the carbon molecules are high, the oxygen molecules low, it must take time until it is burned into carbon dioxide and water; carbohydrates, as we know, and proteins contain more oxygen and less carbon, therefore burn more easily. This explains why the caloric value of fat is 9, of albumin only 4. What becomes of the fat molecules absorbed? The fat is digested by the pancreatic juice, then changed into glycerine and fatty acids, which after emulsification of the fat are brought by the hepatic veins to the liver. Part of it is transformed into a carbohydrate by a synthetic process which we do not yet know; part of it is absorbed by the blood and tissues and stored up in the organism. The panniculus adiposus of the skin, especially of the abdomen, is a favourite deposit for the fat—the kidneys and the heart, too. There are parts of the organism where no fat deposit ever is found—the scrotum, labia, &c.

TREATMENT.

The treatment of obesity means underfeeding a patient on dietetic principles. Of the various methods I need only to point out to you the Banting, Weir-Mitchell, Oertels, von Noorden, and Karell's cures. Their difference lies in the amount of food to be given to the obese.

Methods.	Proteids. Grammes.	Carbohydrates. Grammes.	Fat. Grammes.
Banting	172	87	8 = 1100 Cal.
Oertel	156	75	25 = 1180 ,,
Ebstein	102	47	85 = 1300 ,,
Von Noorden	120	35	118 = 1300 ,,

In the Banting cure the amount of fat is unusually low—only 8 grammes—whereas with Ebstein and von Noorden it is very much higher, but the amount of carbohydrates is low in proportion—about 35 grammes. The Banting cure means a severe cure, and the amount of 1100 calories is small, whereas Ebstein's diet answers more to the taste of the patient, who does not like to feel he is hungry.

Von Noorden's diet is still richer, and the only amount of food to be severely reduced are the carbohydrates. It answers very well if the patient be under the strict dieting of a medical man—i.e., in a sanatorium or private nursing home, where the proper amount of food may be weighed and nitrogenous substances of the urine examined in a laboratory; but this means for the patient great expense both in time and money, and the practitioner, unless he be a specialist on the subject, will often find it difficult to know and remember the exact caloric value of every food. But it is to the persons of limited means we have to devote our attention, and for them I think Karell's cure is preferable, for with it a patient may be treated at his own home.

Karell's cure is very useful in cases of cardiac trouble, Bright's disease, especially when combined with gout, when a diet containing no salt is advisable and œdema exists, for milk has a diuretic effect. Karell's cure is a milk diet, the essentials of which are that 2000 cubic centimetres of milk are given to a person who has a metabolism of about 3000 calories. In Karell's cure, in order to avoid too great a combustion of proteins, carbohydrates—viz., potatoes—have to be given occasionally, for proteins do not burn as rapidly when they are "protected" by a carbohydrate food. May I give you here in tabulated form a case treated by Karell's cure?

Case of a Female Patient, 44 years of age and 165 Centimetres in Height.

Date.	Weight (kgms.).	Milk (c.cm.).	Calories.	Days.	Loss of weight (kgms.).	Per day (kgms.).
9/1	94·5	2000	1300	3	2·1	0·7
12/1	92·4	2000	1300	11	0·8	0·07
23/1	91·6	1800	1170	1	0·4	0·1
27/1	91·2	1750	1140	3	0·3	0·1
27/1	90·9	1500	925	11	1·9	0·17
7/2	89·0	1200	872	1	0·3	0·3
8/2	88·7	1500	975	13	3·5	0·13
21/2	85·2	—	—			—
				43	9·3	

Karell's milk cure has recently been re-introduced into therapeutics by Jacob and Moritz. Through this milk diet a great quantity of liquid is evacuated from the organism of the human body; a basis is thus formed on which further reduction in weight is more easily obtained by subsequent cures. The quantity of milk to be given depends on the weight of the patient; as an instance, we may reckon that a woman of 150 centimetres would have a weight of 50 kilogrammes; the quantity of the milk to be given would thus be reckoned by multiplying the centimetres above 100 by 25 = 1250 cubic centimetres. If there is a loss of 50 grammes of nitrogen during the cure, this means 310 grammes albumin, or 1650 grammes meat. If we have a loss of 10,000 grammes during reduction, we have to deduct 1650 grammes of meat. Thus there remains 8350 grammes for

the fatty substances, but these 8350 are not pure fat, but fat mixed with water. This explains why patients gain their normal weight after the cure is over—for there remains a great amount of water in the tissues and retention of sodium chloride in the body.

We have to discover what amount of water is contained in the fatty substances. There have been previous investigations of this subject, but with very unsatisfactory results. I have therefore undertaken to examine the fat in post-mortem cases as well as with patients immediately following an operation, for instance, extirpation of the mammæ. I examined 21 post-mortem cases and two cases following operations at the Pathological Institute of the Strassburg Hospital. My procedure was to take 5 grammes of fat instantly after dissection, which was then weighed on a chemical scale and placed in an incubator at a temperature of 110° C. for 48 hours; it was then transferred into an exsiccator for 24 hours, and then weighed again. The loss indicated the percentage of water in the specimen.

Case.	Sex.	Years of age.	Cause of death.	Percentages of water.			
				Fat layers of abdomen.	Heart.	Kidneys.	Femur.
1	F.	45	Cancer of intestines.	6·0	—	10·2	—
2	M.	41	Erysipelas.	7·88	—	—	—
3	F.	51	Endocarditis.	7·88	—	—	—

The results of my experiments tend to show 13 per cent. of liquid substance in the fat cells, but there is a slight difference if the fat is taken from the heart, the abdomen, or the kidneys. With the fat of the heart there seems to be a slight increase of the water. May I call your attention to Case 9. Between the amount of water in the fat cells close to the metastasis of a carcinoma and the fat at some distance was a difference of 7·2—in the first 12·2 and the second 19·4. In carcinomatous patients there are an increase of the liquid substances in the organism and formation of an œdema against the toxins produced. Voit stated that 30 per cent., Volkmann estimates 15 per cent., of water is contained in the fat cells; thus my experiments would verify Volkmann's calculation. You will find a difference between persons who are ill-nourished or cachectic and well-nourished. The amount of the water contained in the fat cells was about 7 to 14 per cent. (see Cases 2 to 9), though the fat layer measures sometimes almost an inch, but with the cachectic the amount of the water was higher (see Cases 16 to 21).

With the two specimens taken from persons immediately following operations (extirpation mammæ due to tumour) the amount of water was 13 and 22 per cent. Please notice that persons in whom a high percentage of water was found were old. A fact proved by Ranke was that the organs contain more liquid in old age, and therefore the fat cells naturally become charged with water as well.

With cachectics the tissues become impregnated with a kind of gelatinous substance especially the fat cells. We can understand this as it is quite natural that in a person suffering from a malignant disease the reserves of fat are consumed by the disease and the fat cells replaced by an albuminous liquid.

Becquerel, Rodier, and von Hosslin had similar results with the blood and tissue of carcinomatous and tuberculous cases, where there was an abnormal increase of the liquid substance.

The low amount of water contained in fat cells gives us an explanation why it is practically of no difference whether the amount of liquids be reduced in the diet—with 13 per cent. of water contained in fat cells it is of no importance whether liquids are given or not—the fat cells do not take more fluid—and would not be influenced by a reduction of liquid given.

Now, if we reckon a 13 per cent. amount of water in fat and take this into consideration in the balance of calometric equilibrium we would have the following results. During a period of 48 days a patient lost 50 grammes nitrogen, which corresponds to 310 grammes albumin, or 2920 grammes flesh. The loss of weight during these days was 12,000 grammes; deduct for flesh 2920 grammes, and there remain 9080 grammes, of which, with a 13 per cent. amount of water in fat, 639 grammes are water; thus 8441 grammes of pure fat have been lost, or 175 grammes a day. 175 grammes a day of fat give 1627 calories; thus if we put 1627 calories lost through weight in our calculations we have 1300 calories of the milk, 1627 calories lost, making 2927 calories, about the daily amount of calories necessary for one person.

As I said before, Karell's cure, which has lately become very popular on the continent, may form the basis for a further cure on Weir Mitchell's, Ebstein's, or von Noorden's principles. I need not point out to you that Weir Mitchell's treatment is a cure in which milk and proteid food is combined, during which milk and eggs are given, half a pint of milk and an egg every three hours, five or six times within 24 hours; but it may be more to the advantage of the patient to feed him on a richer diet, for the patient may soon get tired of underfeeding himself on a very strict line, and then give up the cure entirely, and therefore Ebstein's diet is advisable. As the French say, "l'appetit vient en mangeant." The diet should consist principally of meat, avoiding pork, goose, duck, and fat smoked beef; fish is allowed except salmon, lobster, sprats, herrings; toasted bread or rusks are preferable to fresh bread; no cake or biscuits. As to vegetables—potatoes, carrots, turnips, beans or peas are not allowed. Vegetables should not be cooked with butter or oil. Not allowed compôtes, dried fruit; no cheese. No soups, chocolates, cocoa, brandy, whisky, or champagne.

A drawback of all cures to reduce weight is that constipation soon takes place, due to the scarcity of food given, and as about 15 per cent. of the dried substances of the fæces consist of neutral fatty acids non-absorbed they cause a peristaltic movement and their elimination causes constipation. Remedies for constipation have to be given during the cure.

During a cure all alcoholic drinks ought to be reduced. The theory of reducing the liquid is antiquated, and plenty of ordinary water or mineral water may be allowed. It is Yorke Davies's merit to have pointed out that a reduction of fluid was not advisable at a time when Oertel insisted on great reduction of all fluid.

A great help in the treatment of obesity is a cure in a health resort, for there a dietetic cure may be taken under

better control than at home, and drinking the waters, combined with plenty of exercise, massage, and Turkish baths, reduce the obese quickly. Harrogate in England, Brides-les-Bains in France, Homburg, Carlsbad, and Marienbad on the Continent are some of the favourite resorts, "récherché's," by the obese. Patients are very apt to take too much of these waters in order to get thin soon. In my practice in Homburg I knew an American lady to take seven glasses of the Homburg waters in order to get thin fast. Needless to say, she collapsed after a week and was severely ill for some time.

The effect of taking the waters at spas like Homburg or Marienbad would be an ephemeral one unless the patients were taught how to diet themselves afterwards. In Homburg great attention is given to dieting; every hotel keeper and proprietor of a lodging-house is supplied with the necessary forms of diets, and special cooking is arranged. Some devote themselves exclusively to this dietetic task, and diabetes or gout is treated on the same dietetic line. The advantage of the Homburg waters is that they are purgative, a valuable item in the diet of the obese, who are apt to suffer from constipation, the Elisabethen spring containing 9 per 1000 of chloride of sodium, the Landgrafen Brunnen about 11 to 1000. I need not speak of their effect, for their laxative effect in colitis, the increase of hydrochloric acid in cases of anacidity of the gastric juice, is well known. Combined with these waters, the climbing of the hills, the carbonic acid baths, and the mud applications are beneficial in this cure. Homburg, being situated at an altitude of 800 feet, is especially beneficial by its bracing air to the cases of anæmic obesity, the amount of hæmoglobin increasing at a considerable altitude.

Should a dietetic cure not lead to satisfactory results treatment with thyroid is indicated, but in many cases thyroid is advised when the diet alone would have helped the patient, if carried on for a certain length of time. For there are cases in which the retarded metabolism of obesity does not seem to yield to a dietetic treatment, and patients, though undergoing a course of diet for a length of time, say that they are fed with only 900 calories, do not lose weight. These cases are due to a constitutional tendency, and they are cases to be treated with thyroid. The reduction of weight soon takes place and they remain less obese. During this treatment we have to watch the action of the heart and the pressure of blood; should the pulse increase, it would be advisable to discontinue this treatment. The amount of thyroid to be given, as a rule, is three grains, three times a day during the meals for a couple of weeks. No thyroid ought to be given in the climacteric age.

I may mention that there are relations between corpulency and secretions of the hypophysis gland. The extract of the hypophysis, the pituitary extract, is able to reduce corpulency as well as the thyroid extract. These facts show a relation between obesity and internal secretion of these glands.

In former days much importance was given to sexual obesity; the extirpation of the testes seemed to produce corpulency—the eunuchs of the Turkish harem were always quoted. Yet even complete withdrawal of the ovaries or testes may have no effect on the metabolic process. I refer here to an experiment of Luthje, who examined during one year the carbon and mineral metabolism of castrated and normal dogs, and determined the total composition of the bodies. No difference whatever could be found between the normal and pathological animals.

There exists one form of obesity, called adiposis dolorosa, or Dercum's disease, when adipose tumours form and pains occur. This kind of obesity causes atrophy of the muscles and debility of the nervous system. It is not very frequent on the continent.

Von Noorden, in Vienna, says that these cases of retarded metabolism, or "endogenous obesity," as he calls them, are about 20 per cent. among the Jews and 5 per cent. among the Caucasian races; and as obesity is very frequent among the Jewish race he attributes it to their tendency to marry in their own race.

It may look easy to reduce weight by underfeeding, but it is very difficult for the patient to maintain this reduced weight without suffering from general weakness. However great the number of patent medicines used by the public may be, none answers so well as carefully dieting a patient. We know too well that the lines of diet are the only ones to be followed in reducing obesity, and it is our duty to educate the public to this standard.

Gentlemen, I do not propose to put before you any dietary "cure" which a specialist has established, for common sense is the line upon which the diet has to be carried out. Every case has to be individually treated and the diet very carefully watched. It is therefore of importance that the carrying out of the diet be observed by the medical man, and not left to the will of the patient. A good surgeon knows when not to operate, a good physician knows when reduction of weight is no longer necessary, for the patient too often wishes to be reduced in weight in a very short time—a mistake that might soon be followed by general weakness due to muscular debility of the heart.

A SIMPLE SERUM DIAGNOSIS FOR TUBERCLE; ALSO A METHOD OF OBTAINING AN IMMUNITY INDEX.

BY V. B. NESFIELD, F.R.C.S. ENG., L.R.C.P. LOND.,
CAPTAIN, INDIAN MEDICAL SERVICE.

WITH a view to discovering traces of immune substance in the serum of tuberculous patients I carried out a series of tests, taking as my basis the fact that the immune body[1] combines with its specific bacterium or toxin, and that this bacterium-immune compound unites with complement.[2] It is the principle employed by Wassermann for the diagnosis of syphilis.

The reactions may be represented by the chemical interactions of three simple substances, which will perhaps explain more clearly these interactions than by referring to Ehrlich's organised looking bodies, with side-chains, &c. Thus let the bacterium be represented by zinc carbonate, $ZnCO_3$; the complement by sodium sulphide, Na_2S; the immune body by sulphuric acid, H_2SO_4; and sheep's red blood corpuscles by lead nitrate, $Pb(NO_3)_2$. $ZnCO_3$ and H_2SO_4 form a compound which combines with Na_2S.

Thus—

$$\underset{\text{Zinc carbonate. Bacillus.}}{ZnCO_3} + \underset{\text{Sulphuric acid. Immune body.}}{H_2SO_4} = \underset{\text{Zinc sulphate. Bact. imm. comp.}}{ZnSO_4} + CO_2 + H_2O.$$

$$ZnSO_4 + \underset{\text{Sodium sulphide. Complement.}}{Na_2S} = \underset{\text{Zinc sulphide.}}{ZnS} + Na_2SO_4.$$

$ZnCO_3$ cannot combine with Na_2S without the intervention of H_2SO_4.

Now, if to this mixture of bacterium ($ZnCo_3$), immune body (H_2SO_4) and complement (Na_2S) some lead nitrate (sheep's corpuscles) be added, no black lead sulphide will be formed (no hæmolysis). But if the immune body be excluded from the mixture, a black precipitate of lead sulphide will result (hæmolysis).

Thus—

$$ZnCO_3 + Na_2S + Pb(NO_3)_2 = ZnCO_3 + \underset{\text{Lead sulphide.}}{PbS} + 2NaNO_3.$$

It will be seen by the equation that 1 molecule of immune body (H_2SO_4) absorbs 1 molecule of complement (Na_2S) in the presence of its specific bacterium ($ZnCO_3$), and if there is more complement present than immune body, some complement (soluble sulphide) will remain unabsorbed and will produce blackening with lead nitrate, and thus the trace of immune body is likely to be overlooked.

In tubercle there are frequently only very small traces of immune body, usually one-fifth part of the complement present.

Special Points Affecting the Reaction.

1. Normal human serum hæmolyses sheep's red blood corpuscles—i.e., it contains an amboceptor for sheep's red cells.
2. Complement is destroyed by moderate heat, immune bodies are not.
3. Tubercle bacilli emulsion does not absorb complement, nor does it hæmolyse sheep's red corpuscles.
4. Sheep's corpuscles when washed three times do not contain complement.

[1] Known also as "amboceptor," "intermediary," "preparer," "fixateure," and "sensibilisatrice."
[2] Known also as "alexin" and "addiment." (Hewlett's Bacteriology).

5. The complement is very active, and its power of hæmolysing is not appreciably decreased by diluting 20 times.

6. The quantity of sodium chloride present is a very important detail. If human serum is diluted 5 times with 1·5 per cent. sodium chloride, it does not hæmolyse sheep's red cells, but will do so even 12 hours later, if diluted enough to make 1 per cent. With 1 per cent. salt hæmolysis occurs, but the best results are obtained with 0·5 per cent. salt. When the corpuscles are old 0·75 per cent. salt must be used.

The explanation of this may be: (1) With 0·5 per cent. salt the pellicles of the red cells are put slightly on the stretch (0·8 per cent. salt being normal), thus requiring only a little disintegration to bring about their rupture, and conversely with 1·5 per cent. salt; (2) salt may inhibit the activity of the amboceptor or complement or both, in the same way as it inhibits the antiseptic action of $HgCl_2$; and (3) the surface tension may play some part in the combinations of the active albuminoid (?) substances, amboceptor, complement, pellicle of red cell.

7. The albumins in serum to some extent inhibit hæmolysis, and hence better results are obtained by diluting.

8. 0·5 per cent. sodium chloride does not hæmolyse sheep's red blood corpuscles (when fresh).

9. Heated human serum contains active sheep's amboceptor (and does not hæmolyse).

The Method of Procedure.

A.—Collect samples of about ½ c.c. of blood from tuberculous patients, and also healthy people. Very little pressure should be employed when drawing the blood, as this tends to produce spontaneous hæmolysis of the human red cells. The blood should be allowed to clot, and may then be centrifuged, or put in an ice chest for 12 hours, so as to obtain the maximum quantity of serum. The serum should not be removed from the clot for at least six hours.

B.—An emulsion of tubercle bacilli in 1 per cent. salt should be prepared. This is made by very gently grinding the dry bacilli in Hayden's mortar, and gradually adding salt solution. The emulsion should be centrifuged, and the supernatant opalescent fluid employed.

C.—About 100 c.mm. of serum should be drawn off into a blood capsule, sealed, and heated in a bath at 56° C. for ten minutes.

D.—Prepare from glass tubing a series of small test-tubes 1½ inches long by ¼ inch. Place four strips of plasticine (a form of putty) on a small board, and affix on it four rows of tubes, A, B, C, D. To the tubes of the line A add 40 c.mm. of heated and 10 c.mm. of unheated serum from the same patient, and 150 c.mm. of 0·5 per cent. sodium chloride. To the tubes of the line B add 10 c.mm. of unheated serum and 190 c.mm. of 0·5 per cent. sodium chloride. To the tubes of the line C add 10 c.mm. of unheated serum, 10 c.mm. of tubercle emulsion, and 180 c.mm. of 0·5 per cent. sodium chloride. To the tubes of the line D add 40 c.mm. of heated and 10 c.mm. of unheated serum from the same patient, 10 c.mm. of tubercle emulsion, and 140 c.mm. of 0·5 per cent. sodium chloride. Shake the tubes to mix the ingredients, stopper them with a strip of plasticine, and incubate for two hours at 98° F.

E.—Centrifuge citrated sheep's blood (2 parts of 1 per cent. sodium citrate, 1 part sheep's blood); draw off the supernatant fluid, and add 1 per cent.[3] NaCl; centrifuge again; repeat the process three times. Finally, prepare from the deposited red cells a 1 in 10 dilution with 0·5 per cent. salt. After the two hours' incubation add 5 c.mm. of the 1 in 10 sheep's corpuscles to each tube. Controls of heated serum, salt, and tubercle emulsion should also be put up.

If the patient is tuberculous, there will be no hæmolysis in the tube of line D, but there will be hæmolysis in the corresponding tubes A and B.[4] The condition in C will depend upon the degree of immune bodies present. If the immunity is high, there will be no hæmolysis; if low, there will be hæmolysis. With normal sera hæmolysis occurs in D, more in C, and most in A and B, or all four may be equal.

Tuberculous patients who are suffering from fever and in whom the disease is advancing, may show hæmolysis in all four tubes, thus suggesting that the disease is progressing faster than the (antitoxin) immune-forming powers of the body. As the patient's health improves, no hæmolysis occurs in tube D and later none in C.

In a doubtful case four readings should be taken: before exercise, after exercise, one day after exercise, and two days after exercise. The exercise throws into the circulation an excess of toxin; this reduces the immunity, and hæmolysis occurs in tube D. Later there is a reaction, which increases the immunity, and now no hæmolysis occurs in D.

This system of testing serum not only gives a method of diagnosis in an obscure case, but also supplies a guide as to the immunising powers of the patient during therapeutic inoculation.

By putting up tubes containing—

1.	10 c.mm. unheated serum	
2.	Ditto	+ 10 c.mm. heated serum
3.	Ditto	+ 15 c.mm. ,,
4.	Ditto	+ 20 c.mm. ,,
5.	Ditto	+ 40 c.mm. ,,

an immunity index can be arrived at, and may be recorded thus—1, ½, ⅓, ¼, ⅛.

I have carried out this test with success with 20 tuberculous patients and 10 normal people. Also in a case of gonorrhœal arthritis, using the gonococcus in place of the tubercle bacillus.

As a rule, when the opsonic indices to tubercle are high, tuberculous patients show this test very well; when the opsonic index is low, the test is sometimes negative, but when the health improves, the test again becomes positive. This fixation of the complement test quite independently proves the value of the opsonic index as a means of diagnosis and an indication of progress. It also appears to show in a mixed infection which is the predominating organism. This latter point I cannot as yet state for certain, till my experience has been greater.

It will be seen that this test is on the lines of Flemming's modification of the modified Wassermann reaction, with the difference that the relation of the immune body to the complement is standardised in place of the antigen. It would, no doubt, also give a means of estimating the degree of reaction in the Wassermann test for syphilis.

Wassermann and Brück in 1906 failed to bring off this fixation test for tubercle; their procedure was different, and perhaps they failed to pay attention to the tonicity of the fluids employed.

It is too early to state what degree of reliance can be placed on the reaction, but as it has never failed in any of the tuberculous cases that I have tested, [nor given a positive result in a non-tuberculous case, I am tempted to publish the results.

Cases.—Normals tested with Tubercle Emulsion.

Patients.

1.—Female, aged 30. Synovitis right knee. Hæmolysis A, B, D, with tubercle. No hæmolysis D with gonococcus. Gonococcus opsonic index 2, reacting also to exercise. Repeated twice.

2.—Female, aged 17. Disease and sinus right ankle. Hæmolysis A and C; none in D with tubercle bacilli. Opsonic index 1. Repeated twice.

3.—Male, aged 21. Disease left ankle, three years' duration. No hæmolysis D and C. Hæmolysis A and B. Leg has since been amputated. Tuberculous disease.

4.—Female, aged 30. Polyarticular rheumatism. Opsonic index to tubercle fluctuated with exercise. Hæmolysis in all tubes (not tubercle). Repeated four times.

5.—Female, aged 16. Tubercle of lung. Tubercle bacilli found in sputum. Nov. 25th: Tubercle bacilli. Opsonic index 0·63. Hæmolysis A, B, C, D. 27th: Condition improved. No hæmolysis D. Dec. 12th: Condition further improved. No hæmolysis C and D.

6.—Male, aged 17. Cough, shortness of breath. Opsonic index tubercle low. Nov. 28th: Hæmolysis A, B, C, D. Temperature 101° F. 30th: Hæmolysis A, B, C, D, after breathing exercise. Dec. 6th: No hæmolysis C and D. Hæmolysis A. Condition greatly improved. Repeated twice.

7.—Male, aged 26. Tuberculous lungs, three years. Tubercle bacilli found in sputum. No hæmolysis C and D. Hæmolysis A and B. Repeated four times.

8.—Male, aged 26. Same as previous case.

9.—Male, aged 26. Tuberculous spine 20 years ago; at present quite fit. Trace of hæmolysis D. Marked hæmolysis A, B, C.

10.—Male, aged 13.—Tuberculous spine; lumbar abscess. No hæmolysis C and D. Hæmolysis A and B. Repeated.

11.—Female, aged 9. Tuberculous pleurisy, also tuberculous lung. 24 hours after tapping hæmolysis in all tubes (Nov. 28th). 29th: No hæmolysis D. Repeated twice.

12.—Female, aged 9. Tuberculous disease of spine, fingers, skin of face. No hæmolysis C and D. Hæmolysis A and B. Repeated twice.

13.—M——. Tuberculous disease of knee-joint. Opsonic index 1·34. Hæmolysis A. No hæmolysis D.

14.—I——. Early phthisis. Opsonic index 0·92. Hæmolysis A. No hæmolysis D.

15.—Male. Tuberculous glands in neck. Hæmolysis A. No hæmolysis D.

16.—Girl, aged 18. Tuberculous glands in neck; tubercle of spine of two months' duration. X ray photograph shows caries of lumbar vertebra. Hæmolysis A and B. No hæmolysis C and D.

[3] 1 per cent. is used to prevent hæmolysis during centrifuging.

[4] If no hæmolysis occurs in A, no conclusions can be drawn.

17.—Boy, aged 6. Tubercle of lung; continuous fever for two months. No hæmolysis C and D. Hæmolysis A and B.
18.—Female, aged 23. Syphilitic iritis. Wassermann reaction positive Tested with tubercle one week after treatment with "606." Hæmolysis in all tubes.
19.—Male, aged 23. Abscess of sole of foot; slight fever. Hæmolysis in all tubes.
20.—Male, aged 25. Old-standing empyema; no evidence of tubercle. Hæmolysis in all tubes.
21.—Male, aged 25. Sycosis. Treated with staphylococcus inoculation six months. Hæmolysis in all tubes with tubercle.
22.—Boy. Gland in neck. Pus aspirated. Cocci present. No evidence of tubercle. Hæmolysis in all tubes with tubercle.
23.—Boy. Old tuberculous disease of ankle, quite fit, and running about. Hæmolysis in all tubes with tubercle.
24. Female, aged 30. Rheumatoid arthritis. Pseudo-diphtheria bacillus isolated from cervix uteri, and inoculated with this bacillus for three months. Hæmolysis in all tubes with tubercle.
25. Female, aged 31. Gonorrhœal disease of wrist-joint. Hæmolysis in all tubes with tubercle.
26. Male, aged 45. Polyarthritis. Hæmolysis in all tubes with tubercle.

As a general rule, patients suffering from tubercle and inflammatory diseases other than tubercle give very marked hæmolysis with sheep's red cells, suggesting that in these diseases there is an abnormal quantity of complement produced. When serum is removed a few minutes after clotting takes place, and is mixed with sheep's corpuscles and 0·75 per cent. salt and incubated, hæmolysis occurs with 3 c.mm., but not with 1 and 2 c.mm. But when incubated for one hour at 98° F. in the presence of 0·75 per cent. salt previously to adding the corpuscles, no hæmolysis occurs with 6 c.mm.

Ealing.

THE CLINICAL ASPECTS OF "JUVENILE GENERAL PARALYSIS,"

WITH AN ACCOUNT OF A CASE TREATED WITH "606," AND OBSERVATIONS ON PROPHYLAXIS.

BY J. JOHNSTON ABRAHAM, M.D. DUB., F.R.C.S. ENG.,
LATE RESIDENT MEDICAL OFFICER, LONDON LOCK HOSPITAL FOR WOMEN AND CHILDREN, HARROW ROAD, W.

THE history of juvenile general paralysis bears a curious resemblance to that of many other diseases once considered rare, now generally recognised as of comparatively frequent occurrence. Its existence was unknown until 1877, when Clouston published a description (1)* of his first case in a boy, aged 16 years, under the name of "developmental general paralysis," and showed that it resembled, both clinically and pathologically, the form up to then considered exclusively confined to adult life. Two years later a second case was described by Turnbull in a child aged 12 years (2), and again two years later similar isolated examples by Nolan and Wiglesworth (3). It was in the same year that Regis recorded the first case on the continent (4). The condition was still considered very rare. Nevertheless, in 1895 Alzheimer had collected 40 cases, including 3 of his own (5), and in 1898 Thiry (6) had raised the number of known cases to 69. In 1900 Mott (7) published an elaborate analysis of 22 cases, collected in three years, from the London County Asylums alone, in 1908 he had raised the number of cases observed by him to 40 (8), and in 1910 to 60 (9). In the last 10 years cases have been recorded with increasing frequency from many other countries, till now there must be several hundreds in the literature, and it is not surprising to find that Fennell (10), as the result of his observations at Darenth, came to the conclusion that 5 per cent. of imbecile children were congenital general paralytics.

It will thus be seen that either the condition is becoming more frequent or else is being more readily diagnosed. Probably both suppositions are correct, yet undoubtedly, although the alienist is now constantly on the lookout for such cases, the medical profession as a whole has not yet grasped either their importance or their frequency; and, considering their invariably fatal termination, sufficient stress has not been laid on the paramount importance of treating every child, of known syphilitic parents, giving a positive Wassermann, whether it shows signs of congenital syphilis or not, as carefully as if it were an adult with definite symptoms of the disease; for it is a peculiarity of juvenile general paralysis that many of these children show absolutely none of the stigmata of congenital lues, though nearly all give a positive Wassermann.

* The parenthetical figures occurring throughout the article refer to the bibliography at the end.

It seems scarcely necessary now to labour the point of the close connexion between general paralysis and syphilis. Gowers and Ferrier always maintained the relationship with regard to tabes. Mott has shown (11) that tabes and general paralysis are expressions with connecting links of the late results of syphilis on the central nervous system. Fournier (12), as the result of his vast experience, positively affirmed that tabes and general paralysis were so alike in their etiology that they might be included under a common term, "parasyphilis." Krafft-Ebing (13) stated that general paralysis was the result of "civilisation and syphilisation," and after inoculating nine individuals suffering from general paralysis, who showed no signs of syphilis, with the virus of a hard chancre, waiting for 80 days, and finding then that none of them showed any symptoms, came to the conclusion that they were immune because they already had the disease. Finally, the fact that general paralytics give a positive Wassermann reaction in practically 100 per cent. of cases (14, 15, 16, 17) conclusively proves that if a positive Wassermann means syphilis, and it is a fact that the reaction is constant in the cerebro-spinal fluid or serum of general paralytics, then it amounts almost to a demonstration that "no syphilis means no general paralysis." The only other view with any pretence to scientific support as to etiology is that of Ford-Robertson (18), who maintains that the organism isolated by himself and MacRae from the cerebro-spinal fluid of general paralytics, and named by them the "bacillus paralyticans," is the causal factor of the disease. O'Brien (19) has published a paper in support of the view, but other competent investigators, Marie (20), Chandler (21), Thomson (22), and Williamson (23), have either not been able to find the organism, or have found it as often in controls as in general paralytics, or have found that it exists as a common organism in the throat and skin in normal individuals, and cannot be considered the causal factor of the disease, or more than a secondary infection in general paralytics. Most alienists have therefore come to the conclusion that syphilis is a necessary precursor of the disease. [Anyone interested will find the views for and against syphilis discussed at length in Nonne.[1]] That syphilis is not the exciting cause seems, however, evident, since only from 3 to 5 per cent. of syphilitics develop tabes or general paralysis (Mott). In adults it is generally stated that alcoholic and sexual excess is responsible for tipping the scale, but in children excess "in baccho et venere" can generally be excluded, and so the stress of puberty is usually considered the exciting cause, the ordinary age of onset being from 13 to 15 years, though cases as early as 8 years of age and as late as 23 years are recorded. The fact, however, that as a rule the reproductive organs are of the infantile type seems to weaken the assumption. One of McDowall's cases[2] was, notwithstanding, sexually well developed. Mott (24) mentions one case where a fall from a van seems to have been the exciting cause, and Collin (25) one of a boy who developed symptoms after an injured finger had been removed.

As to sex, in contradistinction to the adult type where 80 per cent. of the cases are male, in the juvenile type the sexes are almost equally divided, with perhaps a slight preponderance amongst females.

Two mental and two physical types are found amongst these children. Mentally they may be defective from birth, ranging from idiots to high-grade imbeciles, or they may be bright and highly intelligent until the commencement of their illness. Physically they may show all the stigmata of congenital syphilis, or, as has been pointed out by Mott (26), may have absolutely no signs of syphilis whatever, whereas brother and sisters, not suffering from general paralysis, often have well-marked signs, as though the disease had spent itself on the cutaneous and bone lesions, and allowed the central nervous system to escape. It would seem, then, that it is more often in the mild or cryptic forms, those least likely to have had an adequate course of treatment, that the disease is more likely to show itself, and it is probable if it were not for the number of abortions, miscarriages, still-births, and deaths in early infancy, directly attributable to syphilis, the number of cases of juvenile general paralysis would be very much greater than has been found to be the case."

Assuming, then, that any congenital syphilitic may be a

[1] Syphilis und Nervensystem. Berlin: S. Krager, 1909.
[2] Journal of Mental Science, Jnuaray, 1908, p. 112.

potential juvenile general paralytic, it becomes a vastly important matter, as pointed out by McDowall (27), to determine at what age we can safely assume that the children of known syphilitic parents are free from the risk of developing general paralysis. The average age of onset from Mott's statistics works out at 17, but he has had two cases occurring at the age of 23, and another at the same age is recorded by Burzio (28). Judging from statistics, then, the risk of a congenital syphilitic developing general paralysis after 25 years of age is very small, unless, indeed, as Mott suggests, it is possible for the adult type to occur as the result of the congenital as well as the acquired variety (29).

Turning now to individual details, it will perhaps be more interesting to describe the symptoms in the case recently under my care, comparing and contrasting them at the same time with those of the recorded cases and with the adult type.

The patient was a boy who was admitted to the East Sussex County Asylum as an imbecile. He was a good-looking, bright-eyed lad of apparently 8 years of age, though he was in reality 13, could answer simple questions, write his name rather badly, but could not read or recognise colours. He was sent to the school for defective children attached to the asylum, proved rather dull, but was cheerful and well-behaved, and appeared to be in good health. In this state he remained for three years. In the interval his mother was admitted to the asylum as a general paralytic, an exceedingly uncommon coincidence, for though it is not rare for father and son each to develop general paralysis, it is extremely rare to find mother and son suffering from this disease in the same institution at the same time. It was the first intimation we had that the boy had a syphilitic heredity, as no details of his family history had been elicited when he was admitted, and he was free from all signs of syphilis, except two rounded smooth scars, one on either buttock, which were probably not syphilitic, as condylomata, which are quite common in that region in congenital syphilis, do not leave scars unless as the results of syphilo-sepsis.[3] After his mother's admission, however, he was kept under observation, but nothing developed until he was 16 years of age. He was then a bright, smiling high-grade imbecile looking about 10 years of age, able to run about and make himself useful, with a very limited but distinct vocabulary, and no apparent delusions.

On Sept. 21st, 1910, the boy suddenly developed a temperature of 102° F., and had retention of urine. Nothing was found in the chest or abdomen to account for the temperature, which subsided to normal in four days, during which time the patient had to be catheterised daily, a 24-hour specimen, amounting to 18 ounces, giving a specific gravity of 1032, containing 2·8 per cent. urea, no albumin, but a partial reduction of Fehling on testing for sugar. He lay smiling in bed, turned on his right side, with his knees drawn up, passively resisting attempts to straighten them. His bodily condition was fair, but the arms and legs were thin, and the genitals of the infantile type so commonly associated with the disease. The bowels only acted after enemata. The pupils were unequal, small, eccentric, oval, and sluggish to light. Accommodation could not be satisfactorily tested. There was no nystagmus, a rare condition which occurred only once in Mott's cases,[4] and no external ophthalmoplegia, a condition not uncommon in cerebral syphilis, but occurring again only once in Mott's cases (paralysis of the external rectus in Case 6). Both knee-jerks were exaggerated, as is usual in the disease, though in later stages it is not uncommon to find them absent on one or both sides. He never spoke, and had to be spoon-fed.

On Sept. 25th the patient was reported to have had a "seizure" in the night. During the following day he had eight typical epileptiform attacks. There was no cry, but he lay in bed with flushed, twitching face, his forehead and cheeks covered with large beads of perspiration. There was conjugate deviation of head, neck, and eyes to the right. The pupils were dilated and fixed. His right arm and leg twitched in unison with his grimacing face. When no attack was on there was a constant coarse tremor of the lips, and a curious, apparently unconscious, smacking as if after pleasant food. The tongue was protruded in a jerky manner, curled up at the tip, but was not markedly tremulous. Attacks occurred with diminishing frequency during the following week, and then ceased. Afterwards a crop of herpetic vesicles appeared on the lower lip. During the attacks loss of control of the bladder or rectum did not occur. Distinct paresis of the right face, the right arm, and the right leg followed the attacks, the superficial reflexes were very active, but there was no Babinski. Ankle-clonus was easily elicited on both sides (a rather uncommon occurrence), the knee-jerks were markedly exaggerated, wrist and triceps jerk well marked, but there was no jaw-jerk. Once or twice he vomited during an attack, a common occurrence in the "seizures" of general paralysis. There was no headache, judging from subjective signs. Under the action of homatropine the pupils dilated irregularly, showing pericyclic outlines. Examination showed optic atrophy, most marked in the right disc, but no chorio-retinitis. Watson (30) in 12 post-mortem examinations in such cases found optic atrophy in four, but this appears to be a much greater proportion than is found clinically. Chorio-retinitis, on the other hand, is not uncommon.

Examination of the patient's serum showed a well-marked Wassermann reaction, 0·25 cubic centimetre of complement being fixed, whereas 0·1 cubic centimetre is usually required for diagnostic purposes. According to Nonne (31), a general paralytic should give the following reactions: (1) lymphocytosis in the cerebro-spinal fluid; (2) the globulin reaction; (3) Wassermann in the "fluid"; and (4) Wassermann in the serum. In a previous paper (32) he states, however, that the cerebro-spinal fluid may give a negative Wassermann in juvenile general paralysis, just as it does in 30 per cent. of the adult type.

On Oct. 2nd the facial palsy was seen to be improving, the brows corrugated naturally, the eyelids closed, but the lower half of the face remained as before. During the next fortnight the paresis of the right arm and leg improved till the grip was equal on both sides. The reflexes, however, were as active as during the "attacks," and both upper and lower limbs were so paretic that he could not sit up in bed, or attempt to feed himself. He was able, however, to shake hands, smile frequently, and to speak a few words very indistinctly. Urination was normal again.

The patient showed no symptoms of any delusions, as was to be expected in an imbecile. Indeed, the usual grandiose delusions of wealth, ambition, sexual power, or the inverted grandiose depression so equally characteristic of the adult type, are not to be expected in the juvenile form, even when attacking a previously normally intelle tual child, because, as pointed out by Mott (8), "until puberty these passions have not formed a part of the experience of associative memory, have not been deeply organised in the brain, and so when the brain begins to decay, and the mind is shed, there are none of these passions present to rise uncontrolled into consciousness in pathological magnitude." This has been the general experience of most observers (33), but nevertheless there have been exceptions. One of Mott's cases thought he was a Member of Parliament, which, in the pauper class, may be considered an "idea of grandeur," and Kleineberger (34) records five cases with "childish ideas of grandeur."

During the month of October the patient's condition remained unchanged, except that at times he lost control of his bladder and rectum, evacuating unconsciously; and so, in spite of the fact that optic atrophy was present, it was decided to try the effects of "606" on him. Accordingly, on Oct. 30th. 0·3 gramme in solution was injected into the buttocks. No pain apparently was present after the injection, but the patient did not sleep as usual that night nor all the next day, and he frequently wrinkled his brow and put his left hand to his head in a puzzled manner. Eventually after 36 hours' sleeplessness he was given one-sixth of a grain of morphia, hypodermically, with good effect. After that he was able to sleep naturally without drugs.

The peculiar erythematous rash known as the "Jarisch-Herxheimer reaction" was not present in this case, a little local redness present at the seat of injection passing off in a few days. The temperature rose to 100° F. on the day after the injection, and continued above normal for six days. On Nov. 8th the patient developed atony of the bladder, associated with marked constipation, and had to be catheterised for two days. Such symptoms cannot, however, be ascribed to the drug, as he had had similar attacks twice before in the previous month.

[3] The absence of signs of syphilis is not uncommon. Of Mott's 7 cases, 15 showed signs of syphilis, 9 did not. (Archives of Neurology, vol. i.).

[4] Archives of Neurology, vol. i., p. 278.

Re-examined on Nov. 26th, four weeks after the injection, the patient's condition was as follows. Speech was more easily elicited, but was quite imbecile in character. Articulation was like that of a cleft-palate case. The pupils were unequal, the left reacting feebly to light under strong electric illumination, the right inactive. Reaction to accommodation could not be satisfactorily ascertained. The superficial reflexes were still exaggerated. Elbow-jerk, wrist-jerk, knee-jerk, and ankle-clonus well-marked and easily elicited. The bodily condition showed continued wasting since the injection. There was no difference in the fundus. Loss of control of bladder and rectum was present, and the patient was unable to stand or sit up.

It will thus be seen that there was practically no improvement, and this is in keeping with the vast majority of clinical reports recorded in the adult type and in tabes. At the outset Ehrlich cautioned against the use of "606" in degenerative changes, and in a recent communication to Sachs stated that there had been 12 deaths in advanced cerebral and spinal disease after its use (35). In cerebral syphilis, however, Neisser states that paralysis and pains disappear like magic, and advises that it may be tried in early tabes and general paralysis, questioning, however, if it is safe when optic atrophy is present. From experiments on animals it has been found that "606" is not injurious to the normal eye, but in the human subject it is stated that transitory blindness may occur. Speithoff and Michaelis had a tabetic who 50 hours after an injection of 0·6 gramme was seized with temporary blindness for several minutes, and another who, eight weeks after an injection of 0·45 gramme, developed sudden ptosis of one lid and blindness lasting ten minutes. Nothing was found ophthalmologically (36). Glück treated two cases of paresis and one of optic atrophy without result (37). Fordyce[5] treated nine tabetics with little result, and one case of cerebral syphilis with wonderful success. Dr. Ivy Mackenzie reports that of 16 general paralytics four were undoubtedly benefited (38). Michaelis in one of his general paralytics had a remission lasting two months. In 12 paralytics treated by Meyer there was no lasting result. The Wassermann reaction after treatment in these cases of Meyer was very interesting; four gave a negative reaction, four a diminution, and four were uninfluenced (39). In this connexion it is interesting to note the extreme difficulty of influencing the Wassermann reaction by treatment in congenital syphilis. In the London Lock Hospital for Women and Children we found that even after two years' in-patient treatment by inunction children still gave an active Wassermann reaction; and McDonagh states that congenital syphilis, irrespectively of treatment, tends to give a positive Wassermann reaction throughout life (40). This statement, though there are strong reasons for believing that it is in the main correct, is probably not absolutely without exception, as the term "congenital syphilis" is at present loosely used to include cases both of infection before birth, in which the child is born dead, or if alive comes into the world with well-marked signs of syphilis, and cases of infection from the placental blood, occurring during the period of delivery, and manifesting themselves some three or four weeks after birth.

Reverting again to the main subject, it will be seen from the cases quoted above that in syphilitic and parasyphilitic affections of the nervous system hopes of success may be entertained in cerebral syphilis, and that amelioration of symptoms in some tabetics and remissions in some general paralytics may follow the use of the drug. To anyone, however, acquainted with the frequent remissions, and even sometimes complete cessation of ataxic and mental symptoms, for a time in tabetics and general paralytics without treatment, the evidence that such improvement is due, in the cases quoted above, to the use of "606" is not convincing, and the necessity of early and systematic treatment to prevent these late manifestations becomes increasingly urgent. In Wassermann's reaction we apparently have a means of discovering latent congenital syphilis in the children of known syphilitics, and these are the cases that seem particularly liable to develop juvenile general paralysis. Considering, then, the apparent hopelessness of checking the malady by even the latest form of treatment, and the known fact that mercury has been proved time and again to be equally useless, it is imperative that such children should be given the very best possible chance at the earliest possible opportunity; and the mere fact that treatment has a very dubious effect on the character of the Wassermann reaction, instead of suggesting to us the impossibility of curing congenital syphilis, should stimulate us, on the contrary, to continue treatment, possibly for years, instead of, as is so frequently the case, stopping treatment as soon as the early manifestations during the first year of life subside.

Ehlers of Copenhagen reports a death five days after the injection of 0·5 gramme of "606" in a general paralytic.[6] The patient was a man, aged 40 years, who had developed syphilis 11 years previously and had been insufficiently treated. In April, 1908, he had an apoplectiform seizure. In August of the same year he first began to show signs of general paralysis (dementia paralytica). In July, 1910, he had a second seizure. On August 25th he was injected in the interscapular region subcutaneously with a neutral suspension after the manner of Wechselmann. His symptoms were those of poisoning; there was tremor, shivering, sweating, and progressive loss of strength. His temperature rose to 103·6° F. (39·8° C.). He died from paralysis of the heart. A post-mortem examination showed all the organs to be healthy except the heart, in which there was acute parenchymatous degeneration. Details of the microscopic examination of the nervous system have not yet been published.

I beg to acknowledge my indebtedness to Dr. F. R. P. Taylor for permission to record the case, to Dr. C. H. Fennell for much help in valuable details, to Mr. H. W. Bayly of the Lock Hospital for the Wassermann results, and to Dr. Otto Grünbaum for the use of the "606."

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION.

British Health Resorts for Foreign Invalids.

A MEETING of this section was held on Dec. 14th, Dr. T. F. GARDNER, the President, being in the chair.

Dr. NEVILLE T. WOOD read a paper on British Health Resorts for Foreign Invalids. He said: Whereas a large percentage of the patients at the better known continental spas hail from Great Britain, the number of foreign invalids sent to British health resorts is quite insignificant. The reason for this state of things is that the policy of British municipalities exhausts itself in the endeavour to keep Britons from foreign countries rather than to bring the foreigner to ours, and in addition to that no serious

attempt has been made by the profession in England to inform their foreign colleagues that there exist in our island spas and climatic stations of the highest rank. Continental spas should not be regarded as competing with British spas, nor British with continental, the indications for the two groups differing so widely that they are complementary to each other. Speaking generally, the categories of foreign invalids for which our spas are typically suitable include those who thrive in a relatively cool climate and are able to walk well, those who in association with complete change derive benefit from baths which are neither very hot nor taken in close succession, and those whose maladies are held to be tributary to the waters we possess—that is to say, the muriated, sulphuretted, iron indifferent, earthy, and alkaline sulphated. A comprehensive view of British spas from an international standpoint is that, whereas for Britons they are mineral water stations with climatic advantages, for foreigners they are climatic stations with the advantage of mineral waters. It has been objected that our spas are intolerably dull, but there are very many on the continent visited annually by thousands of invalids which are not in any way more lively. Excessive rainfall has been urged against all of our resorts, but on the European mainland, too, it is not uncommon for a whole season to be spoilt by persistent downpour of rain; and, as a matter of fact, in summer less rain falls in the eastern division of England than at some of the stations of Western Europe. Our seaside resorts possess for foreigners advantages which, if not so well defined, are even wider in range. Foreigners are accustomed to and demand higher temperatures in summer than are agreeable to English people. This difficulty may be met by sending continental patients to the warmer of our coast stations. We have, in addition, inland climatic stations where the air, though bracing, is not devoid of sedative qualities. Among such stations may be mentioned Hindhead, Church Stretton, Crowborough, Okehampton, and Ben Rhydding. When the inhabitants of Central Europe become as well aware of the advantages of British health resorts as we are of the indications for theirs, there will be a free interchange of invalids instead of as now a movement in only one direction—and that away from our shores. In order to accomplish this purpose a book is now under consideration with descriptive monographs written and the whole collated by whatever chapters may appear to be necessary.

The PRESIDENT, Mr. E. SOLLY, Dr. F. BAGSHAWE, Dr. R. FORTESCUE FOX, Dr. A. MANTLE, Dr. F. H. HUMPHRIS, and Dr. J. LIDDELL took part in the discussion which followed, and Dr. WOOD replied.

EDINBURGH OBSTETRICAL SOCIETY.

The Modern Treatment of Contracted Pelvis.—Lantern Demonstration.

A MEETING of this society was held on Dec. 14th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

Sir JOHN HALLIDAY CROOM read a paper on Modern Treatment of Contracted Pelvis. At the outset he referred to the diminution of sepsis in hospital practice, which permitted many interferences now which were impossible in the olden days, and he further referred to the fact that sepsis still continued in private practice. He thought it was useless to discuss the methods of dealing with the narrow pelvis until practitioners recognised the fact that a careful and accurate measurement of the pelvis in every primiparous woman, and in every multiparous woman with a bad obstetrical history, must be carried out. He referred to the fact that in midwifery, as well as in general medicine, preventive treatment was more important, instancing the successful prophylaxis of obstetric complications in the Pre-Maternity Home in Edinburgh. He divided narrow pelvis, for all practical purposes, into three categories. First, those below 3 inches; second, those above 3¼; and third, those between 3 and 3¼. With the first variety there was no difficulty in dealing, because in them the only treatment, when diagnosed before labour, was Cæsarean section, which, of all abdominal operations, was by far the most satisfactory. He then dealt with the question of such cases being seen late in labour, and with the field of craniotomy, which he pointed out as getting more and more circumscribed every day. He recommended a more general use of maternity homes and nursing homes for the treatment of all obstetric operations. Sir John Halliday Croom pointed out that with the disappearance, in hospitals at least, of puerperal septicæmia, confidence in the forces of nature had returned, and labour in a narrow pelvis was allowed now to complete itself spontaneously in a great proportion of cases. This method of treatment was strikingly successful both for the mother and child. He believed that spontaneous delivery might be looked for in cases with a conjugate of slightly under 3½ inches in flat pelves and 3¾ inches in generally contracted pelves. The Walcher position should never be omitted in these cases as an aid to the fixation of the head. The duration of the second stage of labour was to be limited only by the condition of the mother and child. The great difficulty centred round the quarter of an inch between 3 and 3¼ inches. In that small area there was a choice of treatment. If the condition were recognised early, there was the option of inducing premature labour; if not seen until term, there was the choice of attempting to deliver by forceps or by some operation for enlarging the pelvis. The position of the operation of the induction of premature labour was that it was perfectly safe for the mother, but unfortunately was accompanied by a very considerable infantile mortality. In regard to high forceps operations in narrow pelvis, the mortality and morbidity to the mother were unquestionable. This was absolutely proved by statistics. The fœtal mortality in these cases ran between 20 and 40 per cent. He then referred to the development of the operations for the enlargement of the pelvis. These operations were not uniformly safe for the children, and were not unassociated with considerable risk to the mother. The cases in which these operations were useful were those of moderate contractions in which, after ample time had been given for the head to enter the brim, it still remained unengaged. There pubiotomy might be expected to be followed by spontaneous delivery, but if necessary, and particularly if the child's life were endangered, might be justifiably supplemented by forceps delivery. He thought that no high forceps operation should be seriously undertaken unless the operator was prepared to perform one of these cutting operations if necessary.

Dr. J. M. MUNRO KERR (Glasgow) alluded to the tendency in recent years to leave difficult cases to nature. Yet he remembered how Dr. Milne Murray extolled highly the use of axis-traction in high forceps cases and how he could accomplish delivery in pelves with a conjugate of 2⅞ inches. But in high forceps difficult cases the fœtal mortality was about 50 per cent. If these cases were given plenty of time, from 50 to 60 per cent. were delivered spontaneously. In such cases one should estimate the size of the head and pelvis, and give plenty of time for nature to mould the head; if that failed forceps should be applied. If fair traction was not sufficient one should never resort to brute force to pull the head through, but then perform pubiotomy. In obstetrics care should be taken not to be led by fashions. Even now pubiotomy was being decried by previous supporters.

Dr. J. W. BALLANTYNE advocated the education of public opinion as to the necessity for careful examination of the pregnant woman to ascertain the presence of such conditions as albuminuria and pelvic deformity. Obstetrical homes were much needed, and also an obstetrical bed readily adaptable to the Walcher position and for the performance of operations.

Dr. J. HAIG FERGUSON alluded to the complete change in their views as regards the application of the high forceps, considering it unjustifiable to apply them if the head was free above the brim. It was better to give plenty of time for moulding of the head to take place, at least in slighter degree, before applying the forceps. In private practice the fœtal mortality was not nearly so great as in hospital practice.

Dr. W. FORDYCE thought they were losing sight of the value of the old operation of turning; it gave the advantage of engaging the narrow wedge of the head in the conjugate, and this could be assisted greatly by the pressure of the hand directly on the head through the abdominal walls. Sir Halliday Croom had given exact measurements of the conjugate in his paper, but he (the speaker) had found it exceedingly difficult exactly to estimate the true conjugate. The diagonal conjugate was a help, and consideration must also be given to the position of the head.

The PRESIDENT said he thought the maternal mortality given by Sir Halliday Croom was impossible in experienced

hands; he had never once seen a woman die as a result of the application of high forceps. Much was to be gained by patient waiting on nature's attempts to mould the head. It was extremely difficult to measure the pelvis, estimate the size of the head, and the probable amount of moulding it would undergo. To discard forceps was a swing of the pendulum in the opposite direction.

Dr. JAMES RITCHIE and Dr. MICHAEL DEWAR also took part in the discussion.

Sir JOHN HALLIDAY CROOM, in his reply, mentioned that he considered forceps one of the best instruments, most excellent in their place, when the head was engaged in the brim or in the pelvic cavity.

Dr. JAMES YOUNG gave a lantern demonstration on the Mode of Action of the Fœtal Structures on the Maternal Tissues and the Function of the Decidua. He referred to the importance of a clear appreciation of the structure of the uterine mucosa in order to understand the changes during pregnancy. He had already pointed out that the stroma throughout its entire extent was a soft, mobile, protoplasmic mass imperfectly differentiated into cellular elements. As he had also pointed out, the fluid and blood escape from the vessels during menstruation was due to tissue change which led to an active dragging out of the blood elements from the vessels—the structural peculiarity of the stroma allowed of an opening-out of the vessel walls and a displacement of the stroma to the greatest advantage. Menstruation was not a congestive process. Dr. Young pointed out that the changes induced by the chorionic epithelium in the pregnant tube, chorion-epithelioma, &c., proved that there was liberated from the chorionic cells a bio-chemical material that spread into the surrounding tissues, extending its sphere of action more and more with the duration of growth. This substance altered the maternal tissues in such a way as to lead to an active imbibition of the blood fluid by the tissues, hence the widespread and uncontrolled œdema. Later it led to a dragging of the red corpuscles from the vessels—i.e., after the vessel walls were teased out. This was the cause of the opening up of the maternal vessels which occurred in these conditions; it was not due to a mechanical liberation of the contents from vessels, the walls of which had been eroded by the advancing chorionic epithelium. The tissue changes were due to an alteration in the protoplasmic colloids, with an increase in their affinity for fluid. In the case of the endothelial and connective-tissue elements this was manifested by a distinct intracellular collection of fluid. The same changes were present in the muscle elements, but here there occurred in the abnormal sites a speedy disintegration and solution. The result of these changes in the proximity of the fœtal elements was seen in a wholesale passage of the blood through the tissues towards the chorionic epithelium. The new vessel formation and the sinuses which developed were due to the same tissue changes. Dr. Young showed vessels from the decidua of two early human ova, which revealed the existence of the same cause of the blood escape. One of these ova was approximately 14–15 days old. In the pregnant tube the only regions where the irregular and uncontrolled œdema and hæmorrhage were prevented were where a decidual change had occurred, and it was clear that, without it, the uterine mucosa would be torn up from fundus to internal os as successive levels came under the influence of the chorionic substances. The decidual membrane localised the changes to the proximity of the ovum. —Dr. B. P. WATSON, Dr. FORDYCE, Dr. HAIG FERGUSON, and Dr. J. LOCHHEAD discussed the subject, and Dr. YOUNG replied.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Dec. 20th at the Children's Hospital, Gartside-street. Mr. J. Howson Ray, the President, being in the chair.—Dr. H. A. G. Brooke and Mr. L. Savatard showed cases illustrating the dermatological affections of Tertiary Syphilis, a case of Molluscum Contagiosum, and a case of Primary Lupus Vulgaris in a youth.—Dr. J. G. Clegg showed an interesting case of Traumatic Vertical Hemiopia of the Right Eye. A short time before being seen the patient had received a blow on the right side of the nose, and the ophthalmoscope readily showed a hæmorrhage into the sheath of the right optic nerve.—Dr. N. C. Haring demonstrated the uses of the Pharyngoscope.—Dr. C. C. Heywood showed a case of Muscular Rigidity in an infant aged 18 months, and a case of Intention Tremor in a boy aged 13 years.—The President showed several children with Affections of the Hip-joint, with X ray photographs of each, and demonstrated the diagnostic points of difference between coxa valga, coxa vara, tuberculous hip disease, and tuberculous disease of the great trochanter. He also showed a case, on which he had operated recently, of extensive Cleft Palate and Hare-lip.—Mr. H. H. Rayner showed two cases, undergoing fixation treatment, of Congenital Dislocation of the Hip-joint, with X ray photographs of these.—Dr. J. A. K. Renshaw showed cases of Tuberculous Laryngitis among others.—Mr. P. R. Wrigley showed a case of Cerebellar Abscess and one of Sarcoma of the Left Frontal Bone, both in young girls.

Reviews and Notices of Books.

International Clinics. Edited by HENRY W. CATTELL, A.M., M.D., Philadelphia, U.S.A. Vol. III., Twentieth series. 1910. London and Philadelphia: J. B. Lippincott Company. Pp. 311.

THIS volume opens with an interesting contribution to the study of the ideographic cerebral centre, illustrated by a case of ideographic aphasia by Dr. H. V. Würdemann. This is followed by an article by Dr. Nathan P. Levin on Ehrlich's Diazo Reaction in Chronic Tuberculosis. This reaction, as is well known now, is not so absolutely diagnostic of enteric fever as its discoverer first thought. Although it is of almost constant occurrence in this disease, it has occasionally been present in a number of other affections, both acute and chronic, and of these it more especially occurs in some of the acute and chronic forms of tuberculosis. Dr. Levin, as a result of his inquiry into the latter aspect of the value of the reaction, states that it is very rare in the early stages of phthisis; that it does occur in a good proportion of the advanced cases, but not in all of them; and, lastly, that it is a bad prognostic omen, as, of course, follows from its occurring in these advanced cases. In his remarks on the treatment of pneumonia Dr. Joseph H. Lopez emphasises the value of the "hot jacket" over the messy, old-fashioned linseed poultice, which has to be so frequently changed, necessitating the patient to unnecessary exposure and discomfort. He gives us various useful formulæ, including, we are glad to notice, one containing strychnine, which should be given without waiting for the profound systemic depression to be developed. He does not mention the good effect of another very valuable drug, albeit also an old-fashioned one—namely, antimony. Dr. C. K. Austen writes on autoserotherapy, instancing cases where it gave good results in pleurisy, tuberculous and otherwise, and finding it efficacious in the majority of cases. It has also been tried with good effect in cases of ascites from cirrhosis of the liver.

An excellent contribution is by Dr. L. Howard Russell on Uncinariasis. He summarises the various signs of the disease, showing how vast districts of South America are infected by it. As regards the blood examination, that for the hæmoglobin is the most important, as nearly all the cases cited by Dr. Ashford and Dr. King show diminution of this constituent, whilst the most important and characteristic sign in the differential count is the eosinophilia. Nearly all the cases showed this: it is greater in the acute than in the chronic cases, and its decrease under treatment is a good prognostic sign. The red cells are usually reduced; in one case they were as low as 904,000. The changes in the stools, skin (which is dry and harsh), nervous, circulatory and digestive systems, are all portrayed, and finally the patient is shown to have been always undeveloped and to exhibit a peculiar apathy. With regard to the examination of the stools, the author lays great stress on the quick examination of the fæces under the microscope with a low

power. As regards treatment, thymol gives the best results, and if this be ordered, oil or alcohol should not be given at or near the same time that this drug is administered. The thymol should be repeated until the hæmoglobin rises. The dose is 30 grains. With reference to the mode of infection, the steps are as follows: the worm deposits its eggs in the intestine; these, however, are not hatched here, but mature when they, mixed with the fæces, are deposited in a fit soil. The entrance into the body occurs first through the skin, and, secondly, by swallowing. The anæmia is caused chiefly by the presence of some toxin, and not by the mere bleeding caused by the worm. The article is illustrated by some excellent plates.

Dr. Milton K. Meyers, in writing on hydrophobia, gives an excellent description of the bodies discovered by Negri in 1903. In his remarks on its incubation he urges that too much reliance must not be placed on those cases in which the disease developed years after the bite. There is, however, one well-authenticated case in India in which an officer died two years after the bite. He was the *last* person bitten with some others; these others underwent Pasteur's treatment, whereas he did not.

One of the best articles in this volume is by Dr. Daniel L. Hoyt, who discourses on what vivisection has done for medicine, both in treatment and diagnosis. By its means we have learned how to cure cretinism, how to relieve many cases of exophthalmic goitre. Lord Lister clenched the good effect of carbolic acid by an experiment on a horse, and this experiment marked the benefit of his antiseptic system, by which he has established himself without gainsay as the greatest benefactor to the human race that the world has ever produced.

Space only permits us to notice a few of the articles in this work, but all will repay perusal.

Portfolio of Dermochromes. By Professor JACOBI of Freiburg. English adaptation of the text by J. J. PRINGLE, M.B. Edin., F.R.C.P. Lond. Third and enlarged edition. In three volumes. With 132 plates, 243 coloured and 2 black-and-white illustrations, and 12 photomicrographs of parasitic fungi. London: Rebman, Limited. 1910. Price, full bound, £4 14*s.* 6*d.* net; half bound, £4 6*s.* net.

THE first English adaptation of Professor Jacobi's Dermochromes appeared in 1903 in two volumes, and these were so successful that a supplement was published in 1906. Dr. Pringle states in the preface to the edition of 1910 that it contains practically all the old plates and text of the old editions and the supplement, rearranged and enlarged. Ten entirely new plates have been added, and 12 photomicrographs of the commoner parasitic fungi. The latter, he points out, should prove useful to English-speaking countries, as the diseases caused by these fungi are unduly prevalent in Britain and her colonies.

We are not surprised to learn that a new edition has been called for so soon. The volumes are of use not only to dermatologists but to the profession at large, and to teachers and students. The simple and every-day diseases, as well as the rare conditions, are here illustrated, with a perfection of colouring and a detailed and life-like representation which is usually looked for in vain in illustrations of skin diseases. Especially useful to the student are the faithful portraits of the various stages and phases of the protean manifestations of syphilis. If we may single out any plates in a work showing so uniformly high a standard throughout, we would mention as of special merit those portraying psoriasis, lupus erythematosus, lupus vulgaris, the circinate form of pityriasis rosea, and tinea affecting the smooth skin. Darier's disease would have been clearer if a smaller area had been represented on the same size of plate, and the pictures of sclerodema are not very convincing. The characteristic purple infiltration of one stage of mycosis fungoides is not shown; and the early stage exhibited would not give much assistance in a difficult diagnosis. The photomicrographs are somewhat indistinct; most would only assist those who already had some experience in the diagnosis of the different fungi.

The letterpress is short and to the point, and adds greatly to the usefulness of such an atlas for the general practitioner. We cordially welcome the work, which is at once so truthful and so artistic, and we anticipate that it will have a wide circulation.

LIBRARY TABLE.

Surgical Diagnosis. By DANIEL N. EISENDRATH, A.B., M.D., Professor of Surgery in the Medical Department of the University of Illinois (College of Physicians and Surgeons); Attending Surgeon to the Michael Reese and Cook County Hospitals, Chicago. Second edition, thoroughly revised and enlarged, with 574 original illustrations, 25 of them in colours. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 885. Price 28*s.* net.—The importance of diagnosis can hardly be over-estimated. Anything which assists in improving the student's power in recognising different morbid conditions deserves a welcome, and we know no work which is better calculated than this to afford real assistance to the student in diagnosing a disease. The large number of illustrations present should assist materially the student in appreciating the points of difference between one disease and another. The majority of these illustrations are reproductions from photographs and show very clearly what is intended. We think that any student or practitioner who makes use of the book to improve his diagnostic powers will not repent of the trouble.

Houses, Villas, Cottages, and Bungalows for Britishers and Americans Abroad. By GEORGE GORDON SAMSON. London: Crosby Lockwood and Son. 1910. Pp. xvi.-131. Price 3*s.* 6*d.* net.—This little book shows plans for several houses, varying in cost of construction from £130 to £1400, ingeniously planned to be adaptable to several styles of external treatment. Many of its suggestions are particularly suitable for those who desire a *pied-à-terre* in the Riviera, Algeria, and other health resorts, in which not only the initial cost but the working expense also shall be reduced to a minimum. Its subject matter will also interest medical practitioners and others—it is generally the others who have the necessary leisure and money—who desire to lessen the strain of professional life by a week-end resort of their own not too far from their place of occupation. For houses in foreign parts suggestions are made for the adoption of local ways and materials, modifying them so as to engraft the essentials of British or American ideas on the general local style, which is usually an evolution due to local circumstances, though apt to persist after the disappearance of the conditions that originally gave rise to it.

The Views of "Vanoe": An Englishman's Outlook. By ARNOLD WHITE. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1910. Pp. 419. Price 5*s.* net.—These views are expressed in a felicitous way that makes them pleasant reading. They cover a wide range of subjects—occultism, politics, social economics, moral characteristics of races and individuals, &c. One section is devoted to eugenics. Much sound personal hygiene is inculcated. There is not a little criticism of the medical profession, some of it doubtless more or less deserved, but it is tempered with a generous recognition of the disinterestedness of the profession as a whole. The section concerning health contains many sensible observations on socio-economics, among which we are glad to see the contention that national health demands that a free hand under proper conditions shall be given to scientific research as it is to explorers of the Poles. The

author is at his best in the discussion of social problems, wherein he expresses straight thoughts in clear phraseology. We could easily find points to take exception to, as could everyone interested in any of the matters discussed; but that is merely because in all such problems no view-point can proportionately encompass the whole of truth, so that each observer naturally gives prominence to, and even possibly somewhat distorts, the side most immediately in view. But we do not wish to cavil, preferring to read and enjoy these reflections of a careful observer, an acute reasoner, and a broad-minded thinker.

A BATCH OF ANNUALS.

1. *The Official Year Book of the Scientific and Learned Societies of Great Britain and Ireland.* Twenty-seventh annual edition. London: Charles Griffin. 1910. Pp. viii.-370. Price 7*s.* 6*d.*

2. *The Englishwoman's Year Book and Directory.* 1911. Edited by G. E. MITTON. London: Adam and Charles Black. Pp. xxiv.-386. Price 2*s.* 6*d.*

3. *The Writers' and Artists' Year Book.* 1911. London: Adam and Charles Black. Pp. viii.-130. Price 1*s.*

4. *Whitaker's Almanack.* 1911. By JOSEPH WHITAKER, F.S.A. London: 12, Warwick-lane, E.C. Pp. 971. Price, cloth, 2*s.* 6*d.*

5. *Whitaker's Peerage, Baronetage, Knightage, and Companionage for 1911.* London: 12, Warwick-lane, E.C. Pp. cii.-812. Price 5*s.* net.

6. *Who's Who.* 1911. London: Adam and Charles Black. Pp. xxvi.-2246. Price 10*s.*

7. *Pears' Shilling Cyclopædia.* London: A. and F. Pears. Pp. ii.-1022. Price 1*s.*

1. This year book will prove of value to science students. It gives a classified list of the various scientific societies, with the names of their officers, the addresses of the secretaries, their objects, occasions of meeting, membership requirements, and the periodical and other publications of the society. These are followed by a list of the papers read during the session of 1909–10, arranged alphabetically under authors' names. Section XIV. is devoted to medicine and covers 60 pages. It gives the foregoing details in reference to the Local Government Board, the Royal Society of Medicine, the Royal Medical Society of Edinburgh, and the Royal Academy of Medicine in Ireland, the Medical Society of London, the British Medical Association, the Harveian Society, the Lister Institute, and of the most important medical societies in London, the provinces, Scotland, and Ireland. There is also a list of other medical societies, which occupies two pages of small print. Besides the section on medicine, there are other sections dealing respectively with physics, chemistry, biology, economics, psychology, and science generally, as well as with law, mechanics, literature, &c. A cross reference in Section VIII., Naval and Military Science, to the United Services Medical Society, which appears under Section XIV., may be suggested as an improvement in the future.

2. The thirteenth issue of the *Englishwoman's Year Book* shows a new departure in arrangement which should greatly enhance its usefulness. The work is divided into two parts, the first of which deals with education, professions and occupations, and social life; the second with philanthropic and social work. In the first part, the second and third sections, which deal respectively with Universities and Research work and with Medicine, Pharmacy, and Dentistry, are of direct interest to medicine, and especially to medical women; while under Employments and Professions, in Section IV., information of particular interest to the medical profession is found under the headings of Factory Inspectors, Hospital Almoners, Hygiene, Nurses for Children and Sick Nursing, Physical Training, Research Work, Sanitary Inspectors, &c. The subject of sick nursing is satisfactorily dealt with. Part II. contains sections on Charitable Organisations, Homes, and Societies for Children, Girls, and Young Women, Industrial Matters (factory and workshop labour, &c.), and Hospitals and Convalescent Homes. The book contains a table of university scholarships for women and a good index. It deserves hearty commendation.

3. *The Writers' and Artists' Year Book* is a useful work of reference for writers generally, a large and increasing number of whom are now to be found in the medical profession. It contains lists of journals and magazines, both British and American, with details as to their character, scope, requirements, the remuneration given, and so forth; also lists of syndicates that buy manuscripts, of literary agents, publishers, music publishers, and information on special subjects, such as Christmas card making and other similar work, and press-cutting agencies.

4. *Whitaker's Almanack* has long since established itself as a public necessity, and the present (forty-third) issue, being that of an epochal year, contains more than the ordinary amount of alterations, &c., necessitated by the death of King Edward VII., the accession of His Majesty King George V., and the General Election of January last. It was impossible to await the results of the recent General Election and at the same time to ensure early and simultaneous publication in all European cities, and for Christmas and New Year in distant parts of the world, so a coupon is issued in the preface, which, when duly filled in and forwarded prepaid to the office of the Almanack, will entitle the sender to receive post free a supplement containing the latest Parliamentary information. The usual retrospects are present, to which may be added articles on the military and educational systems of the world, on naval progress among the maritime powers, the administration of the British army, extended and cheaper imperial telegraphy, and so on. The scientific summary is this year omitted.

5. *Whitaker's Peerage* describes itself in its title. It has successfully met the various tests to which we have submitted it with a view to demonstrate its completeness and accuracy.

6. The popular and useful reference book, *Who's Who*, is a biographical dictionary of living people who have been born distinguished, have achieved distinction, are grappling for distinction, or have had distinction thrust upon them. The work is again increased in size, and contains notes of a fair proportion of names of those notable in medicine and the allied sciences. For the man of affairs it provides a good *résumé* concerning persons in, or near, the public eye, of the estimation in which the public holds them, or in which they hold themselves. To journalists in these days the book is simply indispsenable.

7. *Pears' Cyclopædia* includes 18 distinct works of reference under the editorship of James Burnley, with eight assistants. It contains dictionaries of the English language, of general information, prominent people, classical information, everyday information, a world gazetteer, an atlas, dictionaries of events, gardening, poultry and birds, cookery, health, sports and pastimes, the toilet, business, photography, the nursery, and a ready reckoner from 1-16*d.* to 21*s.* It is a small reference library of itself, at a price within everyone's reach.

DONATIONS AND BEQUESTS.—Among other bequests the late Mr. John Bradshaw, of Cheltenham, left £1000 to the Lancaster Royal Infirmary for the purpose of endowing a "John Bradshaw" bed; £500 to the Royal Infirmary, Manchester; £300 to the Home for Incurables, Harrogate; £200 to the Cheltenham General Hospital, and £100 to the Harrogate Infirmary.

THE LANCET.

LONDON: SATURDAY, DECEMBER 31, 1910.

THE ANNUS MEDICUS 1910.

NOT only custom leads us year by year to carry out a medical stock-taking at Christmas-time; we know that our annual summary is of service to many of our readers, and especially is it useful for future reference. That Medicine has advanced during the last 12 months we have no doubt, though the time is too early to pick upon any given piece of recorded work and point to it as the beginning of a new principle or the embryo of a method of treatment with which great things will be wrought. Our present stock-taking possibly leaves out of notice some innovation destined in the near future to have great significance; and possibly again it may attribute undue mportance to something which is on the edge of being superseded. A *résumé* of this nature, whatever pains be spent upon it, must necessarily fall short of completeness, but we are encouraged to continue the custom of our predecessors and to add another chapter to the history of modern medicine that has been compiled in these pages, and in its present form, for over 40 years, nearly half the lifetime of THE LANCET. Year by year the chapters have grown longer, and space forbids us to make each of them more than an expanded index, but it is, we trust, a discriminating index. Each year, too, the record of medical events, not strictly scientific, becomes longer, as medicine and hygiene enter more prominently into the counsels of the nation and into the daily consideration of our countrymen; this is abundantly evident in this story of the Annus Medicus for 1910.

MEDICINE.

Vaccine Therapy.

THE subject of vaccine therapy has commanded a large amount of attention during the year, and numerous contributions have been made to the literature concerning it. An important discussion on Vaccine Therapy, its Administration, Value, and Limitations was held at the Royal Society of Medicine and occupied six sittings. The discussion was opened by Sir ALMROTH WRIGHT, and numerous speakers related their experiences and the conclusions at which they had arrived. The new features in regard to vaccine therapy are its widespread applications, its development in regard to mixed infections, and the claim that it should be controlled by the opsonic index. Sir ALMROTH WRIGHT in his opening address referred to the relations of the bacteriologist and the practising physician to one another and to the patient. There will probably not be a general agreement with his contention that there is a desire on the part of clinicians to oppose the application of bacteriological methods, to belittle the achievements of the bacteriologists, or to prevent them from receiving their due professional recognition and emoluments. General support, however, will be given to the statement that an acquaintance with bacteriological methods sufficient to enable them to be utilised practically should be part of the curriculum of every medical student. Every patient must be studied at the bedside, and purely laboratory investigations can never with safety replace the careful observation of the patient and his symptoms which forms the basis of clinical medicine. But there can be little doubt that methods of diagnosis and means of treatment will be evolved in laboratories to an increasing extent, in the application of which clinical knowledge and experience must continue to be of importance. One of the striking features of the discussion was the fact that the speakers almost without exception testified to the value of the method of treatment by vaccines. The actual points which came in for criticism and discussion were the limitations of the method and the various modes of administration. The postulates laid down by Sir ALMROTH WRIGHT were in brief the necessity for an exact and complete bacteriological diagnosis, kept up to date during the treatment; the necessity for bacteriological knowledge on the part of the person employing the method; and the facts that there are definite limits to the responsive power of the patient, that successful results can only be obtained where an efficient lymph-stream can be conducted through the foci of infection, and that in long-standing infections a long series of inoculations may be necessary. He also mentioned that in a not inconsiderable percentage of cases it is essential to success that the dose of vaccine shall be controlled by measurements of the opsonic index. Those who took part in the discussion were members of different branches of the medical profession, and the net result of the discussion was to indicate a widespread belief in the usefulness of vaccine therapy and to prove an expectation of great results from it in the future, when the questions of the proper control of dosage have been more definitely worked out. The methods of administration were carefully discussed, but much investigation is still required before the limitations of this therapeutic measure can be in any way defined. The nature and treatment of mixed infections require close study, and the results of those who are now investigating the matter will be awaited with interest.

Tuberculosis.

The aspects of tuberculosis which have mainly attracted attention during the past year have been its bacteriology, its occurrence in children, and its prophylaxis. In delivering the Milroy lectures Mr. A. G. R. FOULERTON chose as his subject the Streptotrichoses and Tuberculosis. He dealt fully with the evidence which he found available in support of the following propositions: (1) That under the name of "tuberculosis" there are commonly included infections caused by more than one species of parasite; and (2) that the parasites, generally reputed to be bacilli, which are the cause of tuberculosis belong in reality to a higher group of organisms, and, as streptotricheæ, must be included with the hyphomycetes, or mould fungi. He also discussed the unity of tuberculous infections. He mentioned five distinct types: (1) Tuberculosis occurring in fishes and other cold-blooded species; (2) avian tuberculosis; (3) tuberculosis of the rat; (4) bovine tuberculosis; and (5) human tuberculosis. In referring to avian tuberculosis, Mr. FOULERTON said that when the pathogenic activity of the parasites of human and avian tuberculosis is compared, strongly marked differences suggest the separate identity of the two species, and he quoted experiments which showed the difficulty that was experienced in infecting poultry, pheasants, and pigeons by the human parasite. He also considered that the parasite of rat tuberculosis was specifically different from either the human or avian parasite. With regard to intercommunicability of human and bovine tuberculosis, he believed that, whilst the human adult was susceptible only, or only in any important degree,

to infection by parasites from a human source, the child was equally susceptible to infection by either species, "human" or "bovine."

The occurrance of tuberculosis in children has been considered by various observers. At the annual meeting of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis, Dr. FRANZ HAMBURGHER (Vienna) read a paper on the Frequency of Tuberculosis in Childhood, in which he maintained—(1) that the majority of persons become infected by tuberculosis in childhood; (2) that the frequency of tuberculous infection increases from year to year, while tuberculous morbidity—that is, the frequency of manifest tuberculous disease—decreases from year to year; and (3) the prognosis of tuberculosis in childhood becomes more favourable the older the individual is at the time of the first infection. A debate followed on this paper, the discussion revealing the comparative frequency of abdominal tuberculosis among children. It appeared that this frequency was very marked in Edinburgh and Glasgow, but was probably dependent upon bad milk-supply and not bad air, as cases were cited where town-bred children had derived tuberculosis while in the country from drinking tainted milk warm from the cow.

Dr. CLIVE RIVIERE published a paper in our columns entitled "Phthisis in Children,"[1] in which he contended that the term "phthisis" should be reserved, when speaking of children, for a disease identical with phthisis in the adult, and should not be used to cover all forms of pulmonary tuberculosis. He considered that, using the term in its proper meaning, phthisis is not a common form of tuberculous disease in childhood. He also stated that fatal tuberculosis is (comparatively) uncommon at school ages, the bulk of tuberculous infection during this period being localised and recoverable. Finally, he was of opinion that when the disease occurs in children it is eminently curable in the early stages, but that when fatal it generally runs a shorter course than in the adult.

In regard to measures to be taken to prevent the spread of pulmonary tuberculosis, the establishment of dispensaries for tuberculosis has been much discussed. As early as 1887, Dr. R. W. PHILIP founded the Royal Dispensary for Consumption in Edinburgh. The movement now shows signs of being more widely adopted. A dispensary has been in operation for over a year in Paddington, and similar institutions are being established elsewhere. In Marylebone, for instance, one will probably be in active work by the end of the year. When a patient has been seen at the dispensary and pronounced tuberculous, his home is visited by the nurse, who fills up a careful register of its hygienic and economic conditions, which is countersigned by the medical officer after he has paid a visit for himself. His treatment of each case is thereafter conditioned entirely by the environment of the patient. He gives personal advice upon the best methods of obtaining open-air treatment in a small tenement, to certain cases he lends open-air shelters, and he always refrains from ordering expensive nourishment for a person who is obviously unable to obtain it. It is a sound feature of the system that the treatment of no case which is already in medical hands is undertaken without the written consent to such a transference of responsibility being first obtained from the medical man in attendance. The experience both at Edinburgh and at Paddington is that private practitioners frequently send their poor cases to the dispensary either for consultation or for treatment, whilst the out-patient departments of general hospitals are not less quick to free themselves of the responsibility of cases for which their system of treatment, allowing of no home supervision, is confessedly inadequate.

[1] THE LANCET, Jan. 15th, 1910, p. 156.

At the meeting of the National Association to which we have referred many subjects were discussed, and in particular the measures which should be taken to prevent tuberculosis. The publicity which is at present being given to the subject of tuberculosis in the lay press renders it a matter of great importance that the funds subscribed and the enthusiasm awakened shall be directed into the most profitable channels, and that not all of it shall be expended in a somewhat one-sided campaign against the bacillus. All authorities on the subject are agreed that tuberculosis is very largely a social disease, intimately bound up in one way or another with the problems of poverty, and notably with the housing and feeding of the poorer classes. It is known that the disease is found in intimate association with back-to-back houses, overcrowding, and under-feeding, and that the removal of these states and conditions is followed by a diminished death-rate from pulmonary tuberculosis. So much is this the case, that could there be a general crusade both in urban and rural districts against bad housing a greater effect would probably be produced upon the rapidly declining tuberculous death-rates than would be likely to ensue from any other single event—greater, perhaps, than might be expected from all the other agents of prevention combined.

The question of the notification of pulmonary tuberculosis has again attracted attention, and voluntary notification has been adopted in many of the London boroughs and elsewhere; but the procedure has not yet been long enough in force for any definite judgment to be formed as to the influence it has on the incidence of the disease.

Typhoid Fever.

Lieutenant-Colonel D. SEMPLE, R.A.M.C. (retired), made some investigations in order to ascertain whether there was any advantage to be gained by substituting intramuscular inoculation of bacterial vaccines for the usual practice of subcutaneous inoculation. In regard to typhoid fever, he found that the immunising response following the inoculation of typhoid vaccine in rabbits, as measured by the presence of agglutinins and opsonins in the blood, is the same whether the vaccine is given subcutaneously or intramuscularly. In both methods of inoculation the agglutination and opsonic changes, when plotted on a chart, were found to take somewhat similar courses, and in both an increase of agglutinins practically means an increase of opsonins. The conclusion was therefore arrived at that the intramuscular method of inoculating bacterial vaccines possesses no advantages whatever over the subcutaneous method, and as the latter gives rise to less pain and inconvenience it is to be preferred.

Scarlet Fever.

An epidemic which presented interesting characteristics occurred at Ingatestone, in Essex. This village, which has a population of about 1000, after being practically free from the disease for many years, had the infection introduced, and all the early cases were of so mild a character that they only became recognised when desquamation occurred. A very careful search for missed cases and strict attention to the children attending the public elementary schools appeared to have arrested the spread, when suddenly a series of nine cases occurred. During the next five weeks two or three cases occurred weekly, then suddenly 20 cases occurred in one week, after which the infection rapidly subsided. Milk came under suspicion at the earlier outbreak, and throughout the whole period over 80 per cent. of the houses invaded obtained milk from the same source. This in itself was almost sufficient to implicate the milk, but other facts, which the milk theory seemed incapable of explaining, had to be taken into consideration. Practically all the cases occurred in a limited area, whereas the milk-supply extended over a much larger area. The largest consumers of milk

within the infected area were but little affected, and beyond this area they were not affected at all. Every attempt to account for this circumscribed diffusion failed, and the source of origin remained obscure. Dr. J. C. THRESH, the medical officer to the Essex county council, in his special report pointed out many other peculiarities of the outbreak, such as the age and sex incidence, and notably the escape of those who drank raw milk, whilst those who only used milk in tea were attacked.

Acute Anterior Poliomyelitis.

At intervals during the last five years epidemics of acute anterior poliomyelitis have appeared in different parts of the globe, some of them of peculiar severity and extent. Norway, Sweden, New York and the New England States, Australia, various parts of Germany and Austria, France, Holland, and England have all been visited. As a natural consequence of these somewhat alarming occurrences—for the mortality throughout has been considerable—attention has been concentrated on the disease, and the problem of its nature and etiology has been attacked with vigour. Contributions on the subject have appeared in medical journals, and an immense advance has been made in the knowledge of this malady. One result is that it is evident that the conceptions of the disease must be widened as far as its seat in the spinal cord is concerned. Hitherto too much reliance has been placed on the study of chronic instances of the complaint, whereas in all the epidemics innumerable opportunities have presented themselves of observing it in the earlier stages. Thus it has become certain that meningeal symptoms are far from uncommon, as exemplified by pain and stiffness of the neck, pain on any movement of the head, sometimes a degree of opisthotonos, pain and stiffness along the spine, and sometimes on pressing the vertebræ. Kernig's sign has not been wanting in numbers of cases. Almost invariably, however, these meningeal symptoms are confined to the spinal cord. The meningitis, moreover, has been easily recognisable post mortem in many cases, consisting in infiltration of the meninges, some thickening of them, and engorgement of the blood-vessels. In a small number of cases, relatively, the posterior horns and posterior root ganglia have been invaded, although the main seat of the disease remains in the cornua. For this reason, amongst others, it would seem desirable to describe the disease as acute or epidemic poliomyelitis; the designation "infantile" should be abandoned, and perhaps also the word "anterior."

In 1909 there was an epidemic of poliomyelitis along the seaboard of New England, and Dr. FLEXNER and his associates at the Rockefeller Institute succeeded in obtaining material from the central nervous system from two patients who died. They found that the toxin or toxic agent can be transmitted to apes, producing the characteristic symptoms of the disease, but the potency of the virus is not thereby lessened; after a slight attack reinoculation is almost impossible. As regards the nature of the virus, it is very active, but invisible even by special illumination. It is not arrested by the finest filter. So far, the investigators have not succeeded in staining it nor in cultivating it, unless a cloudiness in certain media may be regarded as a culture. These cultures do not transmit the disease, thus differing from the invisible organism of pleuro-pneumonia. The virus resists a temperature of −2° C. for 30 days. Drying for seven days over caustic potash does not diminish its virulence, nor does admixture with glycerine. It even resists 5 per cent. phenol. Numerous suspensions in water and long keeping do not render it inactive; but it is sensitive to heat, becoming inert at 45° C. In its transmissibility it shows many analogies with the diplococcus intracellularis; and Dr. FLEXNER believes that both organisms enter and leave the body *viâ* the nares, the cribriform plate, and the cerebro-spinal fluid. It is interesting to note that in Professor WEICHSELBAUM'S laboratory operators have also succeeded in inoculating the monkey with the virus of poliomyelitis.

Plague in England.

In the month of September four patients died at Freston in Suffolk from a disease the nature of which was uncertain. Suspicion arose that the deaths might have been due to plague, the pneumonic symptoms being capable of explanation in that way. A bacteriological examination was made in regard to material taken from two of the patients, and although opinions were not unanimous, it certainly seemed possible that the pneumonia had been due to plague. Subsequently rats and hares, found dead or dying in the same locality, have been examined, and some were found to be infected with plague. An active crusade against rats was then put into operation, which has resulted in the weekly destruction of thousands of these vermin and their attendant fleas, any of which may have been carriers of plague bacilli. Considerable speculation has arisen as to the length of time during which this rat plague had been in existence in East Suffolk, and as to whether anything approaching a similar state of affairs exists elsewhere unrecognised; no definite decision has yet been given.

Sleeping Sickness.

Sir HENRY HESKETH BELL, K.C.M.G., late Governor of the Uganda Protectorate, and now High Commissioner of Northern Nigeria, has provided an extensive report on the measures adopted for the suppression of sleeping sickness in Uganda. After dealing with the prophylactic measures which had been taken he proceeded to consider the results of treatment. In spite of the continuous efforts that have been made to discover a cure, Sir HESKETH BELL considers that not much progress has been made. Treatment by injections of atoxyl and of allied drugs, in which great hopes were at first placed, has not given the results expected. In some instances, indeed, atoxyl caused blindness to such an alarming extent that its use had to be greatly restricted. Mercury in conjunction with atoxyl seems to have given more satisfactory results, but, adds Sir HESKETH BELL, "I think I am correct in saying that we are still unable to produce a single undoubted cure among all the thousands of cases which have passed through our segregation camps or elsewhere. All that can be claimed for some of the drugs used is that in a great number of cases they seem to have prolonged the lives of the patients and to have somewhat reduced the acuteness of their sufferings. Sooner or later, however, the unfortunates all seem to die, and unless a therapeutic cure can soon be discovered every soul affected will succumb to the disease." This, however, is rather a sweeping statement; certainly several observers hold the opinion that atoxyl can cure a number of cases if the treatment be begun early enough.

Diseases of the Heart.

In delivering the Bolingbroke Lecture before the South-West London Medical Society Dr. NORMAN MOORE referred to certain points in connexion with diseases of the heart which are of considerable significance in diagnosis and prognosis. He again expressed his opinion that in every case of rheumatic pericarditis an endocardial murmur will sooner or later be heard. If, therefore, pericarditis long persists without any murmur being heard, some other cause than rheumatic fever must be looked for. Conversely, the presence of a murmur in a patient known to have previously had normal heart sounds will sometimes make it clear that a supposed injury is not the cause of a pain in the knee or ankle, but that the patient has rheumatic fever. He also referred to the bacteriology of endocarditis. He remarked

that in the present state of bacteriological knowledge it is often difficult to determine whether the endocarditis progressing in a patient is of the kind belonging to rheumatic fever or is a true ulcerative or malignant endocarditis. The presence of streptococci in the blood will sometimes indicate a malignant form of endocarditis, but often the blood culture yields an inconclusive result. Time seems at present a necessary aid to solving the problem of the presence or absence of malignant endocarditis; but it may be expected that bacteriology will soon supply an earlier determination of the nature of such cases. In discussing the prognosis of mitral regurgitation Dr. MOORE expressed the opinion that such complete compensation may take place that the condition need not interrupt even an active career in life. He thought that the most important point in treatment is to avoid further endocarditis and consequent further valvular injury. He believed that the cause of death in the majority of patients is not merely the condition of the valves and the endocardium, or of the myocardium, but of the whole heart and the whole circulation.

As Lumleian Lecturer at the Royal College of Physicians of London Professor WILLIAM OSLER chose for his subject Angina Pectoris, and gave a learned disquisition on several aspects of the disease. In regard to the cause of the pain in this condition, he said that angina results from an alteration in the working of the muscle fibres in any part of the cardiovascular system, whereby painful afferent stimuli are excited. Cold, emotion, and toxic agents interfering with the orderly action of the peripheral mechanism increase the tension in the pump walls or in the larger central mains, causing strain, and a type of abnormal contraction enough to excite in the involuntary muscles painful afferent stimuli. He was further of the opinion that in disturbance of the Gaskellian function is to be sought the origin of the pain, whether in heart or arteries. The lecturer continued that spasm or narrowing of a coronary artery, or even of one branch, may so modify the action of a section of the heart that it works with disturbed tension, and there are stretching and strain sufficient to arouse painful sensations. Or, he said, the heart may be in the same state as the leg muscles of a man with intermittent claudication, working smoothly when quiet, but instantly an effort is made, or a wave of emotion touches the peripheral vessels, anything which heightens the pressure and disturbs the normal contraction, brings on a crisis of pain.

Diseases of the Nervous System.

The localisation of cerebral function was considered by Dr. J. SHAW BOLTON in the Goulstonian Lectures delivered before the Royal College of Physicians of London. Dr. BOLTON had conducted a new and important anatomical and embryological investigation in regard to the cerebral cortex, and had obtained some interesting results, though this was but a preliminary to the development to his main thesis. This thesis is that the essential physical basis of mental disease consists, on the one hand, in a true sub-evolution, or defect of development, of the cell laminæ of the cortex; and, on the other, in degrees of decrease of the cell laminæ, which is of the nature of a true involution or dissolution. His conclusions were based on the average measurements of 30 cases of mental disease, grouped under visuo-sensory, visuo-psychic, and prefrontal regions. Dr. BOLTON finds that a definite relationship exists between the depth of the prefrontal cortex of the respective cases and the degree of amentia or dementia which existed. No such relationship obtains in the case of the other two regions measured. Further, in considering the individual cell laminæ he concludes that the inner cell lamina is the fundamental cell layer of the cortex, and is concerned with the performance of the instinctive activities. It is below the normal depth in the prefrontal cortex of imbeciles and dements unable to attend to the calls of nature or to feed themselves; while the second or pyramidal layer is concerned with the psychic or associational, in contra-distinction to the instinctive, activities of the cortex.

In the Morison lectures delivered before the Royal College of Physicians of Edinburgh Dr. W. ALDREN TURNER discussed the Nature and Treatment of Epilepsy. In regard to therapeutics, he made some interesting remarks on the dietetic treatment of the disease. He had adopted a purin-free diet, or a modification of it, containing, according to the needs of individual cases, a small portion of fish either once daily or three times a week for several years in conjunction with the bromides or Gelineau's dragées. The results were such that he had been led to advise it in all cases of recent epilepsy. In cases in which the bromides alone had been of little or no use the adoption of the purin-free saltless diet at once led to material improvement. By its aid the dose of the bromides could be largely reduced, and if properly supervised symptoms under such conditions never appear. If the patient showed any signs of loss of weight the addition of cream or cod-liver oil was usually sufficient. If not sufficient, fish, or even a little lamb or mutton, could be added to the diet.

The Actions of Pituitary Extracts.

Dr. ARTHUR DELILLE, who has devoted considerable attention to some of the effects of opotherapy, has published an important monograph on the subject of the pituitary body. An interesting account of the structure and functions of this organ is given, as well as a critical review of the work of previous investigators, and an ample bibliography. He records the results of his own studies, which comprise both experimental and clinical observations carried out in collaboration with Professor L. RENON. After a review of the symptoms produced by a deficient and excessive action of the pituitary respectively, he reviews its employment for clinical purposes. He recommends it in cases where it is desired to raise the blood pressure, lessen the rate of the pulse, produce diuresis, suppress painful sensations of heat and produce perspirations, improve the appetite and capacity for sleep, combat asthenia, and exert a stimulating effect upon nutrition. He advises that it should not be given when the blood pressure is high, and that it should not be combined with suprarenal extract. He recommends the use of an extract of the whole gland, since it is nearly as active as that of the posterior lobe only, and being more easy to prepare is less costly. He states that the daily dose administered for therapeutic purposes should not exceed a quantity corresponding to half a fresh gland of the ox, that the patient should be carefully observed, and that the arterial pressure should be taken as a guide to the necessity of modifying the dose given. Dr. DELILLE gives details of its use in a considerable number of different conditions, including typhoid fever, tuberculosis, certain cardiopathies, Graves's disease, paralysis agitans, and some defects of growth. Dr. S. JERVOIS AARONS in a recent paper in our columns described the use of pituitary extract in obstetrics and gynæcology, and came to the conclusion that low blood pressure and a generally flabby condition warranted a trial of the treatment.

Ringworm.

Recognising the grave prevalence of ringworm and the disastrous influence which this prevalence has upon the education of children, we invited two thoroughly competent dermatologists to make an inquiry for us into the whole question as it at present affects the school children of the metropolis. Their report was published in THE LANCET of Jan. 1st of this year (p. 51). One of the most suggestive parts of that report was the opinion on the results of the X ray treatment. There is a great unanimity amongst those

who have had much experience with this form of treatment of ringworm that it is rapid and certain and free from risks in the hands of those who thoroughly understand it, but there is still a great deal of diversity of opinion as to many of the details. The points which seem of importance are the following. The scalp should be deprived of its hair in as few applications as possible. If any circular shield or stops be employed it must necessarily follow that either there must be areas of overlapping or areas untreated by the rays. When only small areas are to be treated the hexagonal lead-glass stops are preferable to the circular, because hexagons can be fitted into one another. More simple still is the method of using no shields, employed at the Ringworm Hospital of the Metropolitan Asylums Board. The strength of the secondary current from the coil should be controlled by observations of a milliampère-meter and of a spinter-meter, but, above all, Sabouraud's pastilles, prepared from trustworthy material, should be employed. In nearly all cases the whole head can be epilated in five, or at the most six, exposures. The nape of the neck seldom needs treatment and may usually be neglected. The ears, the nose, and the neck generally require to be shielded.

Lectures of the Year.

The Lumleian lectures were delivered by Professor WILLIAM OSLER on Angina Pectoris. We have already referred to some of his remarks under the heading of Diseases of the Heart. Dr. JOSEPH SHAW BOLTON was the Goulstonian lecturer, selecting as his subject, A Contribution to the Localisation of Cerebral Function, based on the Clinico-pathological Study of Mental Disease. Recent years have seen considerable advances in the knowledge of cerebral function and its exact localisation. Yet the impression left by a perusal of the elaborate and painstaking researches of Dr. BOLTON is not so much one of wonder at what has been accomplished as almost of dismay at what remains to be performed. We have referred to these lectures under the paragraph dealing with diseases of the nervous system. The Bradshaw lecture was delivered by Dr. G. NEWTON PITT, who chose as his subject, The Results of Bronchial Obstruction. He first drew attention to the numerous results which may follow the compression of a bronchus. He described the factors which lead to dilatation of the bronchial tubes, which he believed to consist in local changes in the walls, the accumulation of secretion under tension, and the effects of inspiration of a lung which is not capable of expanding satisfactorily. He then considered in detail the causes of bronchial obstruction. These may be either external or internal, the external being aneurysm of the aorta, malignant disease (either of the bronchial glands or of the œsophagus), enlarged caseous or suppurating glands, gummata, abscess, and dilated left auricle; the internal causes being bronchiolitis, syphilitic ulceration with scarring, primary malignant disease of a bronchus, and foreign bodies in the bronchus. Dr. F. W. ANDREWES gave the Croonian lectures on the Behaviour of the Leucocytes in Infection and Immunity. He drew attention to the important rôle played by the bone marrow in immunity. He reminded his hearers that the marrow is the mother tissue of the white cells. If there is an urgent call for more leucocytes there is a "leucoblastic" reaction, which is commonly a neutrophil leucoblastic reaction, because the need for an increase in the polynuclear leucocytes is a much more common thing than the need for eosinophils, basophils, or lymphocytes. Dr. ANDREWES said that it would seem that the "plant" for the production of polynuclear leucocytes present in normal marrow, though it may suffice for a high transitory leucocytosis, is quite inadequate for the *maintenance* of a high leucocytosis. In presence of a grave pyogenic infection steps are at once taken to increase the plant necessary to keep up a due supply. In spite of this the patient or the animal may die, but he thought it is permissible to assume that in every case showing a sustained circulatory leucocytosis this marrow reaction is present. We have referred to the Milroy lectures delivered by Mr. FOULERTON on the Streptotrichoses and Tuberculosis. The Oliver-Sharpey lectures were given by Dr. F. W. MOTT, who selected as his subject the Cerebro-spinal Fluid. He first discussed its physiology, pointing out its physical and chemical properties, its source, its destination, and its functions. He then considered its pathology, laying stress on the changes which are found in sleeping sickness, syphilis, and parasyphilis. Dr. H. B. DONKIN was the Harveian orator, his subject being Some Aspects of Heredity in Relation to Mind.

SURGERY.

The Preparation of the Skin for Operation.

The preparation of the skin for operation has ever since the introduction of antiseptic surgery been looked upon as of vital importance, and inasmuch as sterilisation by heat is here impossible we have to trust to mechanical cleansing and to the use of antiseptics. The practice has certainly varied greatly in different parts of the world, and even in the hospitals of the same city, but it has for the most part consisted in the application for 12 hours or more of a compress moistened with some antiseptic after thorough washing of the operation area. This method, though of very definite value, is not free from objections; in the first place, it is not at all rare to find the skin inflamed by the compress, and in some cases the irritation may be great; a further objection is that the method is inapplicable to emergency operations, for sufficient time is not available. Nearly 50 years ago BOINET wrote in favour of iodine as a local application in surgery. In 1906 CHASSEVANT recommended the use of a solution of iodine in chloroform of the strength of 1 part in 15 for the disinfection of the skin. GRÖSSICH has also employed the tincture of iodine for the same purpose. In THE LANCET Mr. H. F. WATERHOUSE and Mr. W. STEPHEN FENWICK described the method employed at Charing Cross Hospital. At first the iodine was applied only after thoroughly washing with soap and water and the employment of an antiseptic solution, but the results were unsatisfactory, till it was found that the preliminary washing was not only unnecessary but a positive hindrance to the penetration of the iodine. When the washing of the part was omitted the action of the iodine was very satisfactory, and most of the incisions healed by first intention. The best strength of the iodine solution had then to be determined; an 8 per cent. solution was at first employed, but it was found to cause much irritation, and later a 2 per cent. solution was used, and with the results of this strength they were quite satisfied. They lay stress on the importance of using rectified spirit as the solvent, for if the iodine is dissolved in methylated spirit the eyes of the surgeon and his assistants are liable to suffer. WATERHOUSE paints the operation surface first two hours before the operation and again on the operating-table. Many surgeons are now employing iodine in much the same way, but various modifications are used. A slightly weaker solution is equally efficacious, and one painting immediately before the operation appears to be successful. The value of iodine as a disinfectant has long been recognised, and PAUL RECLUS has called attention to the great value of iodine in the treatment of wounds of the hand. In the hands of workmen the skin is often thick and covered with a crust of grease and dust, and it is very difficult to sterilise the skin, but if tincture of iodine is applied direct to the wound and its margins rapid healing is the rule. It is worthy of note that in the Russo-

Japanese war tincture of iodine was largely used, and this was one of the causes of the success of the treatment of wounds in that war.

Antiseptic and Aseptic Methods of Operation.

The relative value of the "antiseptic" method as taught by LISTER and the modern "aseptic" method has been the subject of a discussion in the columns of THE LANCET. There appear to be misconceptions among some surgeons as to the exact procedure in an "antiseptic operation," but, as Sir WATSON CHEYNE has said, it is not a question of the materials employed or whether rubber gloves are used or not, it is in the manipulations carried out by the surgeon that the essence of the matter lies, and the personal equation of the operator has more to do with the result than anything else. With either "antisepsis" or "asepsis" it is possible to obtain perfect results, but either method can easily be practised so as to lead to failure, more or less complete.

Momberg's Method of Hæmostasis.

The arrest or prevention of hæmorrhage in operations is often of the greatest moment, and one of the more powerful methods of controlling hæmorrhage in operations on the lower half of the body and on the lower limbs is that introduced by MOMBERG. It was first described in 1908 and consists in applying a thick rubber tube tightly round the waist. It is certainly very effective, and it has been widely employed on the continent, though but little in this country. Although in several cases some troublesome symptoms have appeared, only one fatal result had been recorded until recently, but a second fatal case has been observed by Professor GROSS and Dr. ANDRÉ BINET of Nancy. The patient had a knee completely disorganised by tuberculosis, and it was decided that amputation of the hip-joint was the best treatment. As she was much wasted and in a very bad general condition it was resolved to employ MOMBERG'S method, so that she might lose as little blood as possible. The operation went off well until at the very moment when the rubber tube was completely relaxed the pulse suddenly stopped and the patient became pale. At the necropsy, on the left side of the heart there were vegetations on the mitral and aortic valve with some fatty degeneration of the heart muscle. It would be a misfortune if these two fatal cases should lead to the abandonment of MOMBERG'S method of hæmostasis; the chief measure of precaution would appear to be a very slow application of the tube and an equally slow removal.

Microscopic Examination of Tumours at Operation.

The importance of the surgeon knowing at the time of operation the exact nature of a tumour can hardly be overestimated, and many attempts have been made from time to time to examine microscopically tumours and other diseased tissues during the operation, and various degrees of success have followed these attempts. Mr. ERNEST H. SHAW contributed to our columns a useful paper on the methods he employed for the examination of the tumour during the course of the operation. Mr. SHAW has found that he is able within five minutes, or even less, to give a report which shall be of use to the surgeon. To prolong an operation to the extent of five minutes so as to perfect a diagnosis is perfectly justifiable, and the methods he employs would certainly often prove useful, though it must surely happen that in no small proportion of the cases an exact diagnosis by microscopy is not possible.

Surgery of the Heart.

From time to time fresh cases of the suture of heart wounds are recorded, and a very striking instance was reported by Dr. C. H. PECK of New York City. The patient was a coloured girl, 24 years old, and was stabbed in the chest with a pocket-knife about half an hour before admission to the hospital. The pericardium was filled with blood and the intra-pericardial tension was so great that no heart beat could be felt even by the finger on the sac. The right auricle had been wounded and the incision was nearly half an inch long. Four sutures were inserted and the patient completely recovered. The heart is much more tolerant of surgical interference than surgeons thought a few years ago. The cases in which an unwounded heart is operated on are necessarily much rarer, and therefore it is of interest to read of a case of heart puncture recorded in THE LANCET by Mr. GAY WALLACE MILNE of Aberdeen. The patient was a girl, aged 20 years, and her heart had been damaged by an attack of rheumatic fever. She suffered from great dyspnœa and the heart was dilated one inch beyond the nipple to the left and one inch beyond the right border of the sternum to the right. Mr. MILNE endeavoured to bleed the patient, but no blood could be obtained from either median basilic vein. Even when the brachial artery was opened there was only a feeble trickle of dark blood. The cyanosis was well marked and the breathing was stertorous, while the heart was becoming more and more distended. He inserted a trocar and cannula into the heart in the fifth left intercostal space close to the border of the sternum. Blood of the colour of porter immediately flowed by the cannula. Twenty ounces of blood were removed; the cannula was then withdrawn and the puncture was closed by acupressure. The patient was much relieved, and there was only slight cyanosis; her strength, however, steadily failed and she died some four hours after the operation.

Surgery of the Blood-vessels.

Wounds of the larger blood-vessels, if untreated, are usually followed rapidly by a fatal termination. Mr. H. M. ANDERSON of Portsmouth has recorded a very striking case, in which the inferior vena cava was torn and yet the patient survived nine hours. A girl 7 years old was run over by a milk-cart an hour and a half before admission to the Royal Hospital, Portsmouth. The wheel had passed over the epigastrium. All the symptoms pointed to severe abdominal hæmorrhage and the child died nine hours after the accident. At the necropsy the abdominal cavity was found full of dark blood, and a tear was found in the inferior vena cava at the point where it pierces the diaphragm. The survival of nine hours with such a serious injury is remarkable.

Mr. G. GREY TURNER of Newcastle-upon-Tyne has recorded a somewhat important case. A boy, 4 years of age, swallowed a halfpenny, and though efforts were made to recover it by the introduction of the fingers. X rays were not employed and no instruments were introduced. For a day or two the child complained of pain about the pit of the stomach, but it soon disappeared, and for a couple of weeks the child had sore throat and difficulty in swallowing, but these symptoms also soon disappeared and a severe cough and dyspnœa came on Twenty-two months later he began to vomit blood. When he was admitted to the Newcastle Infirmary the X rays showed the coin lodged in the œsophagus, but as it was quite clear that some large vessel, almost certainly the aorta, had been opened by ulceration no attempt was made to remove it, and the child died the next day. At the necropsy the coin was found impacted in the œsophagus at the level of the crossing of the left bronchus, and the ulceration had extended into the aorta immediately beyond the origin of the left subclavian artery. Mr TURNER appended to his paper brief notes of five cases which he has seen during the last six years where death has been due to perforation of the aorta by foreign bodies.

The Treatment of Aortic Aneurysm

Aneurysm of the thoracic aorta is little amenable to treatment. Many methods have been devised, but it can hardly be said that any of them has been a real success. The most

recent method has been the introduction of a length of wire into the sac, followed by the passage of an electric current through the wire. A. A. ESHNER has collected 36 cases in which this treatment was adopted, and two of these were under his own care. He considers that in most of these cases the patient's life was prolonged and the symptoms were improved. The technique is fairly simple; some ten or twelve feet of gold or silver wire are introduced into the aneurysm through a hollow needle which is insulated except at its tip. The end of the wire is connected with the positive pole of a battery, the negative pole being placed on the back, and the current, which may reach a hundred milliampères, is passed through it for an hour and a half. In half the cases death followed within a month of the operation, but in one case the patient lived nearly twelve years. The method is naturally applicable only to sacculated aneurysms.

Aneurysmal Varix.

Sir HENRY MORRIS, in a clinical lecture, has described the first recognition of this important condition by Dr. WILLIAM HUNTER, and gave full references to other writers on the subject, while also describing a case which he saw in 1909 of this lesion. The patient was a girl, aged 7 years, whose leg had been punctured with scissors, and a typical aneurysmal varix developed. The case is remarkable both on account of the comparative rarity of the disease and especially the youth of the patient.

The Surgery of the Lymphatics.

Mr. W. SAMPSON HANDLEY took for the subject of his Hunterian Lecture at the Royal College of Surgeons of England the Surgery of the Lymphatic System, and that part of his lecture which was of special interest dealt with the "brawny arm" occurring in a certain percentage of cases of cancer of the breast. It had always previously been thought that this brawniness of the arm was caused by pressure on the axillary veins, but he showed that it was due to obstruction of the lymphatics. He went further, and devised an operation to relieve it, and this he called lymph-angioplasty. It consists in the introduction of silk threads into the subcutaneous tissue of the affected limb, and these serve as new lymphatic channels. Silk may lie embedded in the subcutaneous tissue for years with little alteration, and the practical results of his operation justify the attempt, for in several of the cases the relief has been great, and some other surgeons who have followed his procedure have met with a certain measure of success. We may therefore take it that the operation had become established as justifiable in the treatment of this serious condition.

Mr. A. B. MITCHELL of Belfast has also employed the method with success in cases of lymphatic œdema of the eyelids following erysipelas. Mr. HANDLEY has also, at the suggestion of Dr. ESSEX WYNTER, operated on cases of ascites by draining the fluid into the tissues through the femoral canal. Some of these cases were successful, but in others no benefit resulted. It is a little early to judge of the method.

Removal of Tonsils and Adenoids.

The operation for the removal of tonsils and adenoids is now widely performed by many general practitioners, and it is generally considered that the operation is comparatively safe. Dr. F. R. PACKARD, however, has recorded a case in which death followed the procedure. The patient was a girl, aged 2 years; she was anæsthetised with ether and both tonsils and adenoids were removed. No post-operative hæmorrhage occurred, but she died a few hours later and Dr. PACKARD regarded her death as due to status lymphaticus.

The hæmorrhage after removing the tonsils is occasionally very severe; even then it is usually controllable by pressure. Dr. H. H. GILPATRICK considers that firm and complete approximation of the anterior and posterior faucial pillars by means of sutures is the most efficient means of controlling the hæmorrhage, but the difficulty of the operation is so great that he recommends it only as a life-saving measure after other methods have failed. An interesting case has been described which was under the care of Dr. A. TENNYSON SMITH and Mr. HAROLD S. BARWELL. In this case the boy, aged 10 years, had constant bleeding after removal of the tonsils, and it was found necessary about a fortnight later to suture the pillars together. It was elicited after the first operation that the boy belonged to a family of bleeders, and that he had had severe hæmorrhage after circumcision in infancy.

The Operation for Cleft Palate.

A difference of opinion exists as to the best time for operating on cleft palate, most surgeons holding that it is best to wait till the patient has completed the first dentition before operation, while others maintain that the fissure should be closed well within the first year of life. Mr. T. H. KELLOCK has described two cases who had been operated on very early, but the result was unsatisfactory, and he insists strongly on the need for waiting till the child is older.

Other writers in our columns support this view and suggest the desirability of those who are in favour of the early operation exhibiting the cases in which it had been performed so as to show clearly the benefit obtained from the early interference.

Exophthalmic Goitre.

One of the most important subjects discussed in the Surgical Section of the British Medical Association at its London meeting was the Surgical Treatment of Exophthalmic Goitre, and the difficulty of arriving at a certain opinion is due in great part to the difficulty of deciding with certainty what patients should be put under this title. Some surgeons whose statistics show excellent results after operation certainly include many cases which would not be called exophthalmic goitre by others. On the whole, surgeons are more in favour of operative treatment than are physicians, but those cases seem most suitable for operation which are only slightly marked, and these appear to be just the cases which are likely to recover without operation. Dr. W. HALE WHITE in a recent address has reported the result of an examination into the after-history of the cases of exophthalmic goitre which were in Guy's Hospital during the years 1888 to 1907 inclusive. It was only possible to trace 54 of the 148 cases, and the result of the examination was to show that in a large proportion of the cases recovery followed, and the percentage of recovery did not seem to be increased by operation. He rightly lays stress on the very great importance of rest in the treatment of this condition.

Appendicitis.

Dr. DONALD W. C. HOOD has drawn attention to the tendency that appendicitis shows to become more virulent, and to the evidence that the disease may affect certain families, for many cases are known to occur in the same household. He holds that the disease is due to the effect of microbic influence and that the micro-organism may, under certain conditions, be conveyed from one individual to another, in other words he regards appendicitis as being contagious. Dr. ALFRED MANTLE maintains that appendicitis is not in itself contagious, but that the condition of mucous colitis, which is so often associated with it, may be more or less infectious. He considers that many cases which are diagnosed as appendicitis are merely examples of mucous colitis. Mr. ARTHUR H. BUCK advocates the very early operation in appendicitis. He is strongly of opinion that in every case of inflammatory appendicitis

diagnosed within the first 24 hours the appendix should be removed at the earliest possible moment, for he holds that the prognosis in any case of inflammatory appendicitis is absolutely uncertain, and only early removal can ensure success. With these opinions most surgeons will agree, for it is probable that if the appendix be removed within 24 hours of the commencement of the disease the mortality would be reduced to the smallest possible amount, but this cannot always be done, for the case may not be seen at so early a stage or permission to operate may be refused. Removal of the appendix in the "quiet period" will give good results; and Mr. W. H. BATTLE has analysed 400 cases of his own which were operated on by him at a time selected by himself, and among them there was none in which operation was required by the urgency of the attack. Of the whole series only one case died, and that death was due to acute peritonitis. Mr. BATTLE employs the method of temporary displacement of the rectus muscle which he suggested and performed for the first time 15 years ago, and which is generally called by his name. In 46 of the cases there was evidence of old perforation, and in four cases there had been obstruction of the bowels by adhesions.

In this country the rôle of an appendix in the causation of gastric symptoms is not much considered, though on the continent and in America the condition has obtained general recognition. Mr. HERBERT J. PATERSON has recorded 24 cases, in the majority of which operation was undertaken for a supposed gastric or duodenal ulcer. He describes the symptoms encountered, and he lays especial stress on the radiation downwards of the epigastric pain. Hæmatemesis and melæna may be present, periodical exacerbations of the symptoms occur, and a long history is generally present. The average duration of these 24 cases was six years. He attributes some of the failures of gastro-enterostomy performed for supposed ulcer to the circumstance that the symptoms were caused by appendicular disease.

Mr. C. A. MOORE of Bristol has recorded a case in which suppurative appendicitis coincided with perforated gastric ulcer. The patient was a girl, aged 18 years, who had suffered with symptoms of gastric ulcer, and she had also had several attacks of pain and tenderness in the right iliac fossa. She was suddenly seized with pain on the left side of the abdomen accompanied by vomiting, and 24 hours later she was admitted into hospital. Operation was performed the same evening and the appendix removed, but the condition of the appendix, which was inflamed, did not seem to be sufficient to explain all the symptoms; the abdomen was opened in the middle line above the umbilicus and much gas and fluid escaped. A perforation was found in the anterior wall of the stomach. This was sutured and the patient recovered.

Malignant Disease of the Appendix.

Sir T. LAUDER BRUNTON and Dr. LEWIS G. GLOVER have recorded an important case in which malignant disease of the appendix was treated with emanations of radium. Sir WILLIAM RAMSAY was the first to suggest the possibility of the emanations proving of value in disease, and Sir LAUDER BRUNTON mentioned the suggestion in 1904. The patient, who was a man 60 years old, had suffered from some diarrhœa and pain over the cæcum. On examination a small, long, tender swelling was felt and diagnosed as an enlarged appendix. The appendix was removed by Sir FREDERICK TREVES, and when examined microscopically it was found to be affected by a columnar-celled carcinoma. The patient remained well for two years, but recurrence occurred, and the tumour grew rapidly. The abdomen was opened by Mr. C. B. LOCKWOOD, but it was found that the growth was hard and irremoveable, and nothing was done. Injections of cinnamate of sodium had no effect. Then Sir LAUDER BRUNTON suggested the administration of the emanations of radium, and 1 cubic centimetre of water which had absorbed radium emanations for 10 days was injected into the subcutaneous tissue on two successive days. A few days later the swelling burst and much pus was discharged. In all 18 injections were given, 2 cubic centimetres of the emanation solution being injected every eight days. Rapid recovery followed, but a small swelling was left. Subsequently two other abscesses were opened, but fairly good health was enjoyed between the operations. Later, a short-circuiting operation was performed by Mr. J. BLAND-SUTTON, but the patient died shortly after. In this case, where the diagnosis seems to have been certain, for on several occasions portions of the growth were examined, the injection of radium emanations appears to have been of some benefit, at least sufficient to warrant its employment in other cases.

Ruptured Hydatid Cyst of the Abdomen.

Dr. J. E. BARLING and Dr. D. A. WELSH of Sydney contributed a paper on the Symptoms of Ruptured Abdominal Hydatid Cyst, based on six cases. The three distinctive signs are: First, eosinophilia; this is a common but not invariable sign in hydatid disease, but it appears to be constantly present in cases of ruptured hydatid; secondly, the presence of free fluid in the abdominal cavity due to peritonitis set up by the hydatid fluid; and thirdly, the appearance of urticaria. Of these the most constant are the blood reaction, and the presence of the peritoneal fluid. It is probable that the urticaria is constant, but it may be unnoticed by the patient. In cases in which free fluid in the abdominal cavity is the most salient clinical feature, the presence or absence of eosinophilia is of great diagnostic value.

Intestinal Obstruction.

We have published several accounts of instructive cases of intestinal obstruction. Dr. DAVID M. GREIG of Dundee has recorded a case of a boy, 12 years old, in whom symptoms of obstruction were caused by an enterolith which was spontaneously discharged through an umbilical fistula.

Dr. HENRY ROTH has reported a case in which signs of acute intestinal obstruction were produced by adhesions caused by the presence of pledgets of cotton wool found at operation in the peritoneal cavity. The woman confessed that an abortion had been induced on several occasions, and that the last of these was about six weeks before the onset of her illness. A hard patch could be felt on the posterior wall of the uterus, and this is probably where the uterus had been perforated and where the wool had escaped into the peritoneal cavity.

Mr. G. H. MAKINS has published a case in which obstruction of the bowel was caused by a Meckel's diverticulum. The patient was a boy of 20 who had signs of subacute obstruction, and when the abdomen was opened it was found that there was compression of a piece of bowel by a Meckel's diverticulum which was adherent near its tip. The diverticulum was removed and the patient recovered. A piece of a rib of a whiting was found in the diverticulum, perforating the wall.

Mr. REGINALD M. MOORE has reported a case of intestinal obstruction due to two distinct causes. The patient, a woman, aged 56 years, was admitted with a history of constipation and vomiting for three days. As a hard mass was felt by the rectum the abdomen was opened for the purpose of performing colostomy, and then it was found that a large subperitoneal fibroid had compressed the rectum, and it was removed. As, however, it was clear that the small bowel was more distended than the large intestine, search was made for the cause, and a Richter's hernia was discovered in the right internal inguinal ring; the bowel involved was gangrenous,

necessitating resection. The patient died from general peritonitis three days later.

Dr. N. I. SPRIGGS has published an account of seven cases of congenital intestinal obstruction. In all but one the obstruction was complete; the cases show that the site is most commonly in the lower ileum; the site next in order of frequency is the biliary papilla.

Mr. W. ARBUTHNOT LANE has described the changes which occur in the ileum as a consequence of the progressive descent of the cæcum into the pelvis as a result of chronic intestinal stasis. The ileum becomes sharply kinked about two inches from the ileo-cæcal valve. As the kinking is more marked when the abdominal wall is lax and tired, it follows that the pain is worse in the evening; it is also worse after meals and after riding or running.

Duodenal Ulcer.

Mr. B. G. A. MOYNIHAN read a valuable paper on Duodenal Ulcer before the Royal Society of Medicine, opening a discussion. He claims that the disease is more common than is imagined, and that it can be recognised by its symptoms. Immediately after a meal there is ease, and if pain or discomfort were present before, the meal relieves them and banishes them completely for a time. This group of symptoms is sufficient to justify a diagnosis of duodenal ulcer, and the diagnosis is confirmed at the operation. Mr. MOYNIHAN holds that when the diagnosis is certain surgical treatment is always indicated. The opponents of the idea that "hunger pain" is a sign of duodenal ulcer attribute it to "hyperchlorhydria," but the opinion advocated by Mr. MOYNIHAN is gaining ground.

Clamps in Gastro-enterostomy.

Mr. SINCLAIR WHITE reported a case of chronic duodenal ulcer in a man aged 26 years. He performed posterior gastro-jejunostomy, the usual clamps being employed. Death occurred from hæmorrhage from a vein in the stomach wall. This vein had not been secured by the stitches, and this fact was not recognised at the operation because the clamps employed prevented hæmorrhage until the inner row of stitches was completed, and then the hæmorrhage could not be seen. As this risk is always present when clamps are used, Mr. WHITE has discarded them, and a preliminary fast and careful packing with gauze make it possible to prevent contamination. This article evoked a number of communications from other surgeons, the majority of whom preferred to operate without clamps, but others considered that clamps could be so used as not to hide hæmorrhage. It is clear that good results can be obtained both with and without clamps, but if clamps are used they should not be so strong as to damage the tissues, and care should be taken that all hæmorrhage is arrested by the sutures.

A New Anastomosis Device.

Many surgeons have found the Murphy button of great value in intestinal anastomosis, but it has several objections, for it is liable to be retained for a long time within the body, as its shape is not favourable for passage along the bowel, and it may cause obstruction. Dr. F. W. FORBES-ROSS has devised an ingenious instrument for intestinal anastomosis which unites the bowel readily, and yet, from its shape, which is ovoid, it can pass easily along the bowel.

"606."

A powerful instrument has been placed in the hands of surgeons for the treatment of syphilis by the introduction by EHRLICH and HATA of the new arsenical compound, dioxydiamidoarsenobenzol, or "606" as it is generally called. A single injection of this substance in suitable dose has a marvellous power of causing the disappearance of syphilitic manifestations, the primary and the tertiary lesions disappearing even more quickly than the secondary. The Wassermann reaction usually becomes negative in a short time, and in most cases at least, no further signs are seen of the disease. THE LANCET has contained several important articles on "606," by Professor WECHSELMANN, Dr. JAMES MCINTOSH and Mr. PAUL FILDES, Mr. J. E. R. MCDONAGH, Fleet-Surgeon W. E. HOME, and Dr. W. D. E. EMERY. At the end of another year the value of the remedy will be more exactly known and its limitations will have been determined. Its claim to careful trial is established.

Device for Many Persons to See Operations.

The presence of many students and visitors is not so common in the operating theatre at the present time as it was some years ago, and, indeed, most modern operating theatres provide very little accommodation for visitors, and major operations are so common that even in large medical schools very few students beyond those who assist attend operations; yet it sometimes happens, from the rarity or importance of an operation, that a great many persons may wish to see it. For such a case a device which has been employed in New York City may prove useful; by this it is possible for spectators in a room adjoining the operating theatre to see clearly on a screen the whole operation, every move of the surgeon and of his assistant being plainly visible. There is no interference with the operator and no risk of infection. The method is certainly ingenious.

OBSTETRICS AND GYNÆCOLOGY.

The International Congress of Obstetrics and Gynæcology.

The fifth International Congress of Obstetrics and Gynæcology was held in St. Petersburg in September of this year and was well attended. The following delegates from Great Britain and Ireland were present at the Congress: Dr. AMAND J. ROUTH (London), representing the Royal College of Physicians of London, the Royal College of Surgeons of England, Charing Cross Hospital Medical School, and the Obstetrical and Gynæcological Section of the Royal Society of Medicine; Dr. THOMAS WILSON (Birmingham) and Dr. JERVOIS AARONS (London), representing the Royal Society of Medicine; Dr. EDWARD MALINS, representing the University of Birmingham; Sir ALEXANDER R. SIMPSON, representing the Edinburgh Obstetrical Society; and Mr. M. G. MCELLIGOTT, representing the Royal College of Surgeons in Ireland.

A large number of papers were read, many of the greatest importance, and the Congress was an undoubted success. The two most important subjects which were considered were Cæsarean section and the use of the vaginal route in the performance of various operations on the pelvic organs. On the first subject important papers were contributed by Professor BUMM, Professor PESTALOZZA, and Dr. AMAND ROUTH. The first discussed the advantages and disadvantages of the suprasymphysial section over the classical operation on the fundus of the uterus, and expressed the opinion that in aseptic cases the choice of method is not important. For feverish women with a septic genital canal neither method is secure, for the danger depends on the kind of infection, decomposition of the liquor amnii by ascending putrefactive germs being less dangerous than the presence of streptococci. Professor PESTALOZZI expressed the opinion that extra- and intra-peritoneal methods of Cæsarean section have each precise indications, the classical operation being always preferable where asepsis is certain. When this is uncertain the extraperitoneal operation should be performed, but in cases of certain infection embryotomy was indicated and no Cæsarean section was safe. Dr. AMAND ROUTH contributed a paper on Cæsarean Section in Great Britain and Ireland. He showed from statistics of all operations performed in the United Kingdom since 1867 how the lessened risk of Cæsarean

section had widened its range of usefulness, and considered it in the circumstances of obstruction to labour, uterine hæmorrhage, and constitutional crises.

A good deal of difference of opinion was expressed by the different speakers as to the merits of the extraperitoneal Cæsarean section, and there was by no means unanimity as to its employment in cases of suspected septic infection of the uterus. Professor SELLHEIM, for instance, maintained that in evidently infectious cases with a marked abnormal relationship between child and parturient canal all operative deliveries, with exception of the reduction in the size of the child, are dangerous. If this is so, then the utility of the operation appears to us to be small; and it must be remembered that not uncommonly there is a good deal of difficulty in the actual delivery of the fœtus—a very serious drawback to the procedure as compared with the classical Cæsarean section.

The vaginal route evidently finds considerable favour among Russian gynæcologists, since a number of papers were read before the Congress pointing out its advantages, more especially when combined with the use of the specula and lighting apparatus devised by Dr. OTT. With the use of these instruments some of the speakers maintained that tumours situated above the pelvic brim, even if complicated by adhesions, could be operated upon safely. We cannot, however, agree with the contention of some of the readers of papers, that cases of cancer of the uterus complicated by pregnancy are best dealt with by this route; and we are rather inclined to concur with the conclusions expressed by Dr. JAYLE, who considered that the vaginal route should be reserved for those cases only which were not suitable for abdominal section as a consequence of some exceptional conditions. At the same time, the many valuable papers which were read and the important discussions which took place cannot fail, when they appear in the proceedings of the Congress, to be of great assistance to gynæcologists and surgeons in enabling them to come to a correct conclusion on this point.

Musculature of the Pelvic Floor.

The muscles of the pelvic floor are of great importance in relation to the support of the pelvic viscera, and prolapse of these organs, especially of the uterus, is in nearly all cases associated with some loss of function of these structures. Even at the present day there is a good deal of difference of opinion as to which particular constituent of the pelvic floor—the fasciæ, muscles, or ligaments—forms the most important supports of the uterus, and the exact homologies of the various constituent muscles are still far from settled.

The whole subject has been treated very exhaustively during the past year by Dr. R. H. PARAMORE in his Hunterian lectures. Most anatomists are accustomed to regard the coccygeus muscle as directly related to the movements of the tail in the animals possessing such an organ; thus in tailed mammals these muscles are especially developed. Dr. PARAMORE, on the other hand, does not consider that the coccygeus and levator ani muscles are of much importance as tail movers, but he regards them as playing an important part in the maintenance of the intra-abdominal pressure. According to this view the development and evolution of these muscles is related to the requirements of the animal in regard to an increasing intra-abdominal pressure, and more particularly to the proper performance of respiration. Thus in ungulates, as he demonstrates, the pubo-coccygeus and ilio-coccygeus are entirely absent, and this, he thinks, is associated with the fact that these animals are often attacked and have to flee for their lives. The necessity, therefore, for a low abdominal pressure has led to the suppression of these muscles, while the non-development of the pubo-coccygeus further renders the act of defæcation during locomotion easy and its occurrence possible without interference with locomotion. On the other hand, in the carnivora, with their special adaptability for pursuing and killing, the development of these muscles renders it possible for the animal to fix, not only its thorax, but also its abdomen, and so enables it to execute certain muscular movements with greater certainty and a greater degree of force. According to the view taken by Dr. PARAMORE, these muscles play a much larger part than that of merely moving the tail, and their presence in man in a comparatively highly developed state is associated with the important physiological functions they are intended to subserve.

Cæsarean Section.

The problems connected with this operation have received a good deal of consideration during the past year, not only at the International Congress, but also in other places.

Before the Obstetrical and Gynæcological Section of the Royal Society of Medicine of London Dr. HENRY JELLETT read a paper on Cæsarean Section in the Treatment of Placenta Prævia, and came to the conclusion that there was no place for this operation in the modern treatment of uncomplicated cases of placenta prævia. In a few exceptional cases with a rigid cervix or premature rupture of the membranes, associated with an atonic condition of the uterus, it might be indicated, but his own preference in such a case would be for vaginal plugging, and if that failed for incision of the cervix and bipolar version. In the view that the performance of Cæsarean section was practically never indicated in the treatment of placenta prævia most of the speakers who took part in the discussion concurred.

At another meeting of the section Dr. F. J. MCCANN described a case of Cæsarean section for eclampsia with a successful result to the mother. The operation has been performed very few times in this country, and the author's contention that it was justified in certain well-defined cases met with little acceptance from the critics of the paper.

The justifiability of performing Cæsarean section in cases where it is indicated on account of pelvic contraction, but the patient has been long in labour and is possibly infected, is a problem which still waits a solution. It has been considered in various papers during the past year, and more especially in connexion with the alternative performance in some of these cases of pubiotomy or the extraperitoneal method of Cæsarean section. It is a difficult matter to determine with certainty whether in such conditions any given patient is infected or not. The period of time the membranes have been ruptured is, of course, no criterion, and the clinical recognition of the presence of sepsis may present great, indeed insuperable, difficulties. That the operation can be performed with success even many hours after the waters have broken is certain, but more definite information is required as to the presence or absence of any signs of septic infection in these cases. Without doubt the risk of practising this operation late in the second stage of labour has been somewhat exaggerated in the past, and the question requires further careful investigation.

The Causal Treatment of Dystocia in Cases of Pelvic Contraction.

The very excellent results obtained by Professor VON HERFF in the induction of premature labour by puncture of the membranes render his paper on this subject, read before the meeting of the British Medical Association, of great interest. In view of the considerable maternal mortality which still attends operations of pelvic section, together with the risks of injuries and subsequent complications, and a child mortality of 8 to 9 per cent., such operations, in his opinion, should be reserved as a last resource where the asepticism of

the case is too doubtful to admit of any other form of delivery.

If we compare the results obtained after induction of premature labour with those of pelvic section, given above, we find a maternal death-rate of not more than 0·5 per cent. and a fœtal death-rate, immediate and within the first two weeks of life, of about 20 per cent. Undoubtedly, then, this mode of treatment entails a risk to the child at least two or three times as great as that of pelvic section, but the risk to the mother cannot be compared, and it must be remembered that under the best conditions, such as obtain in private practice, the fœtal death-rate is much less than this. If the degree of pelvic contraction is too severe for the induction of premature labour, then Professor VON HERFF counsels the performance of an elective Cæsarean section with a fœtal death-rate of 7 per cent. and in carefully selected cases a maternal death-rate of some 2 to 3 per cent. While it is quite true that in a very large number of contracted pelves spontaneous labours will take place if the case is left to nature, yet this applies even more to cases where labour is induced, and with less resulting danger to the life and the health of the mother.

A study of the tables accompanying the paper demonstrates that the moderate conservative treatment of cases of contracted pelvis by the induction of premature labour gives at least as good results as the more radical method of awaiting delivery by spontaneous labour, and if this fails an ultimate recourse to pelvic section or to Cæsarean section. There can be no question, therefore, that, while in this country we continue rightly to consider the life of the mother as of greater value than that of the child, we shall continue to practise the induction of premature labour rather than have recourse to such operations as symphysiotomy or pubiotomy.

The Rational Puerperium.

The so-called rational treatment of the puerperium has been discussed during the year, but has made, we fancy, but little headway in this country. Indeed, some of its adherents do not appear so enthusiastic in its praise as they were; and we may well anticipate that the fashion of inducing parturient women to leave their beds as soon after the second or third day as they may feel inclined will not survive long when any large number of carefully recorded cases has been collected and studied. Apart from the danger of the development of displacements of the uterus or of subinvolution, it appears to us that the practice of keeping a patient in bed for at least ten days after her confinement in the case of the poor has many advantages. In their busy and hard-worked lives any opportunities of lying in bed, except on those occasions when they are suffering from some acute illness which necessitates their confinement to bed, are few and far between; and for this reason the short rest which the lying-in patient obtains after her confinement is undoubtedly beneficial. The advocates of early rising are prone to forget the strain which the nine months of pregnancy and the resulting labour entail even in the strongest and healthiest women, and the period of confinement to bed, short as it is, which such patients obtain when treated in the customary manner after their confinements must be of advantage to them, even if it is not absolutely essential to the complete and perfect recovery of their pelvic organs.

Adenomatosis Vaginæ.

It is not often that we can chronicle the discovery of a hitherto undescribed condition. This, however, is the claim made by Dr. VICTOR BONNEY and Mr. BRYDEN GLENDINING for a pathological state called by them adenomatosis vaginæ. In the case observed, a woman, aged 42 years, had suffered for 12 years from a persistent vaginal discharge of a transparent, sticky nature. The entire mucous surface of the vagina and portio vaginalis of the cervix was red and granular, being studded all over with small cysts, varying in size from that of a pin's head to that of a large pea. A continuous stream of mucous fluid like the white of an egg exuded from the diseased surface, in quantity about 6 ounces per diem, with a specific gravity of 1014. Microscopical examination of the vaginal wall revealed the presence of numerous glandular spaces lined by a single layer of tall columnar epithelium, actively mucinogenetic, as proved by their reaction to mucicarmine. Here and there the communication of these glands with the surface of the mucosa could be demonstrated. After a careful consideration of several possible explanations of this rare condition, Dr. BONNEY and Mr. GLENDINING came to the conclusion that a congenital peculiarity of the cells lining the vagina existed, in virtue of which they possessed facultative gland-forming powers similar to those possessed by the cells covering the vaginal cervix in immediate proximity to the external os uteri. This power had remained dormant until excited by inflammation or the effects of child-birth—a process analogous to that by which a glandular erosion of the cervix is formed.

Fibro-myomata of the Uterus and Pregnancy.

This subject is one of perennial interest to the obstetrician and to the gynæcologist, and is of great importance, because even at the present time there are two sharply defined schools who hold very divergent views upon the proper treatment to adopt in these cases. The one school—composed mainly of obstetricians, but including a number of gynæcologists—maintains, and, in our opinion, quite rightly, that the danger of this complication of pregnancy is grossly exaggerated. The other school—composed, we believe, almost wholly of gynæcologists—maintains strongly that the danger is very great and often sufficient to warrant immediate interference when the condition is first discovered, even if such interference necessitates the sacrifice of the life of the fœtus.

The subject was considered in a discussion at the meeting of the British Medical Association held this year in London, opened by Dr. WALTER W. H. TATE, who stated the case fairly and without exaggeration, and came to the following, in our opinion quite correct, conclusions as to the treatment of this complication. Dr. TATE said that the treatment of fibroids during pregnancy depended upon their situation, upon whether they would certainly, possibly, or certainly not, obstruct delivery. In the first case, if mobile, they might be pushed up above the pelvic brim; if too firmly impacted for this to be done without undue force, abdominal section and enucleation were safer; if there were no pressure symptoms it was better to wait till near term, and perform Cæsarean section and enucleation, or pan-hysterectomy. Small cervical fibroids and polypi might be removed per vaginam near the expected term. In the second group were included cases in which the fibroids were multiple and one or more of them encroached on the lower uterine segment. In such the speaker held an expectant attitude to be best for mother and child. In the third class the fibroids were entirely abdominal, and in the absence of severe symptoms he regarded operative interference as unwarrantable. Serious symptoms might compel interference, abdominal enucleation, or hysterectomy; enucleation was the operation of choice. The induction of abortion sacrificed the pregnancy and did not relieve the patient of her tumour; it was an improper proceeding.

The Operative Treatment of Prolapsus Uteri.

The large number of operations which have been devised by different surgeons for the cure or palliation of this condition is evidence of the uselessness of a great many of them. A very excellent paper—the more valuable since it gives the

after-history of a number of the cases, a very important factor in an attempt to gauge the value of any of these procedures—was published in our columns by Dr. J. B. HELLIER. In this he described his experience of WERTHEIM'S operation for prolapse, with fixation of the uterus in the anterior vaginal wall, so-called "interpositio uteri vesico-vaginalis." About 1000 cases have now been recorded by various operators, and in these a permanent cure was obtained in about 70 per cent., with relapse in some 30 per cent., including cases of relapse after subsequent childbirth. The proper performance of the operation requires the sterilisation of the patient, so that we can hardly accept these figures as strictly accurate. The operation is undoubtedly useful, and gives good results in selected cases. As we remarked, however, at the time, in commenting upon Dr. HELLIER'S paper, it is an operation not altogether free from risks, and has the disadvantage that in some of the cases the uterus is too small to keep up the cystocele. In other cases again it is too bulky to fit into place in the anterior vaginal wall and requires to be diminished in size—a necessity which undoubtedly increases the risk of the operation and involves the chance of severe hæmorrhage occurring. In spite, however, of these possible drawbacks, it is one of the best operations for this common complaint, and deserves to be practised to a greater extent in this country than it is at the present time.

OPHTHALMOLOGY.

During the past year no book of superlative value has been published. The Handbook of GRAEFE-SAEMISCH slowly and wearily wends its way towards a yet distant terminus. It outlives both its founders, and Professor HESS of Würzburg is now responsible for the completion of the vast second edition, taking the place of Professor SAEMISCH of Bonn, whose death is much deplored by ophthalmologists throughout the world. Of the parts more recently published, those dealing very exhaustively with exophthalmic goitre have already received some appreciation at our hands. When completed they will form a very valuable monograph on this disease. Of books published in the English language, Dr. THOMAS HENDERSON'S on Glaucoma is the most noteworthy. Founded upon a theory which will not find universal acceptance, at any rate in unmodified form, it predicates some revolutionary ideas which will at least prove stimulating to discussion, and it may be hoped also to further experimental research.

Colour Vision.

The now famous "TRATTLES" case—in which a man, stated to be dangerously colour-blind by the supreme scientific examiners of the Board of Trade, was found to be not dangerously colour-blind by an extraordinarily constituted legal court of inquiry—has led to the appointment of a Departmental Committee of the Board of Trade. The committee is instructed to inquire what degree of colour-blindness or defective form vision, in persons holding responsible positions at sea, causes them to be incompetent to discharge their duties; and to advise whether any, and if so what, alterations are desirable in the Board of Trade sight tests at present in force for persons serving or intending to serve in the Merchant Service or in fishing vessels, or in the way in which those tests are applied. The members of the committee are the Right Hon. ARTHUR H. DYKE ACLAND (chairman); Mr. RAYMOND BECK; Captain THOMAS GOLDING; Professor FRANCIS GOTCH, F.R.S.; Mr. NORMAN HILL; Mr. EDWARD NETTLESHIP, F.R.C.S.; Mr. J. HERBERT PARSONS, F.R.C.S.; Professor J. H. POYNTING, F.R.S.; the Lord RAYLEIGH, O.M., F.R.S.; Sir ARTHUR RÜCKER, F.R.S.; and Professor E. H. STARLING, F.R.S.; with Dr. WILLIAM WATSON, F.R.S., and Mr. S. G. TALLANTS as secretaries. Objections to the constitution of the committee have been brought forward by the Imperial Merchant Service Guild, the chief being that, understanding that shipping organisations were not to be represented and that the committee was to be a small one, the Guild took no steps to secure representation, but subsequently found that among those selected to constitute the committee one was the secretary of a large association of shipowners, another a well-known underwriter, while a third was an Elder Brother of Trinity House. The Guild was excluded from representation while the Royal Society was largely represented, the suggestion here being that the committee would be prejudiced in favour of the methods used by Sir WILLIAM ABNEY and recommended by the Royal Society. It may be hoped that the results of the inquiry will be so satisfactory as to disarm criticism, for the subject is one of great importance, full of difficult problems.

Glassworkers' Cataract.

The committee of the Royal Society appointed to investigate glassworkers' cataract has not yet reported, but we understand that much valuable research work is being carried out, both clinical and experimental. The latter involves abstruse physical and physiological investigations, which are in able hands and cannot fail to bear fruit.

Cataract.

Intracapsular extraction of cataract still occupies the most prominent place in the literature of the subject. Lieutenant-Colonel HENRY SMITH, I.M.S., like a modern ATHANASIUS, still fights the good fight of faith against many unbelievers but supported by firm adherents. The report of Major P. P. KILKELLY, I.M.S., on the results in 23 cases operated upon by Lieutenant-Colonel SMITH at Bombay during the Medical Congress is probably the strongest adverse criticism yet brought forward against the method. In five cases the capsule ruptured and in two vitreous was lost. The early visual results were not superior to those of ordinary extraction. In four of the five cases in which the capsule was ruptured the capsule became impacted in the wound. There was incarceration of iris in the wound in five cases. Vitreous opacities were found in nine cases, and in five of these iritis was present. Iritis also occurred in two other cases. Allowance must be made for the fact that Lieutenant-Colonel SMITH was operating in unfamiliar surroundings. Major KILKELLY concludes that "the average patient is exposed to an altogether unnecessary danger by the operation," but while most ophthalmologists will agree with him the other side is not without its arguments.

Post-operative infection is a subject of peculiar importance in relation to cataract extraction. Whilst ordinary pyogenic organisms like the pneumococcus are well known to cause panophthalmitis when introduced into the eye, and even saprophytes like the bacillus subtilis may produce a like result when introduced into the vitreous, it has hitherto been asserted by such an authority as AXENFELD that the staphylococcus albus is innocuous. HANCOCK, however, has proved this statement to be erroneous. In three cases of suppuration after cataract extraction a pure culture of this organism was recovered from the vitreous.

Glaucoma.

Much ingenuity has been directed during the past year to devising a satisfactory operation for ensuring permanent relief of increased tension in cases of chronic glaucoma. The operations already brought forward in some cases failed to appeal to ophthalmic surgeons as likely to attain this object without undue risk, and had therefore been abandoned, or in other cases were still on their trial. Among the latter must be included HEINE'S cyclodialysis, and the sclerectomies of LAGRANGE and HERBERT; amongst the former, the methods

of HERBERT and HOLTH for producing permanent incarceration of the iris as part of a glaucoma iridectomy. Most of the newer operations are founded upon the principle of establishing a permanently permeable cicatrix or "filtering scar." QUERENGHI, BJERRUM, and ABADIE have modified the anterior sclerotomy operation to this end, but few surgeons appear to have adopted their procedures. Cyclodialysis has been performed many times in many clinics during the last few years since the introduction of the method by HEINE. The operation is severe, liable to induce untoward results, and has not yet proved reliable in attaining the object aimed at. The reduction of tension is transitory, probably owing to fibrous union of the dislocated ciliary body to the sclerotic at no long interval after its operative release.

Greater success has been obtained with the various forms of anterior sclerectomy, and amongst these LAGRANGE'S operation has undoubtedly found most favour, both on account of its technical simplicity and the large measure of success in attaining the desired result. It differs from the ordinary glaucoma iridectomy a little more than the addition of a simple procedure, whereby a small portion of the sclerotic is snipped off from the anterior lip of the wound with scissors. In this manner firm fibrous union is impaired, and when successful the small gap is filled in with loose connective tissue, which permits the excess of aqueous to filter into the conjunctival lymph spaces, whence it is readily absorbed. HERBERT'S operation is more complicated, and appears to have been abandoned by its inventor in favour of a simpler operation, which will be referred to at a later stage.

The use of the trephine for the removal of a small disc of sclerotic has been advocated by FREELAND FERGUS and ELLIOTT, the principle being the same as in LAGRANGE'S and HERBERT'S operations. In ELLIOTT'S operation the opening is made into the extreme periphery of the anterior chamber and iridectomy is performed; it may, therefore, be regarded as a modification of LAGRANGE'S operation. In FERGUS'S operation the trephine is used more posteriorly, over the ciliary body, and an iris repositor is passed from the trephine hole into the anterior chamber, thus effecting a cyclodialysis. The operations were devised simultaneously and independently, and, as will be realised, are fundamentally different procedures. VERHOEFF'S sclerectomy resembles ELLIOTT'S except that the disc of sclero-cornea is removed by a specially devised punch or sclerectome, and only a small buttonhole is made in the periphery of the iris.

The most recent and probably the greatest advance which has yet been made, though the evidence is insufficient to demonstrate its utility, is the latest procedure advocated by HERBERT It consists of an anterior sclerotomy, so devised that a little flap of sclerotic is formed subconjunctivally. As the intra-ocular tension is restored after the operation the flap is lifted up somewhat, and in this manner firm union of the wound is impeded and spongy fibrous tissue permitting filtration is formed. The results hitherto obtained by this simple operation have been very gratifying, but it is still too early to assert that the great problem of the cure of chronic glaucoma has been solved.

In other directions the greatest advance in the problem of glaucoma is found in the invention of a reliable tonometer, whereby accurate numerical estimates of the intra-ocular tension have at last become possible clinically. Hitherto reliance has been placed upon the tactus eruditus of the surgeon, for the tonometers previously invented have failed in their object. The tonometer of SCHIÖTZ, however, bids fair to become an indispensable item in the ophthalmologist's armamentarium. It requires to be used with care and skill, and it entails some expenditure of time and trouble, but this is amply repaid by the accuracy and concordance of the readings. The instrument has been extensively used for some time in continental eye clinics, and is on its trial in this country. The reports hitherto obtained are uniformly favourable, and if they are substantiated, the acquisition of a reliable test of intra-ocular tension, to replace the uncertain clinical methods formerly in use, will prove a great boon.

Papillœdema.

A very able discussion of the pathogenesis of papillœdema, or "choked disc," due to intracranial tumours, &c., has been published by DE SCHWEINITZ and HOLLOWAY. This highly judicial review of the complex subject should be read by all neurologists and ophthalmologists. Time and experience have proved beyond dispute that blindness may be averted by prompt relief of intracranial pressure in these cases, even though the removal of the cause, such as a cerebral tumour, be impossible. The most important communication on this branch of the subject comes from Germany, in a paper by VON HIPPEL. His conclusions coincide with those now universally accepted in England.

Sir VICTOR HORSLEY adduces further evidence in favour of "ipsolaterality" of the papillœdema in cases of intracranial tumour—i.e., he strongly supports the localising value of the neuritis, holding the view that it commences first, and is usually most severe, in the eye of the same side as that on which the tumour is situated. He is of opinion that the papillœdema usually begins in the upper nasal quadrant of the disc.

Apropos of intracranial growths, BORDLEY and CUSHING have investigated the condition of the fields of vision for colours in these cases with interesting results. They find that the colour fields are often inverted and contracted, though there is no definite relationship between the contraction of the field for form and that for colours. Complete achromatopsia was noted in several cases, and hemiachromatopsia has occasionally been followed by complete homonymous hemianopia involving the same side.

Ophthalmia Neonatorum and Trachoma.

The necessity for notification of cases of ophthalmia neonatorum has been repeatedly dealt with recently in the columns of THE LANCET and the progress of the campaign reported upon. With regard to trachoma, interest has centred in the diagnostic significance of the so-called "trachoma bodies" of PROWACZEK and HALBERSTADT. Evidence has been brought forward by NOGUCHI and others to show that the bodies in question are not pathognomonic of trachoma, but may be found occasionally in ophthalmia neonatorum. They have been regarded as altered forms of the gonococcus. Considering the extreme difficulty of distinguishing these bodies with certainty from other intracellular granules possessed of similar staining reactions, their significance must be regarded as still *sub judice*.

Congenital Malformations.

Very valuable contributions to the explanation of many congenital malformations are contained in the Hunterian Lectures delivered this year by Mr. GEORGE COATS. He brings forward many ingenious suggestions based on the embryology of the eye, and at the same time accepts the view that some conditions, notably congenital anterior staphyloma, are due to the effects of intra-uterine inflammation.

Serum Diagnosis and Treatment.

WASSERMANN'S test for syphilis has proved of great value in diseases of the eye. Researches have been published by SCHUMACHER, COHEN, and others. Tuberculin treatment is now carried out frequently, particularly in cases of the more chronic forms of tuberculosis affecting the uveal tract and sclerotic. The results vary considerably, but this fact

is in a large degree explained by the great diagnostic difficulties.

Treatment.

Much attention has been devoted to the influence of X rays, radium, and ionisation upon various diseases of the eye. The subject must be regarded as still in the experimental stage, but some valuable results may yet be attained. Carbon dioxide snow has been introduced with success for the destruction of nævi and so on. New operative procedures for glaucoma and cataract have already been mentioned. ZIEGLER'S knife has been found useful for the division of dense membranes following the extraction of cataract, and for iridectomy in suitable cases.

DENTAL SURGERY.

Dentistry and School Children.

The subject which has attracted the most attention during the past year is that of the treatment of the teeth of the school children. So far but little has been done by the various educational authorities to carry out the work imposed upon them by the Act of 1907. The only effort, we believe, that has been made by the London authorities has been in the direction of approaching the present charities to ascertain how far the hospital authorities would be willing to undertake the treatment of children referred to them. In one instance—namely, at Poplar Hospital—an arrangement has been entered into which will secure the treatment of about 2500 children per annum, while a scheme for dental treatment at the Deptford Children's Centre has also been sanctioned by the Board. It is, we believe, the almost unanimous feeling of the dental surgeons attached to the London hospitals that it is inadvisable to attempt to deal with the problem through existing charities, and that the only right course is the formation of dental clinics under the direct supervision of the London County Council itself. The subject was dealt with in our issue of Oct. 1st, and it was there pointed out that inasmuch as the funds available will in all probability be insufficient for the work to be done as thoroughly as it should be done, the right course to pursue would be to employ the funds to produce the best results. The opinion we expressed was that the problem should be approached in the following order: (1) The thorough teaching of prevention to the parents; (2) the remedial treatment of the infants; and (3) the remedial treatment of the school children.

Periodontal Disease.

Several papers dealing with the subject of general periodontal disease have been published. In a contribution to THE LANCET[1] Mr. J. F. COLYER drew attention to certain points in this affection. He showed that the morbid anatomy of the disease suggested that the lesion in the bone was of the character of a rarefying osteitis. He drew attention to the fact that the clinical appearances are determined by the general condition of the patient, the resistance of the tissues, and the hygiene of the mouth. By a series of reproductions of photographs of the gum condition and radiographs he demonstrated that clinical appearances are not altogether satisfactory guides as to the extent of destruction of the bone of the tooth sockets.

The vaccine treatment of general periodontal disease was the theme of an interesting discussion before the Odontological Section of the Royal Society of Medicine.[2] The general trend of opinion seemed to be that the method of treatment required extended trial before any definite opinion could be given as to its value.

Effects of Nasal Obstruction.

In a paper by Dr. J. STODDART BARR[3] on the Effects of Nasal Obstruction during Childhood upon the Growth of the Teeth and Jaws, the author summarises his conclusions as follows: 1. That the changes are more rarely seen or much less marked in children under the age of 5 years. 2. That the most important causative factor is the lateral compression exercised upon the jaws as the result of the stretching of the cheek muscles consequent upon the mouth being constantly open. 3. That the direct contributory causes depending also upon mouth-breathing are: (*a*) lack of sufficient use of the jaws; (*b*) absence of the spreading action of one jaw upon the other, and the moulding action of the tongue; and (*c*) the short upper lip. 4. That the remote contributory causes which may play a part are hand-feeding, improper feeding-bottles, thumb-sucking, rickets, &c.

Dental Caries.

Mr. STANLEY P. MUMMERY,[4] in a paper on the Susceptibility of Teeth to Dental Caries, recounts some experiments undertaken to test the resisting power against lactic acid of different enamels. The teeth were suspended by silken threads in a solution of lactic acid 0·075 per cent., and with 100 teeth, the records of which are given, he found a very marked difference in the powers of resistance of the enamel.

In connexion with the subject of caries Mr. F. J. BENNETT records[5] an interesting series of experiments illustrating the action of fermenting milk on teeth. The experiments consisted in placing fragments of sound teeth in ordinary cow's milk and keeping them at a temperature of 35° C. The milk was changed at intervals—in some cases daily, in others after two or more days, up to a week. After varying periods he was able to produce a decalcification of the enamel and the dentine. Microscopical section of the dentine appropriately stained showed that micro-organisms had penetrated the dentinal tubes. The experiments are interesting and open up a wide field for research.

In a communication Mr. KENNETH GOADBY[6] deals with the question of the Buccal Secretions in Relation to Dental Caries. He states that organisms present in the mouth where caries is rampant invariably ferment glucose, lactose, and maltose, and occasionally cane sugar, but fermentation of cane sugar is more feeble and takes much longer than glucose or maltose. He suggests that, in addition to ordinary treatment, a change should be made in the flora of the mouth. For this purpose cultivations of some innocuous form of organism are made use of, such as B. mesentericus vulgaris or B. subtilis, and the spores of these are sown in the mouth or a lotion containing them is employed to rinse the mouth. The principle of the treatment advocated is to introduce organisms which do not ferment carbohydrate to acid, but which tend to produce an alkaline reaction and in addition by products inimical to acid fermentation.

Dr. KIRK has published some observations on the question of mucin, and he states that when there is an alkaline saliva loaded with mucin caries is usually very abundant. On the other hand, a clear acid saliva, free from mucin, is found in individuals who have very little caries. Now mucin is precipitated by acids, and when there is much mucin present in the alkaline saliva, acids formed locally in the mouth precipitate this mucin. Dr. KIRK has been able to show in a laboratory experiment that the mucin is thrown down by acids in the form of a film, and probably produces in the mouth one of the forms of plaque found on the teeth, this plaque consisting of felted masses of micro-organisms bound together by mucin. The mucin having been precipitated, the surrounding medium is acid, and decay may proceed readily beneath these films. This fact would seem to suggest that it is possible that a saliva of an alkaline reaction may

[2] Proceedings of the Royal Society of Medicine, Jan. 24th, 1910.
[3] British Dental Journal, May, 1910, p. 469.
[4] Proceedings of the Royal Society of Medicine, Odontological Section, Feb. 28th, 1910.
[5] Ibid., vol. iv., No. 1.
[6] Brit. Med. Jour., Sept. 17th, 1910.

be more likely to be present in cases of caries than an acid saliva. It is well known that bacteria will not grow at all readily in even a slightly acid medium, but require a neutral or slightly alkaline reaction in the culture medium. Thus it can readily be understood that—as was long ago pointed out by MILLER—the rapid proliferation of acid-producing organisms in an alkaline medium would give rise to a greater production of acid in the mouth in a given time than when the saliva was freely acid to start with.

Another communication as bearing upon the question of caries was published in the *British Dental Journal* by G. FRIEL. This observer examined 513 Kaffirs in Klipsprint Location. The conditions under which they lived approximated that of Europeans. In examining the teeth he was unable to use a probe, so that it is possible that the incidence of caries was greater than suggested. He found 1592 defective teeth, and, roughly speaking, 60 per cent. of the Kaffirs showed caries, the percentage of bad teeth being about 5.

In a paper on Drainage and Stagnation, Mr. J. G. TURNER[7] draws attention to the fact that dental disease is in the main due to the stagnation of food débris, &c., in and around the teeth, and that sufficient note is not taken of this by operators in their operations on the teeth.

Other Papers.

Mr. J. SEWELL ANDERSON gives a detailed account of a case of Facial Hemiatrophy,[8] in which the bones on the affected side were much smaller than those on the unaffected side, this being most marked in the case of the mandible, the difference being sharply defined at the symphysis. The necks and roots of the teeth on the affected side were also unduly exposed and loose. Another communication worthy of note is one by Mr. MONTAGU HOPSON, entitled "A Review of Some Modern Theories of Variation and Heredity, and Some Suggestions as to their Application to the Study of Orthodontia."[9] Mr. C. MANSELL MOULLIN, in a paper on the Essential Cause of Gastric and Duodenal Ulcer,[10] states that he is convinced that the real cause of the vomiting and hæmatemesis so often seen in young women is the persistent swallowing of septic toxins manufactured in the mouth and throat.

Under the title of "Two Odontoceles and Some Other Cysts,"[11] Mr. HOPEWELL-SMITH describes very fully two interesting cases of buried teeth associated with cyst formation. In the author's opinion the cysts met with in connexion with the jaws could with advantage be classified according to their pathological variations. He suggests the following: (1) Dental cysts; (2) eruption cysts; (3) follicular odontomes; (4) epithelial odontomes, or multilocular cystic tumours; (5) mucous cysts of the antrum; (6) odontoceles, (*a*) subcapsular, (*b*) extracapsular; and (7) cystic adenomata of the antrum and gum.

In a communication to the *Dental Cosmos*,[12] Professor A. MICHEL of Würzburg gives an extended account of his examination of the fæces of patients in relation to the digestion of starch and the masticatory apparatus. Briefly stated, he finds: 1. That persons with a sufficient number of teeth show starch present in the fæces if they are "bolters," and absent if they are masticators. 2. That in persons with an insufficient number of teeth the fæces contain more undigested starch in inverse ratio to the number of molars or premolars present. 3. That the introduction of dentures in cases where the masticatory apparatus is insufficient leads to a rapid diminution of the amount of starch in the fæces.

[12] Dental Cosmos, November, p. 1272.

Other interesting papers are: A Review of the Manufacture of Artificial Teeth,[13] by THOMAS GIBBONS; The Casting Process and its Use in Dentistry,[14] by J. T. W. DAVIE; and What Dentists have Contributed to Other Professions,[15] by B. J. CIGRAND. The problem of the articulation has been exhaustively dealt with by Dr. A. GYSI in a series of papers.[16]

Bibliography.

Amongst the new publications issued during the year the following may be mentioned:—"An Atlas of Dentistry in Stereoscopic Photos," edited by KARL WITZET; "Modern Dental Materia Medica, Pharmacology, and Therapeutics," by J. P. BUCKLEY; "Dental Surgery and Pathology," by J. F. COLYER, being the third edition of "Diseases and Injuries of the Teeth," by MORTON SMALE and J. F. COLYER; "Dental Surgery Notes," by E. B. DOWSETT; and "The Principles and Practice of Operative Dentistry," by J. L. MARSHALL (third edition).

ANÆSTHETICS.

General Anæsthetics (Inhalation).

While various new methods of employing general anæsthetics have been contrived by continental surgeons, the tendency in Great Britain has been to study the reputed dangers and shortcomings of the accepted methods, and rather to modify than to abandon the modes of procedure which have become established. It has been pointed out by the editor of the *Therapeutic Gazette* and other American writers that many of the dangers and difficulties, which continental surgeons appear to regard as inherent in the use of chloroform and ether when given by inhalation, are in fact due to the lack of experience of those who are called upon to employ them; since, while on the continent general anæsthetics are relegated to junior officers, in Great Britain practitioners of special knowledge and experience usually undertake the delicate duties of the anæsthetist. This fact has to be borne in mind when statistics of deaths and dangerous sequelæ are quoted to prove that inhalation anæsthesia is beset with exceptional perils. The newer methods, such as subdural stovainisation, intravenous and terminal arterial anæsthetisation, are committed to practised surgeons, and their results are comparable to those of the specialists in this country, who give anæsthetics by inhalation and whose results are, upon the whole, extremely favourable to this method of narcosis.

Choice of Anæsthetic.

The range of selection has greatly increased. Formerly it lay between chloroform and ether; whereas, at the present time, spinal and local analgesia, intravenous and intra-arterial local or general anæsthesia, and the use of scopolamine with morphine alone or antecedently to a general anæsthetic, have to be added to the list. Again, the prolonged use of nitrous oxide for general surgery synergetically to scopolamine and morphine, or with spinal or local anæsthesia, as well as a large number of mixtures of chloride of ethyl, ether, chloroform, have found advocates. The methods of using these agents are also considerably modified, and the selection of the method of using the agent or agents has become as much a matter of importance as the choice of the anæsthetic itself. Papers dealing with these subjects have appeared during the year.

A discussion on the Choice of the Anæsthetic was held in the Section of Anæsthetics of the Royal Society of Medicine,[1] which was opened by Dr. DUDLEY BUXTON, who discussed the subject under the heads of (1) condition of the patient;

(2) necessities of the operation, including the region involved; and (3) the duration of the operation. He favoured the use of chloroform following ether in all prolonged and suitable cases, and its employment in accurate volume percentages, together with oxygen. Dr. G. A. H. BARTON and Mrs. F. M. DICKINSON BERRY extolled the employment of ether by of the open method.

The Open Ether Method.

Mr. H. BELLAMY GARDNER read a paper before the Section of Anæsthetics of the British Medical Association on the open ether method.[2] For suitable cases he speaks in favour of the method. Lung affections he regards as contra-indications. Atropine (1-120th grain) is given before the administration, and morphine (1-6th grain) is added in the case of alcoholics and muscular subjects. The ether is dropped on 12 folds of gauze placed on a wire mask.

Dr. BARTON[3] has contributed a useful paper on this subject. Although advocating the plan, he admits objections—the length of the induction, the large amount of ether used, the difficulty of getting relaxation in muscular subjects, and for laparotomies. To meet these he suggests adopting the following plan. An inhaler is used which consists of a cylindrical chamber open at the top and having another opening about the junction of the middle and lower third communicating with the face-piece. This is lined with lint, so that the latter dips into the ether well, which is capable of holding two ounces. In this way a large evaporating surface for the ether is obtained. A Roth-Dräger type of face-piece with valves is employed, and simple adjustment permits the administrator to lessen or to increase the quantity of ether used. The C.E. mixture and chloride of ethyl, he suggests, may be employed before the ether is inhaled. Dr. BARTON, however, uses a few inspirations of chloroform vapour during the narcosis to promote anæsthesia in alcoholic and athletic persons; and relies upon morphine with scopolamine before the open ether method in laparotomies. Another "inhaler" suggested for the "open" ether method is described in THE LANCET of May 21st, p. 1421, by Dr. R. H. HODGSON.

Morphine and Scopolamine Narcosis.

A large number of papers dealing with the use of morphine and scopolamine with the open ether method have appeared, and the experience gained appears, upon the whole, to be favourable. Dr. CLIFFORD O. COLLINS[4] records 1100 cases in which these alkaloids were used. He regards the objections raised by TERRIER and others as unreal. Although he has used cactin synergetically he found it of little use. Ether given by a drop method has in his hands proved the best general anæsthetic to give subsequently to the scopolamine and morphine. He approves of giving repeated injections in the case of exophthalmic goitre, one being given the night before the operation is done. Children aged above eight years, in his experience, respond well to this method. This writer agrees with Dr. CRILE that nitrous oxide with oxygen, when employed after morphine and scopolamine, supply a valuable anæsthetic for major surgery.

Dr. CRILE[5] has compared the values of ether and nitrous oxide when used after scopolamine and morphine. Nitrous oxide, he thinks, causes less shock, less infection, and fewer after-effects such as nausea, vomiting, and headache. His conclusions are based upon experimental work, as well as 575 major operations carried out according to this method. Dr. CRILE has further elaborated a scheme which he describes as "stealing the thyroid," whereby a patient with exophthalmic goitre can be operated upon with the minimum of risk. Daily injections of scopolamine and morphine are made, while all suggestion of operation is avoided, and when the patient has become accustomed to this procedure she is wheeled into the operating-room and the general anæsthetic—nitrous oxide and oxygen—is given while the surgical condition is dealt with.

Dr. R. A. HATCHER[6] has contributed to the Council of Pharmacy and Chemistry of the American Medical Association an exhaustive report upon the action of scopolamine and morphine in narcosis and in childbirth. He regards the combination as valuable within limits, provided it is associated with some general anæsthetic, but he points out that in obstetrics it may increase the risk to the child. He supplies a valuable bibliography of the subject. A similar investigation undertaken by Dr. R. H. JAMIESON[7] gives experimental results which explain the clinical observations recorded by several surgeons upon the alarming retardation of respiration. Dr. JAMIESON states that artificial respiration restores animals whose breathing had dropped to five or six respirations per minute. RINNE[8] records two fatalities occurring within three days and due to scopolamine and morphine.

A somewhat unusual danger under this form of anæsthesia is reported by Dr. FAUST[9] of Berlin. The patient, a healthy youth, aged 17 years, developed violent spasm of the muscles of respiration with cyanosis. This occurred within an hour of the completion of appendectomy, and was so severe as to render the performance of artificial respiration impossible. The spasm passed off spontaneously but recurred six times subsequently; eventually the patient recovered. FAUST regards scopolamine as the cause of the spasm.

Dr. F. M. BARNES[10] of Baltimore has investigated the effects on metabolism of the scopolamine-morphine narcosis. When quantities are given sufficient to lessen the vital activities he found that a decrease of the absolute amounts of nearly all the normal urinary constituents occurred, while when scopolamine was given by itself there was increase of the vital activity and of the urinary constituents. These effects are transient and appear within 12 hours of the administration. Repeated doses of the drugs in combination, if given for a prolonged period, lead to the establishment of tolerance. The influence on metabolism, as shown by the variations in the urine, seems to arise through indirect or secondary action of the drugs. The delayed absorption in the alimentary tract is regarded as the primary cause of the urinary variations.

A considerable number of papers have appeared dealing with this combination in connexion with parturition. We may mention contributions by P. SICH,[11] and a review of the whole subject in the columns of the *Therapeutic Gazette* of Feb. 15th, which upon the whole speaks favourably of the plan, but would restrict its employment to hospital cases or those attended by a skilled nurse, as emergencies may arise which, if not promptly treated, may lead to serious results. Dr. TORRANCE THOMSON and Dr. DENNIS ATTERILL[12] have discussed the advantages of giving repeated small doses of scopolamine and morphine, while Dr. H. R. LAWRENCE[13] gives his experience of these drugs in obstetric practice in 126 cases. He had no maternal deaths, and the five deaths of the infants were, he thinks, not due to the scopolamine employed. 13·3 per cent. required resuscitation, while 73·3 per cent. are described as "lively," and 8·8 per cent. as drowsy. In 2·2 per cent. the mothers were unaffected;

in 17·7 per cent. they remembered, and in 82·2 per cent. they did not remember, the birth of the child. He thinks that when the infant is prejudicially affected it is the result of the morphine used. Although it remains an open question whether the labour is prolonged by these drugs, Dr. LAWRENCE is inclined to negative the suggestion.

The scopolamine and morphine sequence, besides being advocated for obstetric practice and as a preliminary to the use of a general anæsthetic, has found advocates among those who prefer to employ intrathecal injections of stovaine, tropacocaine, or other analgesic. It has been long recognised that nervous patients—and these form the bulk of those who have to face surgical operations—dread both taking the inhalation of a general anæsthetic and suffer severely also during prolonged manipulation under spinal analgesia. Dr. CRILE [14] has recently emphasised the danger of psychic shock especially in the case of persons suffering from Graves's disease. To meet this peril many surgeons have published their methods, which consist practically of the preliminary use of scopolamine and morphine. That this mind-shock is not a mere theoretical danger is shown by the experimental work of Dr. CRILE, which has demonstrated definite changes in the brain cells the result of fear.

Mr. A. E. JOHNSON [15] advocates the use of both intrathecal injection to block nerve influences provocative of shock, and a light general anæsthetic to obviate psychic influences. He asserts that "the combination of spinal and general anæsthesia is much more convenient and satisfactory." He points out that with a dosimetric method it is extremely easy to control the amount of chloroform if this anæsthetic is used, and to preserve an extremely light narcosis while ensuring a complete anæsthesia. A number of workers along these lines have adopted nitrous oxide gas or Hillischer's "Schlafgaz"—i.e., nitrous oxide and oxygen—as the general anæsthetic, using regional injections of stovaine or other local analgesic for nerve blocking. This plan Dr. CRILE advocated at the annual meeting of the British Medical Association.

NEU [16] employs scopolamine and morphine, and then maintains anæsthesia by a mixture of nitrous oxide and oxygen, employing a new form of apparatus, which he describes. Dr. S. BUNNELL [17] has extended the use of these agents to thoracic surgery. As a result of successful experiments upon the lower animals he claims that, given under positive pressure, the chest can be kept open for nearly two hours. Respiration and circulation can, he asserts, be kept going without difficulty, but so soon as the positive pressure is discontinued cyanosis, respiratory distress, and a vagal pulse develop, and death rapidly occurs.

Some diversity of opinion appears to exist among the advocates of scopolamine. While, upon the one hand, this drug is regarded as assisting in obtaining muscular relaxation, upon the other we are advised to omit scopolamine in abdominal surgery, as experience has convinced some surgeons that its use leads to muscular rigidity. Morphine with atropine should be substituted, it is alleged, when muscular relaxation is essential for the success of the operation.

Heart Massage.

An interesting case of cardiac failure under chloroform was reported by Dr. V. B. ORR [18] at the close of last year. The patient, a woman, aged 30 years, collapsed under chloroform. An abdominal incision was made and the heart, which was "flabby," was stroked from below the diaphragm. The woman made an excellent recovery. This case is recalled by others published by Captain T. C. RUTHERFOORD, I.M.S.,[19] and Mr. J. WALLACE MILNE.[20] Dr. ORR pointed out the three methods hitherto tried are: (1) the thoracic; (2) the subdiaphragmatic; and (3) the transdiaphragmatic. Two recoveries by the thoracic route have been recorded, but the method takes time and exposes the patient to serious unnecessary risks—e.g., pneumothorax. The transdiaphragmatic route has so far proved unsuccessful, so that the subdiaphragmatic is by most authorities regarded as the operation by election. Ten successes by this method are mentioned by Dr. ORR. The use of rubber gloves and the rapid sterilisation of the skin with tincture of iodine enable the surgeon, even if engaged upon a septic operation, to proceed to the laparotomy without loss of time, while pulmonary perflation with oxygen is carried out by the anæsthetist. In Captain RUTHERFOORD'S case the patient was a healthy adult native of India suffering from hæmorrhoids. The abdomen was opened and the heart was compressed 60 times a minute between the hands, one grasping it and one placed on the præcordium. The heart after 12 compressions hardened and resumed beating. Chloroform had been used. Mr. MILNE'S case was also a healthy male, and anæsthesia was produced in four minutes by chloroform. Comment upon this fact [21] suggests that the heart failure was due to over-dosage. The operation was for appendicitis. Incision to the left of the xiphoid cartilage allowed the entrance of the right hand which grasped the heart, the thumb being behind it. One squeeze initiated cardiac movement, and eventually the operation of appendectomy was successfully performed.

REHN [22] gives details of another case. A healthy boy, aged 7 years, collapsed while inhaling chloroform. Brauer's positive pressure apparatus was used to maintain respiration for two and a half hours, by which time complete restoration of respiration and circulation had occurred. The heart had been massaged by introducing the finger, but the pleura was unfortunately damaged and pneumothorax, which proved ultimately fatal, resulted so soon as the finger was withdrawn. The first heart movements were felt after 70 minutes and the beat was maintained for four hours. A useful tabulation of 50 cases is given by Dr. J. WHITE.[23]

Shock under Anæsthetics.

At the annual meeting of the British Medical Association a discussion of great interest took place upon this subject. Dr. CRILE advanced his well-known views with regard to the value of nerve blocking to protect the controlling centres from exhaustion. He pointed out, further, that both subarachnoidean injection and local analgesia fail to obviate psychic shock. To meet this he uses a general anæsthetic or scopolamine and morphine. Mr. JOHN MALCOLM, who does not regard as proven the theory of vaso-motor exhaustion being the cause of shock, advanced cogent arguments in support of what is now termed the acapnia hypothetical explanation of surgical shock.

We owe to Dr. YANDELL HENDERSON a mass of valuable experimental work supporting the view that when the blood has its content of carbon dioxide lowered to a certain point the symptoms of shock supervene.[24] Hyperpnœa leads to over lung ventilation, and when the carbon dioxide content is lowered the respiratory centre is no longer stimulated to act. Exposure of serous membranes also causes escape of CO_2 and leads to respiratory failure.

[24] Fatal Apnœa and the Shock Problem, Johns Hopkins Bulletin, August, 1910; and American Journal of Physiology, vol. xxiii.

The work of MOSSO, MISCHER, HALDANE, and the pupils of the latter, with the brilliant investigations of Dr. YANDELL HENDERSON, have advanced the theory of acapnia to a position of essential importance in relation to surgical shock under anæsthetics. Professor ERNEST STARLING and Dr. E. JERUSALEM[25] have also studied the subject experimentally, and their results are in accord with those of YANDELL HENDERSON. A further aspect of the matter of importance in anæsthetics is that it has been found by the last-named experimenter that after the oxygen supply of blood, of lungs, and of tissues has been exhausted, and this occurs in two or three minutes of apnœa, the asphyxia of the tissues leads to the appearance in the blood of the products of incomplete tissue combustion. This is, in fact, a kind of acidosis. The products in moderate amount stimulate the respiratory centre acting with the carbon dioxide. The practical view of the matter may be summed up in Dr. HENDERSON'S advice to treat cases of respiratory collapse by oxygen and carbon dioxide introduced by a laryngeal tube rather than by artificial respiration, and using as a preliminary an injection of morphine which hinders hyperpnœa and so increases the blood's supply of carbon dioxide.

Dr. H. H. BROWN[26] discusses post-operative shock. He considers that general anæsthetics, if properly used, lessen rather than increase the shock of an operation, and he supports his view by reference to recent work upon the general nervous system.

The Status Lymphaticus.

Lymphatism formed the subject of an important discussion before the Royal Society of Medicine.[27] Mr. H. BELLAMY GARDNER reviewed the cases and literature published, and a number of physicians, surgeons, and anæsthetists spoke. Dr. DUDLEY BUXTON'S[28] clinical lecture upon the status lymphaticus has appeared in our columns. The view he advances is that, so far as our knowledge at present warrants us to make a definite statement, this condition bears much the same relationship to the use of anæsthetics as does any other general state which depresses the vitality of the tissues of the body, and especially of the central nervous system.

Blood Pressure in Anæsthesia.

Mr. W. GUY, Dr. ALEXANDER GOODALL, and Dr. H. S. REID[29] have investigated this subject. They think the length of time of inhalation makes no difference in the case of nitrous oxide. Ethyl chloride in large doses depresses the blood pressure and produces cardiac inhibition. G. A. BUCKMASTER and J. A. GARDNER[30] record a further research on the action of chloroform and dealing with the gases of the blood under chloroform.

Anæsthesia by Colonic Absorption of Ether.

Dr. W. S. SUTTON[31] advocates rectal anæsthesia for operations about the head, neck, chest, larynx, and mouth. He deprecates its use in abdominal surgery and in emergency operations, since careful preparation of the bowel is essential for safety. His method is to introduce ether vapour by an apparatus he has devised, which allows warmed air or oxygen to pass through ether and vaporise, so that it enters the colon. The narcosis is commenced by oral inhalation.

Dr. J. H. CUNNINGHAM[32] gives a valuable *résumé* of the subject and describes his method. LEQUEU, MOREL, and VERLIAC state that cardiac and respiratory complications are liable to occur with this method. Collapse, they consider, is due to sudden yielding of the ileo-cæcal valve. This permits of a rush of ether vapour into the small bowel, leading to absorption and consequent over-dosage. By employing oral inhalation before the rectal tube is inserted the valve becomes relaxed and this danger is obviated.

Various Papers.

Papers dealing with the general principles of anæsthesia may be noted. Dr. R. H. GREENE[33] published a paper on the Surgeon's Responsibility in Anæsthesia. Dr. J. W. BOVÉE has pointed out that the Trendelenburg position lessens and may abrogate renal secretion, and hence increases risk in renal and in arterial disease. Dr. CRILE[34] has undertaken an experimental and clinical research on nitrous oxide and ether anæsthesia; and Dr. F. W. BANCROFT[35] reviews the present knowledge of nitrous oxide anæsthesia. Dr. F. W. HEWITT, M.V.O., in a paper contributed to our columns[36] deals with the subject of the Æsthetics of Anæsthetics. He contends that general anæsthesia is better for the patient than local or any analgesia which allows the patient's mind to be harassed by the environment of the operation; and that by judicious methods the passage into and from insensibility can be robbed of horror. The paper is replete with wise advice, and its theme is one too little considered by many.

Several useful papers dealing with the emergencies of anæsthesia have appeared. One on Fæcal Vomiting under Anæsthesia[37] (Dr. DUDLEY BUXTON) suggests a means whereby "fæcal drowning" can be obviated in serious cases. Acidosis is considered in relation to anæsthesia by Mr. F. H. WALLACE, and Mr. E. GILLESPIE[38] reviews accepted views upon acidosis as a cause of death from operations under anæsthesia.

Dosimetry in Chloroform.

The report[39] of the special Chloroform Committee of the British Medical Association has been presented to the profession, and its leading features formed the basis of a discussion upon the subject of dosimetry which took place on the opening day of the annual general meeting of the British Medical Association. The practical side of the question was introduced by Dr. DUDLEY BUXTON, while Dr. A. D. WALLER, F.R.S., spoke from the side of physiology. The report is too voluminous for us to do more than mention. It presents a historical survey of the subject, and physiological and clinical observations which demonstrate the effects of definite doses of chloroform upon the respiration, circulation, and organism as a whole.

Spinal Analgesia.

As has been pointed out above, many observers have become impressed by the danger attendant upon the patient's preserving consciousness during an operation. A considerable number of papers have been published which describe the merits of a combined method of spinal and general anæsthesia. Various writers have confirmed the view commonly expressed in this country that JONNESCO'S method of high injection is less safe than the lower site, and that the addition of strychnine does not abrogate the danger. A discussion upon the subject was opened by Dr. J. BLUMFELD during the annual general meeting of the British Medical Association, and the views expressed by the anæsthetists who spoke were rather in depreciation of this method, except under very exceptional

circumstances. Two deaths have been published in detail—one by Major GABBETT, I.M.S.,[40] who injected novocaine and strychnine in the interspace between the twelfth dorsal and first lumbar vertebræ; and the second by Mr. VICTOR MILWARD,[41] who also pursued JONNESCO'S method. Mr. MILWARD regards the death as due to the drugs employed.

Mr. H. T. GRAY has published his third series of 100 cases of spinal analgesia in children,[42] and gives a very fair presentation of the subject from his point of view. The advantages and drawbacks are carefully tabulated and appraised. Mr. GRAY'S papers form a valuable addition to our knowledge of this much-debated subject. THE LANCET (July 30th, p. 325) notes a "personal" experience—viz., of Captain J. DORGAN, R.A M.C. It is somewhat more favourable than that of a fellow officer who published his experience some time back in the journal of his corps. Dr. SPILLER and Dr. LEOPOLD[43] publish a report upon the action of stovaine upon the central nervous system. Although the research cannot be taken to apply in its entirety to the human being, it appears to indicate that there is danger in repeated injections, and that the brunt of the injury falls upon the motor tracts.

Intravascular Anæsthetisation.

In the Cameron lecture[44] Professor AUGUST BIER discussed local anæsthesia with special reference to vein anæsthesia. He points out the value and limitations of SCHLEICH'S infiltration method as elaborated by BRAUN, and eulogises the use of BRAUN'S isotonic solutions of novocaine and suprarenal extracts. Failure in this method is caused usually by not waiting long enough, half an hour at least being required. Other plans are HACKENBRUCH'S perineural injection, KROGIUS'S method of conductive anæsthesia, and CORNING'S and OBERST'S systems. Endoneural injection requires as severe an operation to produce anæsthesia as that for which it is merely an adjuvant method. The principle upon which vein anæsthesia is based is that the nerve trunks are surrounded by dense connective tissues which are hardly permeable to infiltration. If the analgesic is introduced into the circulation it readily enters and anæsthetises these structures and complete analgesia results. BIER describes his technique; he uses a Janet's syringe and glass cannula, with isotonic solution of novocaine 0·5 per cent., and 100 c.c. is the utmost quantity to be injected. It is essential to obtain ischæmia, to infiltrate and isolate a vein competent to hold the cannula. BIER distinguishes direct anæsthesia, which occurs in the area between the constricting bands, and indirect, which develops later in the tissues below the peripheral bandage. This is a regular conductive anæsthesia. The analgesia is brief and the addition of suprarenin did not remedy this. BIER considers the dangers of poisoning can be avoided if due attention is paid to his somewhat complicated technique and the quantity of the drug injected is strictly limited. He restricts the method to cases which cannot be treated by simple local anæsthesia. He has tried it in 244 cases.

HITZROT has suggested a modification of the plan BIER enunciated at the meeting of the German Surgical Society in 1909.[45]

Dr. J. L. RANSOHOFF[46] exposes an artery under infiltration anæsthesia, and ESMARCH'S strap is fastened some distance above the point to be injected and from 4 to 8 c.c. of 0·5 per cent. cocaine in normal saline solution are introduced into the blood stream. Although we are told the method is of great value, it obviously is not free from danger, and depends upon somewhat limited experimental data. It will be remembered that GOYANE suggested a similar plan in 1909.

Intravascular Injection of Ether or Chloroform.

BURKHARDT[47] has experimented and finds intravenous injection of chloroform causes hæmoglobinuria, but with 5 per cent. of ether in saline solution this is absent. 7 per cent. of ether, however, caused this complication. Thirty human beings were subjected to this treatment and without fatality. Several had the preliminary injection of scopolamine and morphine. H. KÜTTNER[48] has pursued this method in 23 cases. He cautions against the danger of thrombosis. Dr. R. GIANI[49] reports from Dr. DURANI'S clinic two cases of intravenous injection of chloroform. The injection was stopped when unconsciousness appeared and resumed when the patient evinced signs of returning sensation. Slight albuminuria followed. GOYANE[50] regards intra-arterial as superior to intravenous injection owing to the absence of valves in the arteries.

Local Analgesia.

Papers of interest have appeared by H. K. OFFENHAUS,[51] describing his method of performing operations upon the mouth and bones of the face under local analgesia, and by H. FISCHER[52] dealing with alypin, a drug which he appears to regard as one of the best of analgesics. A useful paper which summarises our knowledge of alypin appears in the *Therapeutic Gazette* for January last from the pen of Dr. F. M. FERNÁNDEZ. J. ROTHMANN[53] gives a useful account of the use of local analgesics in the routine work of general practitioners. K. MAYER[54] has adopted with success the plan in midwifery of cocainising the nose of women during labour pains. He also injects beside the dura and into the periosteum between the coccyx and sacrum. While alleviating their pains, it has never in his experience done any harm to mother or child. He avoids injecting the dural sac. Dr. F. H. MCMECHAN[55] discusses the anæsthesia for prostatectomy, and regards local injection in the perineum and suprapubic region as safest. BEVAN, however, while using a local analgesia, prefers to render the patient unconscious by means of nitrous oxide and oxygen.

That local analgesia is not without its perils is once more forced upon us by the account given by Captain A. D. JAMIESON, I.M.S.[56] In the course of an operation for urethral stricture a 10 per cent. solution of cocaine was injected. As the first injection failed to produce anæsthesia a second was made. The patient became convulsed and died.

Dr. BREWSTER ROGERS and Dr. HERTZLER have employed quinine and urea hydrochloride as a local analgesic, and regard them as equal to cocaine and to possess the property of conferring analgesia which persists for several days.

PUBLIC HEALTH.

The death of KING EDWARD VII., with all its far-reaching consequences, was an event of special significance in so far as preventive medicine is concerned. Although there is every reason to believe that our reigning monarch will take an interest equal with his father in all that appertains to the health of the people, the progress of hygiene and the development of administration during our late KING'S reign would

furnish material upon which an instructive volume might be written. Not only did this period mark a very great advance in the sanitary condition of the British Isles, but it also corresponded with a steady progress in tropical medicine and the application of fresh knowledge to the needs and circumstances of our colonial possessions.

We are as yet uncertain as to the precise form which memorials to our late KING will take in one or another part of Great Britain, but there are already indications that the furtherance of the sanatorium movement in certain counties will be one of them. And the interest which our present ruler took, as PRINCE OF WALES, in the subject of tuberculosis is sufficient to guarantee that his influence will always be exercised in the direction of assisting well-considered measures for the amelioration of the public health and the furtherance of scientific research.

Rat Plague in Suffolk and Elsewhere.

From a purely epidemiological and historical standpoint the event of the year 1910 has been the occurrence of what appears to have been a somewhat extensive epizootic of rat plague in parts of East Suffolk, accompanied, fortunately, by only a very few human cases. Our knowledge of rat plague in this country is not a very extensive one, and it is confined largely to the apparently limited outbreaks which have occurred from time to time at certain of our ports, such as London, Cardiff, Glasgow, and elsewhere. But so far as can be judged, the epizootics have disappeared, or, at any rate, have given rise to no further cases of human plague, after a few cases have manifested themselves and been dealt with promptly. It is, of course, not altogether impossible that the rodent malady may still exist in some of these localities in a chronic form, but as to this there seems to be no evidence, and, indeed, such evidence as there is is against such a view. But the work of the Indian Plague Commission has shown that in certain villages this chronic plague amongst rats does obtain in the off seasons, and that similarly at these times there are indications of the acute phase of the epizootic.

But these valuable Indian researches relate largely to the black rat (M. rattus), and not so much to the brown rat (M. decumanus), with which we have almost exclusively to deal in this country at the present time, and the difference between the habits of these two species is an all-important point in considering the relation of rat plague to human plague here in Great Britain. The black rat is, for the most part, a house rat, and, in fact, the report of the Indian Plague Commission speaks of it as almost "a domesticated animal," living and breeding, as it does, in the houses where the people live. Its nests are found in little-disturbed accumulations of material, such as stacks of firewood, cotton waste, &c., and in recesses such as cupboards. Moreover, in India the grain-supply of the house is stored on the premises, and articles of food, such as flour and potatoes, are easily accessible to the rats. The degree of infestation of the Indian dwellings by rats may perhaps best be gauged by the fact that the villagers commonly complain of having their sleep disturbed by the rats running over them, while the villages themselves are honeycombed with rat burrows ramifying in all directions. As, too, is well known, there is a great indifference amongst the natives of India as to the presence of rats in their homes, and they are said sometimes actually to protect the rats from molestation.

On the other hand, the brown rat (M. decumanus), with which we are now chiefly concerned in England, and which, of course, is also quite common in Bombay, lives mainly outside houses in the sewers, stables, granaries, hedgerows, stacks, and barns; and it is to this great difference that in all probability we owe our relative immunity to human plague in this country, even in the presence of an extensive rat-plague prevalence. And if this be so, our greatest efforts should be directed to keeping the rats out of our houses, partly by rendering them rat-proof and partly by removing from their vicinity all collections of refuse, grain, and other food which afford haunts for the rodents. There has within the last two months been apparently taking place in the affected corner of Suffolk a vast *experimentum crucis* in the destruction of an enormous rat population, a not inconsiderable proportion of which may have been plague infected, and yet, presumably, no human cases have occurred, even although it is to be assumed that large numbers of plague-infected fleas had opportunity of gaining access to the rat-catchers who were destroying their natural hosts. The explanation of this immunity of the rat-catcher is probably to be found in this fact, that a replete rat-fed flea does not take readily to the human host, and perhaps this may be more particularly the case with the Ceratophyllus fasciatus than with the P. cheopis, the black-rat flea. And there is also the additional fact that infection but very rarely follows the bite of a single rat flea. But whatever the explanation, the immunity of the rat-catchers is a reassuring circumstance.

At this time of year, however, too much reliance must not be placed upon this circumstance. Plague is a seasonal disease, depending primarily upon flea-prevalence, and it is possible that, with the ascending flea-wave of next year, there may be other human cases, and it is, therefore, at that time that renewed observation and rat destruction may be obligatory upon the local authorities. In the meantime, attention should be paid to the poorer properties in the invaded districts, not because there is much evidence that actual insanitation, in the ordinary acceptance of that term, appears to have very material relation to the presence of plague, but because it is the dilapidated houses of the poorest and dirtiest people which are most likely to be invaded by rats, and, it may be added, by fleas and bugs.

The Indian experience all points in this direction—i.e., that the incidence of the disease is less upon the well-to-do than upon the poorer population. The report of the Indian Commission is to the effect that Europeans are practically exempt; and the explanation of this relative immunity of the better-off is that as the people rise in the social scale they occupy houses of better structure, and their method of living approaches nearer to the European type. "The compounds of the houses are kept clean, and the household rubbish which accumulates is relegated to a godown, and there is less shelter or attraction for rats." Moreover, the well-to-do Indians live more like the Europeans and cease to regard the rat as a domesticated animal. In other words, in India the question of habit or custom is a determining one as regards immunity from plague. But, for all this, we must in no sense relax our efforts. Notwithstanding the statement of the Indian Commissioners that Europeans are practically exempt in India, we know that Europeans in this country and in others have within recent years suffered sufficiently heavily from plague. Rat destruction must be continued, and more especially must the greatest vigilance with respect to the discovery of dead or dying rats be exercised. The danger signal for human beings is the dead plague rat, and we must remark that the brown rat is highly susceptible to plague, and that the researches of TIDSWELL in Sydney have shown that the rat flea of this country (Ceratophyllus fasciatus) will, when starved, bite man. Similarly GAUTIER and RAYBAND showed in 1903 that plague could be communicated from rat to rat by this same flea.

Although it is a perfectly sound policy to continue to persevere with the destruction of rats which has been going on over such large areas, the fact should not

be lost sight of that there is abundant evidence to show that, even after the expenditure of a very large sum of money and steady application on an extensive scale, but little, if any, permanent effect is produced upon the rat population, so great is the fecundity of this rodent and so rapidly does it fill up its ranks in face of attempts to exterminate it. This has been the teaching of experience in Sydney over several years, and it would appear to be the lesson to be learnt from the Indian work. The greatest advantage is probably to be secured by vigorous action in actually infected localities or in localities where an outbreak of the disease is to be suspected.

The line of attack in the case of plague is not altogether unlike that which takes place in the cases of malaria or yellow fever—that is to say, the destruction of the breeding places of the several hosts. In the two latter cases no serious direct attempt is made to destroy the actual mosquitoes; the object is to destroy their breeding places and to keep them out of the houses. In the same fashion with rats, attempts to exterminate the species by setting up ring fences and undertaking wholesale slaughter can only be very partially successful, and on that account they must be carried on in conjunction with the removal of the breeding and feeding places of the animals, and by rendering our houses proof against their entry.

There should be little difficulty in this country in dealing with human cases should they occur—that is to say, unless our sanitary administration is a delusion and a snare. We have possibly become a little over-alarmed owing to the disease presenting itself in its worse—i.e., the pneumonic—form, the infectivity and fatality rate of which are sufficient to frighten the bravest. But we have the authority of the Indian Plague Commission to the effect that only 2·5 per cent. of all cases of plague are of this type, and that in other forms the disease is "not particularly infectious or contagious, and man-to-man infection plays no important part in the spread of epidemics in India." Multiple cases in invaded houses are, the Commission states, rare. But however all this may be in India, the disease in different countries may not behave in quite similar fashion, and here in this country we must rely upon a properly administered system of the notification of suspected cases. If all medical practitioners are sufficiently on the *qui vive*, provided that isolation, nursing, and observation accommodation are available, together with supplies of plague prophylactic, there would not appear to be ground for any undue apprehension. But it is idle to pretend that the situation is not an anxious one.

The Limitation of the Effects of Syphilis.

It may, perhaps, be said that this is a subject which belongs more to the domain of therapeutics than to that of prophylaxis; but, as a matter of fact, the two are in this instance so blended—as, indeed, they are in many other cases—that treatment must be regarded as largely preventive in its scope. It is not inconceivable that in years to come the sanitary authorities may be found to be supplying gratis the new syphilitic drugs, much in the same fashion as they now supply diphtheria antitoxin.

It is a matter of peculiar interest that a subject which, from the exclusively preventive aspect *viâ* the Contagious Diseases Acts, has been so vigorously and successfully opposed, should be in a fair way to be solved under the guise of treatment, unless the evidence at our disposal is worth much less than it appears on the surface to be. Over and over again has preventive medicine endeavoured to bring venereal disease within its administrative purview, but on each occasion public opinion has been too powerful. And now, a quarter of a century or more later, there comes "606," and with it the hope that the sequelæ of syphilis, amongst those who care to take advantage of science, may cease from seriously troubling civilised peoples. What is the actual lethal measure of syphilis cannot be accurately determined, but, as Professor OSLER showed in a lecture which we published not long since in our columns, the disease reaps annually an ever-abundant harvest. What is the veritable value of "606" may require time tests for its proof; but repeated trial is justified.

Enteric Fever Carriers.

Progress in our knowledge relative to the comparatively new danger which has now been added to enteric fever has been made during 1910, and the publication by the Local Government Board of a report by Dr. J. C. G. LEDINGHAM has focussed in useful fashion the present condition of the subject and furnished a full bibliography of it. This, together with the presidential address delivered before the Epidemiological Section of the Royal Society of Medicine by Dr. THEODORE THOMSON, should be read by all those who are anxious to assess the real influence of carrier cases in maintaining enteric fever prevalence. It must be admitted that we are still ignorant of the magnitude of this danger. Although it seems probable that some 2 to 3 per cent. of persons who have suffered from recognised attacks of enteric fever become carriers, and that possibly the proportion of carrier cases in the population as a whole may be as high as from 3 to 4 per 1000, we must await further investigation, more particularly in connexion with towns in which there have within recent years been extensive outbreaks of the disease, before we can even approximately assess the magnitude of the carrier's operations. Certainly, one of the most disturbing features in connexion with the subject is that persons who are never suspected to have suffered from the disease may nevertheless be found to be carriers. These carriers appear to be more common in adult life than in youth, and in the female than in the male sex. This is an unfortunate dispensation of nature, in that females are more commonly concerned with the preparation of food-stuffs than males, and there is only a very partial compensation in the fact that males are, perhaps, more than females engaged in the milking industry.

But the most disappointing circumstance in connexion with the research so far is the fact that no treatment—whether of drugs, vaccines, or operation—appears to be of permanent value. And this renders the circumstance that the movements of these carrriers cannot be largely controlled doubly deplorable. We are, therefore, left to rely upon the persuasive powers of our public health officials, and upon the practice of rigid cleanliness amongst such of our carriers as are engaged in the preparation of food or the drawing of milk. There is at least some comfort in the fact that GACHTENS has found that, after smearing the hands and fingers with fæces containing enteric fever bacilli, it was practicable by washing with soap and water alone, and even without subsequent drying of the hands, to cause a marked fall in the number of B. coli and B. typhosus. But if the hands were dried thoroughly after removal of the soap in running water the two organisms were found to have entirely disappeared. This method of hand washing is regarded as a fairly complete protection for ordinary persons, but those whose occupation entails the handling of food-stuffs are advised, in addition, to disinfect their hands in alcohol, either in the form of eau-de-Cologne or spirit of wine, both of which have been found satisfactory.

The Curative and Prophylactic Employment of Diphtheria Antitoxin.

We have on many occasions referred in our columns to the statements made in the annual reports of certain medical officers of health to the effect that children suffering from diphtheria not infrequently arrive at isolation hospitals, even

with the disease quite advanced, without their having been afforded the advantages of diphtheria antitoxin. We cannot understand these serious omissions. It is the obvious duty of every medical man, when he has reason to believe that he has to do with diphtheria, to explain emphatically to the parents what the proper treatment is. But we gather from the reports to which we have referred that this is by no means always done. The question of cost is, we suspect, responsible for this neglect in a certain proportion of cases, and with the object of removing this drawback many local authorities have for some years arranged to supply antitoxin gratis for the use of persons not in a position to pay for it. But even where this has been the case the provision has not, we understand, always been taken advantage of. But we are glad to see that the Local Government Board has now issued an Order, under Section 133 of the Public Health Act, 1875, and under Section 77 of the Public Health (London) Act, 1891, providing for a temporary supply of diphtheria antitoxin and of medical assistance in connexion with such supply. We note with satisfaction that the Order authorises sanitary authorities, or requires them at the direction of the Local Government Board, to pay to the medical officer of health a reasonable compensation for all action by him in executing the Order.

The Value of Isolation Hospitals.

There is still going on in the public health world a sort of mental rumination upon this interesting subject; and there is, perhaps, gradually approaching what may be termed a provisional crystallisation of thought in the direction of utilising these institutions more for selected cases of disease, notably scarlet fever, than as a means for the accommodation of every case in every district. There are also being carried out some instructive observations and experiments in reference to the "cubicle" and "cordon" system of isolation, with or without certain inunction processes. The first system is, of course, on the lines that were adopted now a good many years ago at the Pasteur Institute in Paris; the second system is a species of extension or modification of the first, based upon the belief that infection takes place exclusively by contact. There is also another modification in process, and that is the open-air treatment of the acute exanthemata, which is apparently being carried out with good results at Nottingham.

But, all these modifications notwithstanding, there is still pressing need for more isolation hospitals. Very few, if any, medical officers of health would claim that anything approaching proper isolation can be carried out in the homes of the poor in cases where there are many children; and, again, no responsible official would advise that the children should be kept at home in premises where milk or other foods are dealt with, or where clothing or similar materials likely to convey infection are handled. Greater efficiency in our smaller isolation hospitals is certainly called for, and the difficulty of securing adequate observation wards in the small hospitals, which single districts alone can usually afford, points to the expediency of providing well-equipped joint hospitals at convenient centres. In THE LANCET of Feb. 19th we drew attention to a valuable paper by Dr. F. G. CROOKSHANK in which, *inter alia*, he expressed the opinion that isolation hospitals remained "about the cheapest thing in practical insurance offered to the small ratepayer. ..... For about 5*s*. to 6*s*. a year it insures him against all expense in the event of his household becoming stricken with infectious disease, and safeguards him against business or professional loss." It is to be regretted that the average district councillor does not accept this view in practice.

The Control of Tuberculosis.

Distinct advance has been made during the past year in obtaining useful information as regards those cases of pulmonary tuberculosis which are in most need of help; and the new regulations which provide for the notification of all pauper cases should enable local authorities to put to the best use any arrangements they have made or accommodation which they possess, either for education or for treatment. The regulations are apparently being applied with discretion, and we have heard of no hardship being occasioned by their application.

The number of sanatoriums is being gradually increased, some of the new ones—such as that in process in Shropshire, and that which is contemplated and provided for at Ipswich—being in memory of our late monarch. Other sanatoriums, such as those of Westmorland and Durham, have made notable additions, the former having opened a home for advanced cases and the latter a separate institution for women.

There has been a good deal of critical discussion during the past year concerning the reliability of, and the inferences to be drawn from, sanatorium statistics. The discussion has not yet ended, but the criticism of the year has not been without its influence. In the first place, it is clear that more care and, we may add, candour are necessary in the presentation of these figures. All cases admitted, of whatever description, should be included; and all those cases should be followed up and accounted for year by year, the figures for each year being kept quite distinct from those of other years. It is a pity that the statistics year by year should in some instances lay themselves open to hostile criticism, and such criticism is inevitable so long as optimism is unduly strained after. It is contended by some that it is impossible to demonstrate the value of sanatoriums by statistics, because there are no reliable data relative to the duration of life of consumptive patients in pre-sanatorium times. To a large extent this is a matter of opinion, and the question really is whether such statistics as there are are properly comparable with sanatorium statistics of to-day. There are some observers who hold that many of the patients who now find their way into sanatoriums would in pre-sanatorium days never have been found to be tuberculous at all, unless possibly on the post-mortem table, and probably there is some truth in this view.

But although there may be differences of opinion with regard to the value of the statistics, there would appear to be little room for doubt that there is an almost unanimous opinion in the medical profession to the effect that the proper treatment for pulmonary tuberculosis is fresh air, abundant food, and medical control; and, this point being conceded, the only outstanding question is whether such treatment is best secured outside or inside what we call a sanatorium. The answer clearly depends upon the circumstances in any given case, but it may reasonably be contended that, when more or less continuous medical observation is necessary, there are economical and other advantages in favour of sanatoriums. It is clear, also, that the dwellers in towns cannot obtain the necessary fresh air or frequently a sufficiency of wholesome food in their own homes. In other words, this question of the value of sanatorium treatment cannot be fairly weighed up if this almost unanimous opinion of medical men as to their value is allowed to have no weight.

The Use of Isolation Hospitals for the Treatment and Education of Tuberculous Patients.

We are glad to see from the annual reports of medical officers of health that our fever hospitals, and more particularly our small-pox hospitals, are being in increasing degree utilised in non-epidemic times for the treatment and education of those who are suffering in various degrees from pulmonary tuberculosis. At first sight some dangers and inconveniences might be contemplated in connexion with a

practice such as this, but the somewhat extensive experience now available justifies the inference that, with the employment of reasonable and obvious precautions, no drawbacks whatever, except perhaps the sudden removal of the consumptive patients to their homes on the occurrence of small-pox or of an extensive outbreak of one of the other exanthemata, need be contemplated. And as to this drawback, it has to be observed that the tuberculous patients discharged would, on again reaching their homes, possess the great advantage not only of considerably better general health, but also of a full knowledge of how best to regulate their lives in future. The balance is clearly altogether in favour of this growing practice, and more particularly is this so with reference to small-pox hospitals, which, at any rate in past years, have remained practically untenanted for long periods together. The removal of the tuberculous patients on the occurrence of small-pox should occasion them no serious inconvenience, and, indeed, if such patients had been carefully revaccinated at a recent date, there would seem no reason why, if a separate building could be retained for them, they should not remain in the hospital.

The Better Control of Our Milk-supplies.

No comprehensive steps have been taken during 1910 with reference to the milk-supply of the country as a whole; but, nevertheless, certain of our large towns are doing some good work under the Model Milk Clauses, which are exerting a salutary effect upon the condition of the cowsheds and the cleanliness of milk for very many miles around each of the towns which possess the clauses in question. We drew attention in THE LANCET of Dec. 3rd last to recent action taken by Leeds under these model clauses. A milkman outside of Leeds, although supplying milk to Leeds, had failed to notify to the medical officer of health of Leeds the fact that his herd contained a cow with a tuberculous udder. But the power which is conferred by the clauses of examining in Leeds the milk supplied from outside had revealed the existence of tubercle bacilli in this supply. The farm was visited, the tuberculous cow found, and the milkman convicted. But although good work is no doubt being done in London and many other large towns, control in small urban districts and in rural districts which are outside the influence of the model clauses is often practically non-existent. The standard set by many rural district councils leaves the sanitary condition of the cowsheds much where it was 20 years ago. It seems doubtful whether much real progress will be made in these districts until administrative power in this particular is placed in the hands of county councils.

The Housing of the Working Classes Act, 1909.

So far as this extremely important measure is concerned, the year 1910 has been one largely of digestion and assimilation by local authorities of the numerous regulations which have been issued under its provision by the Local Government Board. The more the Act is studied the more complete seem the powers which it contains; and with the cordial coöperation of the local authorities and a sufficient driving power at Whitehall, the degree of wholesomeness and comfort in which the working classes live should be greatly enhanced. The regulations issued by the Local Government Board aim at systematising and enforcing in detailed fashion the routine inspection of dwellings, in order to discover and remedy the defects which, no doubt, exist in every sanitary district, but which are not sought out. A sufficiently broad view is taken in the regulations as to the discovery of defects which "may tend to render the dwelling-house dangerous or injurious to the health of an inhabitant," and it is this "tendency" which should be easy to translate into action. Several of our large towns have long since taken what may be termed town-planning action; but with the help of the new Act there should soon arise among our large towns wholesome suburbs in which, not only physical health, but also a measure of æsthetic enjoyment will be possible.

The Appointment of County Medical Officers of Health.

Certainly one of the most important provisions of the Housing and Town Planning Act is that contained in Section 68 of Part III., whereby it becomes compulsory on the part of county councils to appoint a county medical officer of health under Section 17 of the Local Government Act, 1888, and we are glad to see that the counties which had not already made their appointments are gradually falling into line. But there is nevertheless, it seems to us, if the best administrative results are to be obtained, need for selecting officers who are, in the first place, public health specialists rather than school medical officers alone, without experience in sanitary administration, and who may have only quite recently obtained the necessary diploma. It is of great importance that those who are called upon to some extent to supervise the work of, and to give advice to, district medical officers of health should be persons who possess some additional claim to do so than the mere possession of a diploma in public health, which may have been possessed by some of the district medical officers for many years.

The Appointment and Duties of Medical Officers of Health.

What was practically the last administrative act on the part of the Central Health Department was the issue of a new general Order relative to the appointment and duties of sanitary officers outside the metropolis. We shall notice the Order more in detail shortly, but we may here mention that it modifies previous Orders in certain important particulars. Its general tendency is in the direction of ensuring permanency of office, for appointments can now be made without limit of time, and in place of automatic lapsing of appointments automatic re-election will occur. The whole-time appointment is encouraged by pointing out that the officers in question may conveniently hold the appointments of police surgeon, public vaccinator, district medical officer, and medical officer of the workhouse, as well as that of certifying factory surgeon. Moreover, a whole-time officer might supplement his income by the examination of water and by acting as consultant in cases of infectious disease. We are glad to see, too, that in the opinion of the Central Department the medical officer of health should be more generally recognised as the official head of the public health department, and that the sanitary inspectors should act under his supervision.

The Conservation of Child Life.

The valuable report made in the early part of the closing year by Dr. ARTHUR NEWSHOLME, principal medical officer of the Local Government Board, upon infant and child mortality, raised several extremely interesting issues which we noticed under the above title in THE LANCET of August 6th. The author of the report showed that infantile diarrhœa, which is such a potent factor in promotion of excessive infantile mortality, is brought about largely by strictly preventable conditions, and more particularly by those phases of defective sanitation which are connected with the conservancy system of excrement disposal, inefficient scavenging and unpaved yards. This appalling infantile mortality, which all of us deplore, can, he concludes, be most effectually diminished by efficient domestic and municipal sanitation and good housing, coupled with that very essential factor, intelligent and painstaking "mothering." Dr. NEWSHOLME appealed to certain counties wherein the infantile mortality-rate is still tremendous to awake to their responsibilities as, in the words of Sir JOHN SIMON, "the appointed guardians of masses of human beings whose lives are at stake in the business"; and he dwelt with emphasis

upon the necessity of removing the low stage of civilisation in which such a large section of the community in some of these counties live. Public health and preventive medicine are largely matters of social circumstances, and until some higher standard of excrement disposal is reached than obtains in some of our large northern towns, we agree with Dr. NEWSHOLME that, in a sense, the people must be regarded as living in a condition of "insanitary barbarism"—for such these conservancy methods must appear to those who have lived under the wholesomeness of a water-carriage system.

The Medical Inspection and Treatment of School Children.

We have dealt with this subject so often and so recently[1] in the pages of THE LANCET—both in the form of leading articles and of notices of many of the annual reports of school medical officers—that we shall not refer to it at any length at the present moment. The annual reports separately considered, and the recent report of Dr. GEORGE NEWMAN, the principal medical officer of the Board of Education, alike show the very encouraging progress which is being made both in inspection, in the sanitary condition of the schools and playgrounds, and in the treatment of the long roll of defects which is being unfolded. As regards this very difficult subject of treatment, it is clear that more and more advantage is being taken daily of existing agencies by the process now very generally adopted of following up the cases by the aid of all the agencies, medical and lay, which can be invoked towards this end. We learn from Dr. NEWMAN'S report that out of 314 educational areas in which school medical officers have been recognised the medical officer of health has been selected for the post in 230 cases, while in the remainder arrangements have in nearly all cases been made for proper coöperation between the officers in question. Another gratifying feature in relation to the future progress of both inspection and treatment is the cordial manner in which voluntary bodies are lending their aid. In this country we can do very little without the willing assistance of the public, and it speaks volumes for the tact displayed by the school medical officers and their assistants that the teachers are coöperating so willingly, and that the parents in increasing degree are entering into the spirit of this great social reform. The machinery in London for the medical inspection and treatment of school children does not yet work smoothly, and the metropolis lags behind.

The Neglect of Vaccination.

Difficult as it may be to believe in this, the land of JENNER, it seems probable that, given no great outbreak of small-pox, England will before many years are over consist of a practically unvaccinated community, a condition of things which cannot be contemplated without a feeling of the greatest anxiety. But even short of this prospective unprotected population we have now in reality an adult population which, in the absence of compulsory revaccination, is already very largely unprotected; while as regards the children no insignificant number of the nominally vaccinated are but very imperfectly protected against small-pox. One-mark vaccination is proceeding apace, and with it is decreasing the degree of our national security.

It is, we are aware, contended, and with a measure of truth, that our sanitary administration has now reached such a degree of efficiency that—with the notification of cases of small-pox and, in threatened periods, varicella too, and with our arrangements for vaccinating contacts, searching out unrecognised cases, and isolating such cases as occur—we have little to fear. But the recent experience of Bristol shows us the enormous difficulty of following up all the exposed persons, even with a well-equipped establishment. Thus we cannot but view with serious misgivings the behaviour of small-pox in the places where our sanitary organisation is little other than nominal, and where neither the medical officer of health nor sanitary inspector possesses much experience or special training in health matters. It is apparent from the numerous comments contained in the annual reports of medical officers of health that they are feeling considerable anxiety with regard to the future.

The Purification of River Water.

To those who procure their drinking water from deep wells and upland surfaces far removed from human habitations this subject has but little practical interest. But to the 6,000,000 people who dwell in and around the metropolis, and who drink the purified drainage of the Thames Valley, it is a matter of great comfort to find that the further researches of Dr. A. C. HOUSTON, the Director of Water Examinations at the Metropolitan Water Board, fully bear out his former conclusions as to the great value of water storage as a means of bringing about the destruction of pathogenic organisms prior to the river water being turned into the filters. This discovery concerns not only London but also certain other English towns, and it will be necessary to impress upon all river-drinking communities the necessity for the provision of adequate storage accommodation. Those of us who have followed the history of water-borne epidemics of enteric fever and cholera and the risks which attend filtration will still hesitate to advise the use of river water as potable, but it must be said that recent work with reference to the lethal point of pathogenic organisms, together with the experience of London during the last 30 years, are tending somewhat to modify current opinion on the subject of river water.

EXOTIC AND TROPICAL DISEASES.

The public interest in exotic and tropical diseases has shown no abatement during the past year, and it is an encouraging sign to find that a proposal has been made in the London press from an influential quarter that London's memorial to our late KING should take the form of a "King Edward VII. Tropical Research Fund," the interest from which should be devoted to carrying out and extending research work on tropical diseases. Among the public men who have expressed their approval of the proposal may be mentioned Lord NORTHCOTE, the Marquis of NORTHAMPTON, the Earl of ELGIN, the Earl of CREWE, Lord ROTHSCHILD, Lord KITCHENER, the Right Hon. JOSEPH CHAMBERLAIN, and Mr. RAMSAY MACDONALD, M.P.

The past year has been marked by a considerable extension and diffusion of exotic disease in various parts of the globe, and there are some indications that cholera and plague may in the coming year spread in certain portions of Europe and may even threaten our own land. Yellow fever, too, has displayed increased activity in those places where modern methods for controlling it have not been applied; and in these countries, if the next season be favourable, we may look for epidemics of some severity. As in former years, we give below a brief account of the occurrences throughout the world of these three principal exotic diseases, and so far as limits of space will allow, we add a few comments upon some of the other diseases which belong to the exotic or tropical class.

Cholera in Russia.

In 1910, for the fourth year in succession, cholera was epidemic in Russia, the outbreak proving the most serious that has occurred since 1892, when over 300,000 persons were attacked, and more than 150,000 of them died from the disease. Up to the end of November of the present year the number of cholera cases actually reported in the 11 months

[1] THE LANCET, Dec. 3rd, 1910.

amounted to nearly 216,000, and of these more than 100,000 proved fatal. By the beginning of December the epidemic in Russia had for the time being practically died out.

In 1910, as in the previous three years, St. Petersburg had its cholera epidemic. So far as can be ascertained, some 4500 persons were attacked, and of these about 1700 lost their lives. Cronstadt, Riga, and other ports in the Baltic were also invaded. Only a few imported cases were reported in Finland. Notwithstanding repeated importation of infection into Poland, there was no severe epidemic. It was, however, especially in Southern Russia, that the severity of the 1910 outbreak was experienced. Many of the grain ports along the shores of the Black Sea and the Sea of Azov were invaded, including Odessa, Theodosia, Kherson, Kieff, Kertch, Mariupol, Taganrog, Nicolaieff, Rostov-on-Don, Batoum, Poti, Novorossisk, and others. When the infection spread to the industrial districts in the South of Russia a panic followed, and thousands of the people fled from their infected towns and villages, carrying with them the germs of the disease and conveying them to other localities. The coal mines and the blast furnaces ceased to be worked, and many persons engaged in these and other industries were thrown out of work, adding greatly to the difficulties of the situation by the poverty and famine which resulted. The Russian Government, on the nomination of the Red Cross Society, despatched Professor G. REIN, Privy Councillor and President of the Medical Council, to the invaded provinces to direct measures for controlling the epidemic. With the advent of cooler weather the severity of the epidemic abated, and by December, as has been said, the disease had practically disappeared.

The Asiatic provinces of Russia were also affected by the cholera prevalence, which extended even as far as the Transbaikal Province, Eastern Siberia, and Vladivostock on the Sea of Japan. It is more than probable that the disease will reappear in Russia next summer. The sanitary condition of Russia is in many places deplorable, and affords favourable opportunities for the spread of cholera and other epidemic diseases.

Cholera in Europe, Outside Russia, and in North Africa.

Russia acted in 1910 as the chief diffusing centre of cholera for the rest of Europe. The infection was carried across the land frontier into Germany, groups of cases due to this importation of Russian infection being noted at Spandau and Ruhleben, near Berlin, at Marienburg and Kalthoff in West Prussia, and at Freiburg in Hanover, near the mouth of the Elbe, 50 miles below Hamburg. Cholera was also conveyed across the land frontier into Austro-Hungary, cases being reported in Austria at Vienna, Trieste, and Laibach; while in Hungary, Budapest and a number of the provinces were affected; altogether up to the middle of November over 400 cases had been notified. Groups of cases, too, were reported in Roumania, Servia, and Bulgaria. Cholera was also carried by ships to French, Italian, Swedish, Norwegian, Danish, and Dutch ports; and in the persons of Russian emigrants was taken across the Atlantic to American ports, both north and south. But in none of these instances, save one, did an epidemic result; this exception was Italy.

From a Russian port in the Black Sea cholera was carried by some gypsies on board a ship to the shores of the Adriatic, and not long after the landing of these passengers the disease became epidemic in the provinces of Bari and Foggia in the south-east of the Italian peninsula. Fugitives from these districts carried the infection to Naples and other places in the South of Italy, whence the disease spread to Sicily and Sardinia. The authorities seem to have been slow to admit the presence of the disease. In Naples, for example, for about a month cases of cholera were officially certified as gastro-enteritis. The Italian provinces invaded by cholera in 1910, besides Bari and Foggia, included Naples, Rome, Salerno, Avellino, Campobasso, Caserta, Caltanisetta, Lecce, Perugia, Sassari in Sardinia, and Palermo, Messina, Girgenti, and Trapani in Sicily, though in some of these provinces only a few cases occurred. Up to the end of November about 1600 cases and rather more than 800 deaths had been certified in Italy from cholera. This probably is an under-stating of the amount. The whole of the northern portion of the kingdom remained free, except for the occurrence of one or two ship-borne cases at the port of Genoa. The sanitary circumstances of some parts of Southern Italy are generally unsatisfactory, and cholera, if introduced, finds little difficulty in spreading. It is feared that a recrudescence of the disease may occur in the coming year as soon as the weather conditions become more favourable for its spread.

From Naples cholera was carried to Tripoli in Barbary, North Africa, where a considerable epidemic occurred during October and November. From Tripoli the disease was conveyed into Tunisia, cases occurring on the island of Jerba, off the coast. Towards the end of November the appearance of cholera in Madeira at Funchal, the capital of the island, was officially declared, some 650 cases having been notified in about three weeks. How cholera reached Madeira has not yet been ascertained, but it appears that at the end of October an illness was prevalent to which the Portuguese medical officer of health gave the name of "*gastro-enterite in facto contagioso*," and this was thought by some to be a form of enteric fever. By request a bacteriological expert was sent out by the Portuguese Government from Lisbon, with the result that cholera was diagnosed.

Cholera in Turkey and Persia.

From the Russian provinces south of the Caucasus cholera was carried across the frontier into Turkish territory, invading the vilayets of Van and Erzeroum during July, and appearing later in the vilayet of Mamouret-ul-Aziz. Coming westwards, cholera reached Trebizond in September, causing a considerable epidemic, some 650 persons being attacked up to the middle of December. The port of Zungulduk, on the Black Sea, was also invaded, and later the infection spread along the shores of the Bosphorus, different districts of Pera, Galata, and Stamboul becoming involved. Ultimately the country in and around Constantinople was infected, and during October cholera became epidemic among the garrison as well as among the civil population. Troops returning by sea from the autumn manœuvres were attacked upon the transports and the sufferers were landed at Touzla, in the Gulf of Ismidt, where up to Oct. 30th 250 cases had been treated in the lazaret. Other outbreaks were reported at Samsoun, Tizirk, Beirût, Bigha, Rhodes, Salonica, Adrianople, Eregli, Rodosto, Philippolis, and Charchamba.

In October cholera was prevalent in Basra and Bagdad, as well as in the districts of Mesopotamia. There was a cholera epidemic at Muscat, in the sultanate of Oman, during September. In August cholera appeared in Persia, having been conveyed across the Caspian Sea from Baku and other Russian ports. Epidemics were subsequently reported at Ardebil, Enzeli, Sorab, Kermenshah, Badjguiran, Resht, Turbat, Haidari, Hamadan, and other places. A few cases also came under observation in November at Mohammerah, a Persian port at the head of the Gulf.

There has been a smart epidemic of cholera in Funchal and other parts of Madeira, which has taxed the resources of the resident authorities and medical men.

Cholera in India and the Far East.

Cholera, as in most years, was prevalent during 1910 in a number of the provinces of India, more particularly in the Presidency of Bengal, the United Provinces of Agra and

Oudh, and in Eastern Bengal and Assam. A sharp local outbreak occurred in June in Kashmir, where the infection extended from the native population to the military, including among its victims at least three British officers belonging to the garrison. Only a few cases appeared in Ceylon at Colombo; in two instances the infection was ship-borne.

In the Straits Settlements a small epidemic was noted at Singapore, and some cases also were reported in Province Wellesley. At Bangkok, the capital of Siam, cholera was prevalent from May to August, carrying off more than 700 victims. In French Indo-China cholera appeared in Annam, Cambodge, and in Cochin-China; while in Tongking a somewhat severe outbreak caused not far short of 6000 cases to come under official observation. In the Dutch East Indies cholera was epidemic at Batavia in the island of Java, where about 1200 cases were notified; and also at Samarang, where some 3350 persons were attacked between February and August and more than 2800 died; in Sourabaya, also in Java, and its immediate neighbourhood some 1260 cases were notified between February and October. At Palembang, in the island of Sumatra, cholera was prevalent during the year; and in West Borneo cases were reported at Pamangkiet. During most of 1910 cholera was present in the Philippine Islands, assuming a more virulent character during the summer months both in Manila and in the provinces.

In the Chinese Empire cholera is known to have appeared in the city of Swatow and its vicinity, causing over 3000 deaths; at Amoy, Fatshan, Hankow, and Pakhoi other outbreaks occurred, and some cases were also notified at Hong-Kong. In Japan the disease was prevalent on the island of Awaji, and also at Kobe, Osaka, Kyoto, Moji, Nagasaki, Yokohama, Fukuoka, as well as in other places. There was also an outbreak at Keelung, Taihoku, in the island of Formosa. In Manchuria the occurrence of cholera was certified at Newchwang, Dalny, Inkou, and Mukden. It is reported that some cases of cholera were landed from a steamer at the port of Chinampo in Korea.

Plague in India.

It is disappointing to find that in 1910 there was an increase in the number of fatal cases of plague recorded in India, as compared with the two previous years. In round numbers the deaths from this disease in 1908 and 1909 were respectively 150,000 and 175,000; but for the 10½ months to mid-November in 1910 the number had risen to more than 400,000. The provinces which suffered most in the present year were those which had the same misfortune in the two previous years—viz., the Punjab with 150,000 deaths in 1910, and the United Provinces of Agra and Oudh with 120,000. The next provinces which suffered much in point of plague mortality were Bengal, 34,000 deaths; and the Presidency of Bombay, 27,000.

The Advisory Committee for Plague Investigation in India, of which Surgeon-General A. M. BRANFOOT, I.M.S., C.I.E., is chairman, published in November a further series of reports in a special number of the *Journal of Hygiene*. These reports, among other matters, dealt with "the experimental production of plague epidemics among animals." A short interim report is also given by the Advisory Committee, embodying the chief conclusions which it has provisionally reached as a result of the investigations conducted in India from 1904 to 1909, relating specially to the mode of spread of plague.

Plague in the Far East.

In the Straits Settlements in April and May a few plague cases were notified in Singapore. At Bangkok, the capital of Siam, some cases also continued to come under observation during the year, though in no great numbers; altogether about 120 deaths were recorded from this cause. There was also an outbreak at Phrapatom, some 30 miles from Bangkok. In French Indo-China plague was epidemic at Pnom-Penh and other places in Cambodge; at Saigon and Cholen in Cochin-China, and at Choquan in Tonkin. A somewhat severe outbreak occurred in Quang-Tchiou-Wan, where in the first half of 1910 some 1400 cases came under official notice.

In China plague was heard of during the year at Amoy, Canton, Hong-Kong, Hankow, Swatow, Kulangsu, Hoihow, Liutschu, Ching-Chew, and in the districts of Chang-poo and Chao Yang, in the latter of which more than 3000 fatal cases were recorded in the first four months of the year. In Pakhoi a severe epidemic occurred in the summer and caused a third of the population to flee in panic from the city. At Shanghai in December some cases were notified, and when attempts were made to enforce preventive measures riots resulted. A number of plague cases occurred in Manchuria during the autumn, the infection being attributed to the hunting and handling of a species of marmot (tarabagan) which abounds in that region and which is said to suffer from plague.

In Japan localised outbreaks were observed at Kobe and Osaka, and also in the island of Shikuko. An imported case on board a ship from Hong-Kong was discovered at Yokohama. In the island of Formosa during the first half of the year only 19 cases were notified, a very considerable diminution of the amount reported in previous years.

Plague in Oceania.

For the first time during the last ten years no human cases of plague were reported in New South Wales, though a few infected rats were discovered in Sydney during April. It is interesting to mention that it is proposed to establish in the University of Sydney a prize in pathology in memory of the late Dr. T. C. PARKINSON, who died last year from plague in England while engaged in research work on that disease at the Elstree laboratory of the Lister Institute. No plague in man or rat was detected in Queensland or in Western Australia, but a single fatal case of suspected plague was reported on board a sailing vessel which arrived at Port Adelaide in South Australia in March.

In New Zealand a single case was notified at Auckland. An outbreak of plague was reported in the north of the island of New Caledonia during September among the natives. Only scattered cases occurred in the Hawaiian Islands, some cases being landed in June at Honolulu from a Japanese vessel from Kobe, on which rat infection is said to have been present. A few other cases occurred on shore in the following month, but there was no epidemic. Small groups of cases were also observed at Hilo and Honokaa, where an epizootic in rats was reported. Plague-infected rodents were found at Aiea and Puhuona, where, however, no human cases occurred.

Plague in America.

Plague was widely diffused throughout South America during 1910. Reports from Argentina are somewhat scanty, but it is beyond doubt that cases of plague occurred at Rosario in February and in Tucuman in the spring months. In Brazil localised outbreaks were reported from Rio de Janeiro, Bahia, Para, and Pernambuco. A number of towns and districts in Chili suffered from invasion of plague during the year, including Iquique, Taltal, Antofagasta, Santiago, Pisagua, and Mejillones. In Peru the disease was widespread, affecting many towns and departments, among which may be mentioned Arequipa, Mollendo, Cajamara, Callao, Lima, Lambayeque, Pacasmayo, Libertad, Pisco, and Piura. A somewhat severe epidemic, attaining its height in October, was experienced by Guayaquil, the capital of Ecuador, in which State also outbreaks were noted at

Babahoyo, Duran, Rocafuerte, and Milagro. Plague appeared at Caracas in Venezuela in July, and cases also occurred at Puerto Cabello. A few attacks of plague were notified in July at Port of Spain, the chief city and port of the island of Trinidad.

Only two cases of human plague were reported in the United States during 1910, both of them from the State of California, one occurring in June at San Benito, and the other in September at Santa Clara. There was, in addition, a widespread incidence of plague among ground squirrels in California, infected animals being found in the counties of Almeda, Contra Costa, Merced, Monterry, San Benito, San Joaquin, San Louis Obispo, Santa Clara, Santa Cruz, and Stanislaus. A single plague-infected rat was found at Seattle in the State of Washington, the last reported human case there dating back to 1907.

Plague in Africa.

The disease was again epidemic in Egypt during 1910, and in rather greater amount than in the previous year; up to the middle of November close upon 1100 cases had come under observation. Scattered cases occurred in Alexandria, Port Said, Damietta, and Ismailia. Thirteen Egyptian provinces were affected, and of these the chief sufferers were Assiout, Keneh, Menoufieh, and Fayoum. Some ships from India and the Far East landed occasional cases of plague at the Suez quarantine station before entering the canal, but the town of Suez remained free from plague during the year.

In German East Africa plague was notified in September at Lindi, where also rats and mice were found infected. At Zanzibar in the same month a few cases were reported, but no infection of rats was discovered, though many animals were carefully examined. Plague became epidemic in Mauritius in September and continued to prevail to the end of the year. Previous to this a few cases had appeared in each month, but only in small groups. To Port Louis, the capital of the island, a considerable number of the attacks were referred. Rats, mice, and musk rats were also affected, both in Port Louis and in the provinces. In Tunis during June several cases of plague were reported, and in September in Morocco a group of attacks was notified among the French troops at Busneco, which lies between Rabat and Casablanca.

Plague in Europe and the Near East.

An outbreak of plague began in Odessa in June and continued until November, about 140 cases being notified in that period, 42 of them terminating fatally. No mention is made in local reports of a coincident epizootic among rats, but notwithstanding this very stringent measures were enforced for rat destruction. In the government of Astrakhan from January to March plague was present in the Kirghiz Steppes in four settlements, and also in the Marmsk and Kalmuk camps. Another outbreak was reported in November in the same locality. The disease was also noted in Turkistan in July and August in the district of Prjevals. An outbreak occurred, too, in the Oural province in Djambeitine during August.

In England two cases were notified in the Port of London, both belonging to steamers lying in dock, and which had previously arrived from Bombay. One of these cases fell ill the day before his ship left London for Bombay and prior to the nature of the illness being diagnosed. Before this ship reached Marseilles three other cases occurred on board, two dying on the way; the third case, along with three more which developed on the following day, while the ship was being disinfected, were landed at the lazaret on the island of Frioul. From Marseilles to Port Said the ship was free, apparently, from infection; but before she reached Aden three fresh cases had come to light and were taken ashore to the port hospital. Finally, a further case was reported between Aden and Bombay. All the cases belonged to the native crew, mostly engaged in the kitchen of the ship, and although there were 330 passengers on board all remained free from plague. Three plague-infected rats were found in a London dock during the autumn. Some suspicious cases associated with rat-infection occurred in Suffolk, an account of which is given in another part of the Annus Medicus.

Early in November some plague cases were discovered in Lisbon in the Alfama quarter, the two first victims being lads employed in boiler cleaning on ships arriving from foreign ports. It is alleged that the infection was acquired while working on board a vessel which had recently come from East Africa. Altogether nine cases were notified and five of them proved fatal. There is no mention of infection among the local rats. A single case landed from a vessel coming from India was reported at Malta in July.

Sporadic cases occurred during the year in Beirût and Adalia, and also at a village 20 miles from Rhodes. Plague was again epidemic early in the year at Jeddah, the chief port of the Hedjaz, over 100 cases being certified. Among the fatal cases we regret to find the name of Dr. CESARE ZONCHELLO, the acting medical officer at Jeddah under the International Sanitary Council. Plague infection among rats was also present in Jeddah during the first months of the year. Further south of Jeddah along the coast plague was epidemic at Loheia and Hodeidah during April and May. On the island of Perim three cases were landed from a Bombay steamer in the month of May. At Basra, during April, June, and August, plague cases were reported and there was evidence of coincident infection of rats. In the early part of the year plague cases were met with in Bagdad, the expiring remains, apparently, of the epidemic of 1909. Bushire, on the eastern shores of the Persian Gulf, was the scene of a sharp plague outbreak during which 60 cases were notified.

Yellow Fever in South and Central America.

The north of Brazil remains a hotbed of yellow fever, although in the south and central parts of that Republic the disease, as a result of modern measures, has practically disappeared. But in the north Para, Pernambuco, and Manaos still foster the disease. It was at Manaos that the Amazon Yellow Fever Expedition, sent out by the Liverpool School of Tropical Medicine, established its headquarters under Dr. H. WOLFERSTAN THOMAS, upon whose interim report we commented in THE LANCET of July 30th of this year. More than 120 deaths from yellow fever were reported in 1910 at Manaos, while in Para nearly 300 fatal cases were certified in the first nine months of the year. Smaller outbreaks occurred in Pernambuco and Bahia.

In Nicaragua, at Managua, and in Venezuela at La Guaira, Puerto Cabello, Valencia, and Caracas yellow fever was reported. There was a sharp epidemic in Ecuador at Guayaquil, where about 260 cases and 100 deaths were recorded up to November; minor outbreaks in the same State were reported at Babahoyo and Duran. In Costa Rica the disease appeared in a number of places, including Limon, San Jose, Siquires, and Milagro. The occurrence of yellow fever in Santo Domingo, at Puerto Plata, Santiago, and La Vegu was certified in September; and it is noteworthy that most of those who fell victims to the disease were newcomers to the island. In April a few cases were notified to the authorities in Trinidad at Port of Spain.

Owing to the strict measures which are carried out in the Panama Canal zone, where formerly yellow fever was rife, and notwithstanding two separate shipborne importations of infected persons, no subsequent cases were observed. In Mexico during the autumn months several cases of yellow fever were reported at Campeche.

Dr. HARALD SEIDELIN, formerly Professor of Pathology

and Bacteriology at the Medical School, Merida, Yucatan, Mexico, continues to maintain his belief that he has discovered the micro-organism of yellow fever in certain protozoon-like bodies which he found in the blood of many of his patients stricken with the disease, but so far as we are aware his discovery has not been confirmed by any other observer.

Yellow Fever in West Africa.

In May, 1910, cases of yellow fever were notified at Koora, near Dakar, in the French colony of Senegal. In the same month some alarm in this country was caused by the announcement that the disease had appeared at Sekondi, and later at Axim in the Gold Coast Colony, also at Freetown, in Sierre Leone, some 19 fatal cases being reported. When it was known that yellow fever had broken out in West Africa Sir RUBERT BOYCE, F.R.S., at once offered his services to the Colonial Office, who accepted them, and with some six other medical men he left England in June to investigate and advise upon the outbreak. Fortunately, the epidemic did not assume very alarming proportions, and by the end of September cases had ceased to occur.

As a result of his own observations and of his study of the previous sickness and mortality statistics of a number of places in West Africa Sir RUBERT BOYCE came to the conclusion that yellow fever was endemic in that region, and that for a long series of years cases of the disease have been occurring, but which have been recorded under some other designation. He embodied his views in a paper which he read in November at the meeting of the Society of Tropical Medicine in London. There have, he thinks, been no fresh importations of infection from time to time, but that the reservoir of the disease has been present in the native population, who suffer mostly in childhood from a mild form of the disease. It is only when newcomers are attacked in a virulent form that the classical symptoms of yellow fever described in books are noted and the disease is diagnosed. The same views were advanced in reference to Martinique by the three military surgeons who investigated the matter there—viz., Dr. P. L. SIMOND, Dr. L. AUBERT, and Dr. F. NOC—whose report was published in the *Annales de l'Institut Pasteur*, and on which we commented in THE LANCET of March 26th.

Sir RUBERT BOYCE'S conclusions are, shortly, that yellow fever is endemic and common in West Africa, and that it has occurred in all its various forms, from the "embarras gastrique" to black vomit. He holds there is but one remedy, and that is destruction of the stegomyia which abounds in all the colonies in question.

Yellow Fever on Board Ships.

During the past year yellow fever has appeared on board a number of ships which have left infected ports. The following are a few examples which show that there is a possibility of the disease being conveyed from North Brazil to European ports.

1. The ss. *Rugia*, from Manaos and Para, arrived at Lisbon on April 3rd, and the master reported to the authorities that eight cases of yellow fever had occurred on board the vessel since leaving Manaos, four of them proving fatal. The four surviving patients were landed at the port lazaretto where they recovered. There was no subsequent extension of the infection. 2. The ss. *Augustine*, also from Manaos and Para, reached Liverpool in October, and the captain notified the port officers that six cases of yellow fever had been diagnosed on the voyage, and that two of them had died and been buried at sea; two had recovered before the ship reached England, and the remaining two were landed at the Liverpool port isolation hospital, where they recovered. 3. The ss. *Lanfranc*, which sailed, like the previous two ships, from Manaos and Para, arrived at Liverpool in August, and the master reported the death of one of the crew from suspected yellow fever on the voyage not long after leaving the coast of Brazil. The corpse had been buried at sea. 4. The ss. *Lanfranc* in a subsequent homeward voyage from Manaos and Para reached Liverpool in October, and reported that a member of the crew had died, with symptoms highly suggestive of yellow fever, on the voyage, and that his body had been committed to the deep; there were no subsequent cases.

Small-pox Abroad.

In Europe the chief country which suffered in 1910 from epidemic small-pox was Russia, more especially St. Petersburg, where more than 2000 cases occurred; Odessa, with over 550 cases; Riga, with close on 450 cases; and Warsaw, with more than 1100 cases. In Moscow 256 deaths from small-pox were certified up to November. Germany suffered from repeated importations of the infection and, notwithstanding her excellent vaccination arrangements, about 220 cases came under observation, many of the sufferers being foreigners, especially Russians and Italians. The information from Italy is not up to date, but during the first four months of the year nearly 1600 cases were notified. Spain also suffered from small-pox in 1910, epidemics occurring in several of her cities, including Barcelona and Madrid. In Portugal there was an outbreak at Lisbon, where not far short of 1000 cases were reported. The accounts from France are meagre, but it is known that in Paris over 200 attacks were certified. Smaller occurrences of small-pox were observed in Austria, Holland, Belgium, Greece, Malta, and Turkey.

Small-pox was present in Egypt most of the year, some 2700 cases being officially reported. Outbreaks, too, were notified in Algeria, Tripoli, Abyssinia, and at Zanzibar. The disease was epidemic in a number of localities in Persia, including Teheran. As usual, some Indian cities and provinces suffered from small-pox in 1910. In Bombay City somewhere about 1150 cases came under notice. The yearly epidemics in Bombay are associated with the return of the Indian pilgrims from the Hedjaz where the infection is contracted. Calcutta also suffered, but to a far smaller extent; there was also an outbreak at the port of Rangoon. In Ceylon, Siam, the Straits Settlements, French Indo China, the Dutch East Indies, the Philippines, China, Japan, and Korea small-pox manifested itself in varying amount during 1910.

In the Western Hemisphere the disease was epidemic in certain towns and districts in South America, more particularly in Brazil, Argentina, Uruguay, Chili, and Mexico. In the United States small-pox was epidemic, over 24,000 cases being notified, in a number of the States, including North Carolina, Kansas, Texas, Michigan, Oklahoma, and Utah, but the type was comparatively mild. In Canada small-pox appeared during the year in British Columbia, Manitoba, Ontario, and Nova Scotia.

Malta Fever.

A new commission has been appointed by the British Government to investigate the manner in which goats become infected by Malta fever. The evidence incriminating goat's milk as the means by which this disease is spread is accumulating. Epidemics have been reported in the past year in places where goats afford the main supply of milk. Outbreaks occurred in Algeria, Italy, Spain, in South Germany, and in parts of France; in the latter country the disease was observed in the departments of Var, Bouches du Rhône, Hérault, and Gard. The French Government has been urged to take measures for controlling the sale of Maltese goats, and the Academy of Medicine, at the instigation of Professor F. WIDAL, recently passed a resolution pressing local sanitary authorities to make the notification of Malta fever compulsory. It is said that at the present time 12 per cent. of the goats at Port Said, when tested by the agglutination

method, gave positive results with the M. melitensis. The BEY of Tunis, as a result of the researches of Dr. C. NICOLLE, has issued a decree forbidding the importation of Maltese goats.

Another of the continued fevers of Malta has now been investigated—namely, that known formerly as the "three days' fever," and now called phlebotomus fever. From researches made by Lieutenant-Colonel C. BIRT, R.A.M.C., it appears that the infection is transmitted to man by a species of sand fly, Phlebotomus papatasii, but the specific organism has not yet been discovered. It is believed to be ultra-microscopic, and therefore unrecognisable by our present methods.

Malaria.

Professor RONALD ROSS has published a "colossal" work on the Prevention of Malaria, with the help of a number of collaborators of repute. This work constitutes, perhaps, one of the most comprehensive treatises on the subject that have as yet been written. A new periodical devoted to malaria and called *Paludism* has been established in India, with Major S. P. JAMES as its editor. A commission has inquired into, and reported upon, the Mian Mir (Punjab) anti-malaria experiment, but we gather that there are some who do not yet regard this vexed question as being settled by the report.

Pellagra.

An influential committee was formed in London with a view to the investigation of the etiology of pellagra, and under their direction Dr. L. W. SAMBON proceeded to certain affected districts in Italy to study the disease in the spring and summer months of the year. This expert has since reported that the maize theory is untenable, and that in his opinion the disease is transmitted by a species of sandfly, the distribution of which coincides with the areas in which pellagra is endemic. The investigation is as yet incomplete, but hopes are expressed that funds will be forthcoming to enable Dr. SAMBON to be again despatched to Italy and other countries where the disease is prevalent so that his inquiries may be completed. In the United States of America a similar investigation is being undertaken, and already in Egypt an inquiry has been begun by the staff of the Egyptian Health Department at the instance of Dr. W. P. S. GRAHAM, the Director-General.

Leprosy.

Considerable advance has been made during the year in our knowledge of this disease, and success, we understand, has at last attended the efforts of certain scientists to cultivate the bacillus of leprosy outside the human body. Two experts—Dr. C. DUVAL in America and Dr. F. TWORT of the Brown Institute in this country—have, each independently of the other, discovered almost simultaneously a method of cultivating the B. lepræ on an artificial medium. This discovery may have far-reaching results in the direction of finding a curative treatment of a more reliable kind than any that have yet been put forward for leprosy.

Sleeping Sickness.

The advances in our knowledge of sleeping sickness were summed up in a paper read before the Society of Tropical Medicine in London recently by Dr. A. G. BAGSHAWE, the director of the Sleeping Sickness Bureau. There appear now to be grounds for believing that in Rhodesia the T. gambiense may be transmitted by some other species of tsetse fly than the G. palpalis, and a new human trypanosome has been discovered in the blood of a patient who contracted the disease in North-Eastern Rhodesia. The existence of a regular periodical increase of the parasites in a case of sleeping sickness has been discovered by Major R. ROSS and Dr. DAVID THOMSON.

FORENSIC MEDICINE.

The year 1910 has not been distinguished by any legislative enactment of marked importance to the medical profession; but the Housing and Town Planning Act, 1909, which received the Royal Assent early in December of that year, may be said to have come into force during the one now about to close. That Act had, as a feature of medical interest, the compulsory appointment of county medical officers of health by all county councils, under conditions already dealt with in these columns in the department of public health. The legal decisions of the past year, also, cannot be said to have affected the medical profession, or to have been of interest to its members in many or in conspicuous instances. The Workmen's Compensation Act has not provided any very considerable novelty in the way of extension of the meaning of the word "accident," such as those which have before attracted our attention. An interesting dispute, however, took place in a claim under this Act in one county court with regard to the medical examination of the workman at the request of the employer. It was contended that the medical man selected to make the examination, on account of methods adopted by him in past instances for the detection of malingering, and alleged to be unfair to the workman, must make his examination in the office, or at any rate in the presence of the claimant's solicitor. The impossibility of rendering such an examination effective under the conditions thus sought to be imposed was demonstrated by the medical practitioner against whom personally the protest was raised, and it was decided that the objection put forward was unfounded.

One of the most important criminal trials of recent years involving medical evidence was that of HARVEY HAWLEY CRIPPEN for the murder of his wife, known as BELLE ELMORE. The identifying of the human remains found under a floor of the house where the prisoner and the deceased had lived; the approximate fixing of the date of the crime; the connecting of the presence of the remains with the act of the prisoner by the discovery of certain clothing; and the establishing of the cause of death as being due to the use of a drug not commonly employed, but purchased by the prisoner in a large quantity, were all achieved solely by the skill and science of the experts employed by the Crown to elucidate a mystery which had attracted the public attention to an uncommon degree. The hanging of a very brutal and cold-blooded murderer, who during his life had practised extensively as a quack in medicine and dentistry, was due to incontrovertible medical testimony, which reinforced and supported the voluntary inquiries made by the deceased woman's friends and the efforts of the police in bringing an atrocious criminal to justice.

APPEALS AND ACTIONS IN THE HIGH COURTS.

The Liability of a Sanitary Authority and of Sellers of Unsound Meat (Hobbs v. The Winchester Corporation, 1910, 2 K.B. 471).—The Court of Appeal reversed a decision of Mr. Justice CHANNELL and established a principle of considerable importance to medical officers of health and sanitary authorities. A butcher at Winchester furnished meat to the barracks under conditions not here material, but which were alleged to have been infringed. To some of the meat supplied under the contract referred to the attention of the medical officer of health was drawn, who seized it and obtained a magistrate's order for its destruction, after which a prosecution was instituted against the butcher, which failed. The butcher then took proceedings under Section 308 of the Public Health Act, 1875, to have the damage which he had sustained through the dismissed prosecution assessed by an arbitrator. Section 308 provides for such compensation "where any person sustains any damage by reason of the

exercise of any of the powers of this Act in relation to any matter as to which he is not himself in default." The arbitrator found as facts that the butcher did not know when the meat was delivered that any part of it was unfit for food, that his servants did not know it, and that neither he nor they could have discovered its condition by any examination which he or they could reasonably have been expected to make, and that he was therefore not himself in default. He awarded as damages upon this part of the claim made before him £118, costs incurred in defending the case before the magistrates, and £300 for general damage to the claimant's business. A question as to how far the seizure of the meat or the prosecution constituted the "exercise of powers" contemplated by the section was argued before Mr. Justice CHANNELL, who in the end upheld the arbitrator's decision and confirmed his award of damages against the corporation, the prosecutors. The Court of Appeal reversed the decision of Mr. Justice CHANNELL on this point, holding that a butcher in the circumstances described sold unsound meat at his peril, and that therefore the sale of such meat was "a matter as to which he was himself in default" within section 308, whether he knew, or had reason to know, it was unsound or not. The *mens rea* was not necessary to constitute an offence.

The Variation of Charitable Bequests.—In the Court of Appeal an important decision was given in connexion with the carrying out the will of Mr. BENJAMIN WEIR. The deceased left two houses and a large sum of money upon trust for the establishment of a dispensary, cottage hospital, convalescent home, or other medical charity for the benefit of the inhabitants of Streatham and its neighbourhood. The trustees obtained an order from the Charity Commissioners sanctioning a scheme whereby a large portion of the money was to be applied to enlarging and maintaining the Bolingbroke Hospital, Battersea. The corporation of Wandsworth objected to this on the ground that it did not carry out the clearly expressed wish of the testator to benefit Streatham by a hospital within its boundaries to be named the Weir Hospital. In the Chancery Division Mr. Justice EVE refused to interfere with the order of the Charity Commissioners, but the Court of Appeal reversed this decision, holding that the trustees were bound by the terms of the will and had no right to say that the hospital proposed would be of no use, and that there was no evidence that it could not be established as directed by the testator upon such a scale that the whole of the money could properly be spent upon it. Their first duty was to carry out the wishes of the testator, provided that they were not contrary to public policy or impossible of fulfilment. If they had gone wrong in a matter of detail only the Court would not have interfered, but it was a question of principle, and it was the duty of the Court to intervene because the rules of law governing such matters had not been complied with.

Workmen's Compensation Act, 1906 (*Nisbet* v. *Rayne and Burn, 1910, 2 K.B. 689*): *Murder an Accident.*—It was held by the Court of Appeal in the case of a cashier of a colliery company, travelling, as it was his duty to do, periodically with a bag of money for the payment of the workmen employed by the company, that his murder, for the sake of robbery, was an accident within the meaning of the Act. It was an accident from the standpoint of the widow who claimed compensation, and it arose out of an employment which involved more than ordinary risk. The accident in such a case was an untoward and unforeseen event producing personal harm, and it was held not to be necessary in interpreting the word to exclude such occurrences as are not accidental in the popular sense, and to include those only in which there is a negation of wilfulness or intention.

The Form of a Medical Referee's Certificate under the Workmen's Compensation Act, 1906, after Appeal from a Certifying Surgeon.—On appeal in the case of Jones *v.* the Ebbw Vale Steel, Iron, and Coal Company, Limited, the Court of Appeal pointed out that on appeal against the certificate of a certifying surgeon of the disablement of a workman the medical referee must follow the prescribed form—that is to say, he must dismiss or allow the appeal, thus giving a decision only as to whether the certifying surgeon was right or wrong at the time when he dealt with the case. The medical referee in these circumstances is not concerned with the more recent aspects of the disability dealt with. The court recommended reconsideration of a regulation the objections to which are evident.

"*Dr.*" *Bodie.*—The Court of Appeal dismissed the appeal of the person known as "Dr." Bodie, made on the ground that the judge had misdirected the jury, that the verdict was against the weight of evidence, and that the damages were excessive. The Master of the Rolls observed "that he had never read a summing-up more clear, more directly addressed to the real points, and more free from objection on every possible ground that than of Mr. Justice DARLING. ..... The plaintiff's allegation was proved up to the hilt."

A Case under the Medicines Stamp Act (*Kirkby* v. *Taylor, 1910, 1 K.B. 529*).—The Medicines Stamp Act, 1812, contains an exemption with regard to the affixing of a stamp, involving the payment of a duty, upon medical preparations defined in the Act, in the case of such preparations when sold by a surgeon, apothecary, or druggist, "who hath served a regular apprenticeship." A druggist who had sold a bottle of "blood purifier" unstamped was summoned before magistrates, who held that he was not liable, because he had served the apprenticeship specified in the Act, the alleged apprenticeship having admittedly been served under an oral agreement only, and not under a written one. The Divisional Court held that the apprenticeship must be under a contract in writing, and remitted the case to the magistrates to convict.

Unqualified Practice of Dentistry: a Conviction Set Aside.—In the King's Bench Division, Dublin, the conviction was set aside of an unqualified person practising dentistry, who had been found by a magistrate to have taken and used the title or description "dentist," implying that he was specially qualified to practise dentistry and was registered. The charge also stated that he did take and use the title, addition, or description, "Mr. BYRNE, the expert adapter of teeth; extractions by my own special system, painless and bloodless." The court set aside the conviction on the ground that the defendant had so worded his advertisements that they did not go far enough to come within the Dentists Acts, or, in the words of one of the judges deciding the case, that he had only held out to the public that he was acting from the experience of his own skill, and not indicating any special qualification.

The Case of an Infant Mentally Defective.—In the Chancery Division Mr. Justice SWINFEN EADY was occupied for six days in hearing the claim of a young man, named DOUGLAS GORDON MACRAE, suing, through his committee, his stepmother, Mrs. HARNESS. This lady had been left a widow by the death of her husband, Mr. MACRAE, when her stepson, the plaintiff, was 15 years of age, and was showing symptoms of mental incapacity. She had an ample income from her husband's estate, and was allowed by trustees the sum of £3000 a year for the education and maintenance of the boy and his young sister. At first the former was placed in a house at Eastbourne, under the care of a medical man, Mr. H. N. HARNESS, expenditure being made upon him at the rate of £1200 a year. Afterwards Mrs. MACRAE married Mr. HARNESS, and the boy was placed in a home, where

six guineas a week were paid for his board, lodging, medical attendance, and for a private attendant to sleep in his room. A dispute took place as to extra fees for nurses during a period when these were required, and after this the lad was placed in the house of a medical man, an arrangement being made for an inclusive charge of 6 guineas per week and not more than £1 for amusements. A subsequent change brought the patient to the house of another medical man, where terms upon a like scale, with accommodation and treatment deemed to be unsuitable by the Master in Lunacy, led to the intervention of the Commissioners in Lunacy and to a claim against Mrs. HARNESS for an account of the sums paid to her for the maintenance and education of her stepson and her stepdaughter. D. G. MACRAE, now of age, is maintained under a scheme sanctioned by the Master in Lunacy at a cost of £1700 a year. Mr. Justice SWINFEN EADY granted a declaration that he had not been maintained in a reasonable and proper manner, having regard to his position and means, and that the defendant was liable to account for the money (£18,847) paid to her by the trustees of her late husband's will up to the time when the plaintiff came of age, proper deduction being made for money expended on the maintenance and education of him and his sister.

Action in respect of a Death ascribed to Ferro-silicon.—The widow of the owner of a canal boat was awarded damages in the High Court in respect of the death of her husband, a man named BAMFIELD, who had died, and whose death had been ascribed at the inquest held upon his body to ptomaine poisoning. Evidence was given at the trial that the cargo delivered to the deceased to carry on board his barge by the Goole and Sheffield Transport Company was described to him as scrap or general cargo, but that, in fact, it consisted of ferro-silicon in casks, and that the fumes escaping caused the death of the deceased. It was found that the cargo was dangerous, that BAMFIELD did not know its dangerous character, and that the plaintiff had proved her case and was entitled to £150 in respect of illness suffered by her and £175 for the loss of her husband.

THE COUNTY COURTS.

The Sale of Poisons under the Pharmacy Act, 1868–1908.—The Pharmaceutical Society sued WILLIAM NASH in the Kingston county court for a penalty under Section 15 of the Pharmacy Act, 1868, for selling poisons, he not being a registered pharmaceutical chemist or chemist and druggist. JAMES NASH, father of the defendant, held a licence under Section 2 of the Pharmacy Act, 1908, for the sale of poisonous compounds used in agriculture or horticulture, and WILLIAM NASH, who acted as assistant to his father in his shop, claimed to be entitled under this licence to sell for him the weed-killer which constituted the subject of the proceedings. His honour Judge HARINGTON reviewed the authorities in a considered judgment, and held that the sale of poisons under Section 2 of the Act of 1908 must be by the person holding the licence only, and gave judgment for the society for the amount claimed.

Damages against Hygienic Institutes.—Damages, amounting to £100 in each case, were recovered on the same day by two different plaintiffs, against the "London Hygienic Institute, Limited," and another "Hygienic Institute" having its address in Glasgow. In both instances large numbers of teeth had been extracted by unqualified operators at the "Institutes," with the result that the patients endured considerable suffering and injury to health. In the London case the plaintiff, a woman, had been confined to her bed for three weeks with a medical man in attendance. In the case at Glasgow the injuries inflicted included a broken jaw.

Damages against a Prescribing Druggist.—In an action brought in the Newport county court £10 damages were awarded against a druggist who treated the plaintiff for some time for an injured finger, with the result that it became septic, and the plaintiff in consequence lost his employment.

CASES UNDER THE WORKMEN'S COMPENSATION ACT, 1906.

The Medical Examination of a Workman on Behalf of the Employer.—An important point was raised in the Westminster county court, under the Workmen's Compensation Act, 1906. A workman had refused to submit himself to a medical examination when requested to do so by his employers, in a case in which the medical examiner appointed was Dr. R. J. COLLIE, and in which the workman's solicitors made it a condition of the examination that if it were made by the gentleman named it should take place in their office and in the presence of a member of their firm. It was alleged that Dr. COLLIE'S methods were unfair to the workman on the one hand, and on the other it was contended they were nothing of the kind, but were directed to ascertaining the truth, and that the examination could not be made properly so as to ascertain the truth with regard to the workman's capacity or incapacity for work in the presence of a third person, and in circumstances which might put him on his guard in his behaviour and in his answers to necessary questions. The county court judge held that there was no justification for seeking to impose the conditions mentioned, and that the workman had refused to comply with the Act and to submit himself to examination as required by it.

The Establishment of the Connexion between Alleged Accident and Death.—A seaman employed on board a steamship had to have an eye removed owing to conditions due to dust being blown into it. It was alleged that in consequence of the shock of the operation he fell into a despondent and debilitated condition and consequently died. The evidence of three medical witnesses was to the effect that death was due to exhaustion and shock in the patient following on primary cancer and cirrhosis of the liver, and attributed it to the operation, in that it brought about despondency followed by dyspepsia. Three other medical witnesses took the view that death was not due to the accident through the operation, but to the cancer which was pre-existent. The county court judge held that the chain was not complete and that it was not established on behalf of the claimant that the death of the workman had been caused by the accident.

THE OLD BAILEY.

Rex v. Crippen.—HAWLEY HARVEY CRIPPEN was tried and convicted, Oct. 18th to 22nd, at the Old Bailey for the murder of his wife, CORA CRIPPEN, the evidence identifying the remains of the deceased and connecting the murderer with his crime being mainly that of medical witnesses. Portions of the remains of a human being—headless, limbless, boneless, and without any parts calculated to prove the sex—were found under the floor of the cellar of a house whence the accused had escaped after inquiries had been set on foot with regard to the disappearance of his wife early in February of this year. The principal features of the medical evidence were as follows.

Mr. A. J. PEPPER and Dr. THOMAS MARSHALL visited 39, Hilldrop-crescent on July 14th and found animal remains in a hole in the cellar, with appearances of lime. Dr. W. H. WILLCOX on analysis found calcium hydrate and calcium carbonate in the earthy material round the remains corresponding to about 30 per cent. of quicklime. With the remains were a pair of female combinations and undervest, a man's handkerchief, and pyjama jacket, proved to be identical with a pyjama jacket admitted to be the prisoner's; also three Hinde's curlers containing hair. The hair was proved to be human, with roots at one end, and it showed signs of bleaching. Some loose hair showed signs of bleaching also, and it was proved that Mrs. CRIPPEN dyed

her hair. The remains included the heart, lungs, liver, kidneys, stomach, intestines, and portions of skin and muscles of a human adult, showing remarkable freedom from ordinary signs of bacterial putrefaction, especially as to the heart and kidneys. A relatively considerable amount of adipocere was present in the portions of skin and organs.

After examination and consideration of the conditions in which the remains were found Mr. PEPPER, Dr. MARSHALL, and Dr. WILLCOX were of the opinion that they had been buried from four to eight months, and that they were remains of an adult of young or middle age buried soon after death. A piece of skin, the establishing of the position of which was of extreme importance, was in the opinion of the medical witnesses of the Crown, with whom the medical witnesses for the defence, Dr. H. M. TURNBULL and Dr. R. C. B. WALL, ultimately agreed, from the lower part of the anterior abdominal wall. On this piece of skin, stretching from a line of hairs corresponding with pubic hairs, was a mark extending upwards four inches, smooth, showing some pigmentation and transverse striation, and with a slightly raised line along the middle of it. This mark was emphatically declared by Mr. PEPPER to be that of an old, stretched scar, and with this opinion, forming their own view independently, Dr. MARSHALL, Dr. B. H. SPILSBURY, and Dr. WILLCOX agreed. At the upper end of this mark it was joined by another curved mark, the two combining to form a mark roughly in the shape of a horseshoe. This curved mark the witnesses of the Crown attributed to a folding of the piece of skin, coming to their conclusion owing to the marks of sebaceous glands occurring in it and to characteristics of a scar observed in the first mark mentioned being absent. The witnesses for the defence attributed both marks—i.e., the whole of the "horseshoe"—to the folding of the skin and denied the presence of a scar. Considerable discussion took place as to the nature of this mark, the question whether there was or was not a scar being of vital importance in the identification of the remains, and a microscopical examination was held by the medical witnesses for the prosecution and defence. The evidence of a female friend of the deceased proved that she bore the scar of an operation in the position assigned to the mark identified as a scar by the medical witnesses for the Crown.

The manner in which the removal of the viscera of the chest and abdomen had been performed, as well as the other mutilation of the remains, indicated, in the opinion of the medical witnesses for the Crown, some anatomical knowledge, and it was proved that the accused claimed an American diploma from a homœopathic institution and had lived by the unqualified practice of medicine for many years in London. His doing this had a bearing also upon the question of the cause of death. The stomach, kidneys, intestines, and liver had been submitted to Dr. WILLCOX, who found in each of these organs an alkaloid which produced complete paralysis of the pupil of the eye of a cat lasting several days. He, Dr. WILLCOX, submitted all the organs to the Stas-Otto process, and from each obtained a mydriatic alkaloid. In each case a definite purple-violet colour was given by VITALI'S test, showing, in his opinion, that a vegetable mydriatic alkaloid was present—viz., atropine, hyoscyamine, or hyoscine. Having found a vegetable mydriatic alkaloid, he proceeded to determine which was present, and by special purification of the alkaloid obtained he found that it was not crystalline, but gummy, in character. Also he found that on treating a solution of the purified alkaloid with bromine in hydrobromic acid brown spheres were obtained. Hyoscyamine and atropine give crystals with this latter test and hyoscine spheres. From these characters Dr. WILLCOX concluded that the alkaloid present was hyoscine. Dr. A. P. LUFF confirmed independently the accuracy and suitability of the tests applied by Dr. WILLCOX, and supported his opinion that the mydriatic alkaloid found was a vegetable mydriatic alkaloid and was hyoscine. From the quantities found in the several organs submitted to him Dr. WILLCOX concluded that over half a grain of the salt must have been present in the whole body. The lungs, which were more putrefied than the other organs, showed only the merest trace of mydriatic alkaloid, and the distribution of it pointed to administration through the mouth, at the same time excluding the explanation that it was the result of putrefaction owing to the fact that the best-preserved organs yielded the greatest percentage of alkaloid.

CRIPPEN was proved by a druggist's assistant and by his own admission to have purchased 5 grains of hyoscine hydrobromide for the alleged purpose of compounding homœopathic medicines. He stated that he used two-thirds of the amount purchased for this purpose, but could not mention any patient for whom he had prescribed it, or say where the residue was. Evidence was given that it was a drug generally given hypodermically in doses of 1-100th to 1-200th grain, and never by the mouth in doses of half a grain; also, that it was not mentioned in the British or American homœopathic pharmacopœias, its uses being fully gone into on behalf of the prosecution and of the defence.

The conviction and execution of the prisoner are matters of recent occurrence and common knowledge.

AT THE ASSIZES.

Personation of a Medical Man.—At Durham assizes a sentence of six months' imprisonment in the second division was passed on ADAM MELROSE PORTEOUS, an unqualified person who, having at one time been a medical student, and having practised as a veterinary surgeon, for which he was qualified, had obtained the post of locum-tenent during the absence of the medical superintendent of the Durham County Asylum. This position he occupied without being detected at the time, and when he was arrested he had just returned from serving as a ship's surgeon. He used forged testimonials and passed himself off under the name and initials of Mr. W. J. PORTEOUS, a registered medical practitioner. He had at one time endeavoured to obtain the insertion of his own name in the medical directory, but had failed.

Improper Signing of a Death Certificate.—At Leeds assizes an unqualified person, employed by a medical practititioner as dispenser, bookkeeper, and surgery attendant, was charged with forging his employer's name on a certificate of the cause of death. It was admitted by the prisoner that he had done this frequently. In the case in question the medical employer had not seen the deceased, and he admitted that he did not know how many certificates might have been signed with his name by the accused person. He denied, however, having authorised him to sign any. A fine of 40*s.* was imposed.

IN THE CORONER'S COURTS.

An Unqualified Woman acting as a Midwife without Reward.—An unqualified woman received severe censure from the district coroner at Manchester owing to the death of a woman whom she had attended in childbirth from syncope consequent on hæmorrhage. No medical man had been sent for. The coroner told the midwife that she had had a narrow escape from being sent to trial for manslaughter. She was not subject to the Midwives Act as she was not proved to have made any charge for her services.

Case under the Midwives Act.—A medical man pointed out to the jury at an inquest held upon a woman who had died in childbirth, at which she had been attended by a

person acting as a midwife but not registered, the reason why he did not attend the case in response to a summons to do so. The guardians would have paid him a fee if the case had been one under the Midwives Act, but as the person attending was not a midwife qualified under the Act to practise he would have had to attend without any hope of payment. The case, therefore, was one for the intervention of the relieving officer and the medical officer of the union.

Technical Grounds for Refusing Payment.—In another instance recorded by a correspondent, and relevant to the last paragraph, a medical man sent in his claim to a board of guardians for attending two cases to which he had been summoned on the recommendation of a registered midwife. He received the following replies: As to (1), that he was out of date, although no limitation of date was named in a circular on the subject which he had received; as to (2), that the claim was not for attendance on a viable child. He was also informed that the guardians would see what they could do if he would satisfy them that he had taken reasonable steps to secure his fees from the persons attended.

IN THE POLICE COURTS.

Cases of Quackery: a Bogus Death Certificate.—A man named BANKS was fined £25 at the Clerkenwell police court with the alternative of three months' imprisonment, who was proved to be unqualified, to have attended a woman, stated to have suffered from bronchitis, until she died, and to have signed a certificate of the cause of death, thus necessitating subsequent rectification of the register by statutory declaration. The accused was believed by the husband of the deceased to be a medical man, and was known as Dr. BANKS, in which capacity he prescribed for a gentleman sent to call upon him by the Medical Defence Union who suffered from no disease, but who, he said, was affected by various complaints, including consumption.

An Unqualified Foreigner Falsely Pretending to be a Registered Medical Practitioner.—At the North London police-court it was proved that a man named WERNER had pretended that he was a medical practitioner, in which capacity he had prescribed for, and taken a fee of 5*s.* from, a representative of the Medical Defence Union, which was responsible for the prosecution. He had also attended a man who had taken poison and died, had attended at the inquest which followed, and had given evidence stating himself to be a registered medical practitioner. In advertisements in a newspaper he was described as a "French specialist."

Unregistered Woman Practising as a Midwife.—At Leeds three cases, heard in the police court on two consecutive days, called attention to the illegal practice as a midwife of a woman who, in defence to one summons, contended that she did not act as a midwife for payment, but only made a charge for nursing. She was not believed and was fined £5. In another case it was found that the same woman's daughter had been confined at her mother's house, but had registered the birth at a false address. For this she sought to excuse herself by alleging that she did it in order to avoid having her child vaccinated, the suggestion of the prosecution being that the real reason was to prevent attention being called to her mother's illegal practice as a midwife.

An Indecent Rogue.—A man, described as a clerk, was convicted of obtaining money from young women by falsely pretending that he was a medical man who was connected with two London hospitals and that he could obtain for his victims treatment in certain institutions, for admission to which preliminary fees were required. In order to convince the young women that they needed treatment he made pretended medical examinations, necessitating the removal of portions of their clothing, a procedure which, as the magistrate pointed out, might have been made the ground of a charge of indecent assault.

ANATOMY.

The Effect of Specialisation on Anatomy.

When we come to review the progress in anatomy from year to year we are more and more impressed by the fact that the modern specialisation in the practice of medicine is being attended by a rapid progress in our knowledge of the anatomy of the human body. The specialist studies the anatomy and physiology as well as the diseases of the part to which he has devoted himself, hence new facts regarding the structure of the eye and orbit, the ear, the nose, the pharynx and larynx we owe largely to the specialist. Radiologists are now the anatomists of the living; year by year they are vitalising the still-life studies of the dissecting-room. The rhinoscope, laryngoscope, bronchoscope, œsophagoscope, gastroscope, cystoscope, and proctoscope give the specialists an opportunity of examining in life parts which the anatomist can only see when they are changed by death. Old descriptions have to be altered to meet the new appearances. With specialisation in the practice of medicine there has been a compensatory generalisation in the study of fundamental subjects. The lines which divide the anatomist, physiologist, and pathologist are disappearing. We see anatomists crossing the border line and studying the function and pathology of the part at the same time as they work out its structure. Many of the best contributions to modern anatomy have been made by physiologists. Our present knowledge of the anatomy of the peripheral nervous system we owe to GASKELL, SHERRINGTON, HEAD, and LANGLEY. The best available description of the anatomy of the pituitary body is from the pen and microscope of a physiologist—Dr. P. T. HERRING. The modern movement which has revolutionised our conception of the anatomy of the heart was initiated five years ago by a pathologist—Professor ASCHOFF of Freiburg. Indeed, modern research on the anatomy of the heart is largely in the hands of pathologists, such as Professor MÖNCKEBERG, Dr. WALTER KOCH, and Dr. IVY MACKENZIE. A line cannot now be drawn between the experimental pharmacologist, experimental pathologist, and experimental physiologist—all are, at the same time, experimental anatomists.

Contributions by Zoologists.

The professional zoologist and comparative anatomist add their quota to our knowledge of the human body. In our pages during the year has appeared a notice of the discovery of a peculiar structure in the human brain by Professor A. DENDY and Mr. G. E. NICHOLS of King's College, London. They named it the "mesocœlic recess." It is situated on the roof of the aqueduct of Sylvius, just behind the posterior commissure. They have traced this structure from the lowest to the highest members of the vetebrate kingdom. Sir VICTOR HORSLEY had observed it in the brain of the monkey. Its nature is obscure, but it may prove to be of the nature of an orienting organ. The prolonged researches into the origin and nature of the trophoblast and fœtal membranes, by Mr. RICHARD ASSHETON, lecturer on zoology at Guy's Hospital, are opening up a sure access to a more complete understanding of these structures in man. It seems a "far cry" from the skeleton of man to the skeleton of sponges, yet no one who has read the studies made by Mr. W. N. F. WOODLAND, assistant professor of zoology at University College, London, on the formation of calcareous

spicules in sponges, can fail to see that he has thrown a flood of light on the behaviour of the osteoblast of the human body.

Here, too, is the place to note another anatomical event of the year—the discussion by anatomists and zoologists of the Gaskellian theory of the origin of vertebrates. Many medical men will refuse to believe that there is any connexion whatever between Dr. GASKELL'S zoological speculations and their future practice, but it is highly probable that there is. Dr. GASKELL has devoted 15 years to an inquiry into the origin of vertebrate animals, and he concludes that their ancestry must be sought for in the primitive crustacean stock, and not in Amphioxus and Tunicates. If this is so, then it is certain that an experimental study on such primitive forms of crustacea as now exist would solve many of the obscure problems of human physiology, especially those which relate to the organs of internal secretion. Dr. GASKELL has succeeded in throwing light on so many parts of the human and vertebrate body that were formerly obscure that there must be a large element of truth in his speculations, yet as regards other parts of the vertebrate body his hypothesis appears to break down. A zoological jury, empanelled by the Linnean Society during the present year, returned a verdict of "not proven," a verdict with which Dr. GASKELL and his followers do not agree.

Nervous System.

Coming now to deal with the more strictly anatomical contributions of the year, the first place must be given to Professor G. ELLIOT SMITH'S Arris and Gale lectures on "Some Problems Relating to the Evolution of the Brain," which were published in our pages in January last. It must be owned that, in spite of a clear easy style and an ample supply of simple, accurate, and original illustrations, these lectures are not easily read. They are packed with new fact and close reasoning, but those who master them will have their reward. For the first time we are presented with an evolutionary history of the various parts of the brain, a history on which comparative anatomists and physiologists must base their future work. Side by side with these lectures of Professor ELLIOT SMITH at the Royal College of Surgeons of England must be placed the Goulstonian lectures at the Royal College of Physicians of London by Dr. J. S. BOLTON. Dr. BOLTON'S lectures contain the results of many years of investigation of the structure of the cerebral cortex in health and in disease. He has given us the material on which a pathology of mental conditions may be firmly based, and on which we may be able to correlate mental ability and nerve structure.

Lectures by Dr. F. W. MOTT have served to direct attention to much that is obscure in our knowledge of the structures and spaces concerned with the cerebro-spinal fluid —a system which increases in importance with the wider application of spinal analgesia and the diagnosis and treatment of meningeal conditions. Dr. J. S. BARR has shown that the human cerebro-spinal fluid system can be irrigated or washed out in life by introducing the irrigating fluid into the lateral ventricle and draining it away at a lumbar puncture. Dr. JOHN CAMERON continues his researches on the multicellular formation of nerves; with Dr. W. MILLIGAN he has published an account of the development of the auditory nerve, the nerve fibrillæ of which they regard as a deposit by neuroblasts which occur along the track of the developing auditory fibres. Dr. WILFRED HARRIS has worked out the sensory distribution of the divisions of the fifth cranial nerve as seen after injections of alcohol for the relief of neuralgia. No better example of the manner in which the clinician can assist the anatomist and physiologist could be cited than Mr. SYDNEY SCOTT'S Arris and Gale lecture on the internal ear. He was able to show how each of the semicircular canals could be functionally stimulated, and to explain the various forms of nystagmus which may occur in cases of disease of the labyrinth.

Anatomy of the Head and Neck.

Mr. F. G. PARSONS has drawn attention to the highly artificial nature of the dissected layers described under the name of the cervical fascia; the fascia is really the packing of connective tissue in which the structures of the neck are set, the only real demarcated interfascial space being the post-pharyngeal. Professor PETER THOMPSON dealt with the development of the thyroid body in his Arris and Gale lectures, and pointed out that the median outgrowth formed, not only the isthmus, but a considerable part of the lateral lobes. Mr. F. D. THOMPSON has investigated the origin and structure of the parathyroid bodies. He agrees with Dr. DAVID FORSYTH that these bodies may come to contain colloid vesicles and resemble the thyroid in structure, but regards them as different in origin and in nature. Mr. J. E. FRAZER of King's College, London, has made important communications on the development of the human larynx, pharynx, and mouth. The lung bud he found to arise between the fifth (last pair) visceral (branchial) arches; the Eustachian tube and middle ear he found were composite in their origin, not, as usually supposed, merely a widening of the upper part of the first visceral cleft. The lower end of the pituitary outgrowth he observed to become drawn into the posterior border of the nasal septum during development, an observation which explains the occurrence of pituitary remnants there.

Professor E. FAWCETT of the University of Bristol continues to revolutionise our conception of the development of the bones of the human face and skull; nor must we forget to mention the inquiries of Professor FITZGERALD into the dimensions and correlations of the pituitary fossa in the base of the skull. It is remarkable how little we know of the anatomy and nature of the tonsil of the naso-pharynx, seeing how often—perhaps more frequently than any other part of the human body—it is the subject of operation. Professor J. SYMINGTON of Belfast has made a most welcome contribution to our knowledge of its anatomy; he describes its situation as extending in the roof of the naso-pharynx from the septum of the nose to the mid-point of the basilar process of the occipital bone. Mr. ARTHUR H. CHEATLE has drawn attention to the "fœtal" cells which occur constantly in the outer wall of the mastoidal antrum, and to the fact that this wall at birth may be composed of dense or of diploëtic bone. In 20 per cent. of adults the diploëtic form persists, and the dense form in little over 1 per cent.

The Thorax, Heart, and Lungs.

One of the most striking observations of the year is that by Dr. F. WOOD-JONES, assistant lecturer on anatomy at St. Thomas's Hospital, regarding the nature of the subclavian groove on the first rib. From time immemorial it has been taught that this groove is caused by the subclavian artery; Dr. WOOD-JONES has shown conclusively that it is caused by the pressure of the lowest cord of the brachial plexus. The observation has a direct clinical bearing. He noted, when the second dorsal nerve made a large contribution to the lowest cord of the plexus, that the groove was not only well marked, but that the rib itself was bent downwards at the point at which the lowest cord crossed it—evidence of pressure by the cord on the rib. When a cervical rib is present it either stops short at the cord or carries the cord, and is marked by a groove. It is well known that the pressure between the lowest cord and a cervical rib may lead to a partial paralysis of the arm; it is possible this may also occur in cases where no cervical rib is present, but where the brachial plexus is low in its origin. The same observer has drawn attention to the relationship of the thoracic duct to

the apices of the lungs and to the bodies of the vertebræ, and the possibility of tuberculous infection from the intestines reaching the lungs and vertebræ by the duct.

Further observations have been made on the diaphragm; the "massive collapse" of the basal part of the lung, cases of which have been recorded by Dr. W. PASTEUR, show how directly the diaphragm acts on the basal lobes, for in all of these cases the diaphragm was paralysed or limited in its movements. Radiology of the thorax presents the anatomy of the chest in a new aspect. Mr. A. C. JORDAN has described and illustrated the appearance and position of the arch of the aorta in normal and pathological conditions. Observations by Mr. R. J. GODLEE, Dr. STCLAIR THOMSON, Mr. FAULDER, and Professor C. VON EICKEN have thrown a new light on the position, movements, and behaviour of the trachea, bronchi, and œsophagus in the living.

As regards the anatomy of the heart, we see our knowledge extending in several directions. One of these concerns the distribution of what may be named the specialised musculature of the heart—musculature which is more directly concerned with the initiation and conduction of the heart-beat than with the act of contraction. The discovery by Dr. A. KEITH and Dr. MARTIN FLACK some years ago of a specialised node of muscular tissue (sino-auricular node) at the junction of the superior vena cava and the right auricle, has been the starting point for much further research. By means of the electro-cardiograph Dr. THOMAS LEWIS has traced the initial sign of the heart-beat to the region of the sino-auricular node. A paper by Dr. KEITH and Dr. IVY MACKENZIE has summarised in our pages the more recent researches on the anatomy of the specialised musculature of the heart. One of the most puzzling facts is the absence of the auriculo-ventricular bundle in the bird's heart; Dr. IVY MACKENZIE found that the bird's heart is also characterised by being supplied with peculiar neuro-muscular end-organs.

Another line of research concerns the nature and anatomy of the infundibulum of the right ventricle. Evidence has been accumulating for some time that this part of the mammalian heart represents a separate chamber of the lower vertebrate heart — the bulbus cordis. Professor PETER THOMPSON in his Arris and Gale lectures demonstrated that in the development of the human heart the infundibulum is at first a separate chamber comparable to the bulbus cordis, and that it becomes incorporated in the right ventricle as the infundibulum of that chamber. Further research will likely show that the function of the infundibulum is also different from that of the rest of the right ventricle.

A third line of research which is adding to our knowledge of the anatomy of the heart concerns its shape, its size, and its movements in various positions and physiological conditions of the body as observed during transillumination of the thorax. It is clear that the arbitrary topographical markings given by text-books as guides to the clinician need a complete revision in this matter.

The Alimentary Canal.

The researches which have been carried out by Dr. A. F. HERTZ, Dr. A. E. BARCLAY, Mr. A. C. JORDAN, and others, by studying the form, position, and movements of the alimentary canal in the living after administration of a bismuth-laden meal, materially improve our knowledge of applied anatomy. The form, the size, and the position of hollow viscera cannot be made to conform to any conventional description; they have a separate form for every phase of functional activity. We see that at certain points the canal is kept functionally closed. The circular musculature at the beginning and end of the œsophagus forms a functional sphincter. Professor KILLIAN described the upper œsophageal sphincter two years ago, and recognised that it was the cause of the pharyngeal diverticula which may occur just above it; Dr. A. KEITH, unaware of Professor KILLIAN'S discovery, has described the upper œsophageal sphincter and also given its relationship to pharyngeal diverticula. Dr. HERTZ denies the presence of a mid-gastric sphincter in the human stomach, and in this he is supported by Dr. BARCLAY. The position assigned to the mid-gastric sphincter corresponds to the point at which the pyloric movements commence. The pyloric sphincter is continuously in action.

Several further instances of hypertrophy of the pyloric sphincter in young children have been published by Mr. F. BARKER and Dr. L. MACKEY in our pages. The latter has pointed out how difficult it is to estimate the degree of hypertrophy by any system of measurements, and that cases of hypertrophy of this sphincter occur in children without giving rise to symptoms. In connexion with this matter attention may be directed to a new line of investigation opened up by Professor D. WATERSTON of King's College, London. As is well known, the tissues of the body survive for some time after the death of the individual. JOHN HUNTER showed that the arteries of the umbilical cord lived for three and a half days after separation from the child. Professor WATERSTON has observed that formalin has a selective action on the musculature of the alimentary canal, provided that the injection of a solution is made before death of the muscular tissue has occurred. The sphincteric muscular fibres are specially affected, so are the fibres of the pyloric part of the stomach, especially at the site where peristaltic waves are observed to commence in life. In a manner the action of formalin on non-striated musculature recalls the action of adrenalin.

Dr. P. T. CRYMBLE of Queen's University, Belfast, has published a most useful communication on the band of muscle which suspends the termination of the duodenum (the muscle of Treitz) and the relation of this band to the duodeno-jejunal fossæ. The series of cases published in our pages by Dr. N. I. SPRIGGS illustrate well the various forms of congenital occlusion of the intestine, especially those which occur at the entrance of the common bile-duct and near the terminal part of the ileum, the usual site of a Meckel's diverticulum. Dr. A. KEITH dealt with congenital occlusions and diverticula of the alimentary canal in demonstrations at the Museum of the Royal College of Surgeons of England. Several cases of acquired diverticula of the intestine have been described by Mr. GORDON TAYLOR and Dr. C. E. LAKIN and Mr. R. P. ROWLANDS, and the relationship between such diverticula and inflammatory conditions have been elucidated.

The Pelvis and Uro-Genital Organs.

As regards progress of our knowledge of this part of the body the work of Dr. R. H. PARAMORE stands pre-eminent. Here, again, we see the advantage of clinical aims being carried out by combining with them the methods of the anatomist and physiologist. In his Hunterian lectures he traced the evolution of the muscular floor of the pelvis throughout the whole kingdom of vertebrate animals, and showed that from its inception in fishes to its highest evolution in man the musculature of the pelvic floor is part of the musculature of the body wall, and directly concerned with the support of viscera and the regulation of intra-abdominal pressure. In further publications he has applied his observations and deductions to the human body and gynæcological practice, his main thesis being that in mechanical displacements of the pelvic viscera of the female the first endeavour of the clinician must be to try to restore the muscular pelvic diaphragm to a normal condition. Like every reformer, Dr. PARAMORE may find that the merit of his work gains but a tardy recognition; like all good work which is widely based on accurate observation, its acceptance cannot be long

delayed. A note by Dr. LÉON MACAULIFFE which appeared in our columns bears directly on the relationship between the viscera of the abdomen and pelvis and the musculature of the abdominal wall and perineal floor. Dr. MACAULIFFE calls attention to the observations of SIGAUD of Lyons, showing that the tonicity of the abdominal muscles is regulated by the condition of the abdominal viscera. Clinical observations are made daily which show the close relationship which exists between the viscera and the muscular parietes which support them through a reflex nerve mechanism.

Other observations of anatomical interest are those of Dr. B. P. WATSON (two cases of bicornuate uterus), of Dr. A. H. N. LEWERS (a cyst of Gartner's duct), and of Dr. V. BONNEY and Dr. B. GLENDINNING (adenomatosis of the vagina). Dr. F. WOOD-JONES has published further embryological evidence in support of Dr. BERRY HART'S explanation of the formation of the prepuce. Dr. BERRY HART regards the prepuce not as a fold of skin which has grown over the glans and thus covered it, but as the primitive outer sheath of the glans which has been separated by an ingrowth of epithelium, commencing its invasion in the region of the meatus. Dr. W. WRIGHT and Mr. T. H. C. BENIANS have reinvestigated the anatomy of the trigone of the bladder, and explained its relationship to the ureters and to the internal sphincter of the bladder.

Professor J. KAY JAMIESON and Mr. J. F. DOBSON of the University of Leeds have continued their researches on the distribution of lymphatics, their latest paper being a description of the lymphatics of the testicles. These end in from four to eight collecting vessels, which enter the chain of lymphatic glands placed in the retroperitoneal lumbar region. Attention may also be drawn to two cases of torsion of the testicle reported by Mr. A. G. BATE, for there can be no doubt that the possibility of torsion depends on an imperfect atrophy of the primitive mesentery of the testicle.

Reasons of space preclude a full reference to observations on the applied anatomy of the limbs. As in other parts of the body, the application of X rays is steadily altering our conception of the relationship and action of parts. Mention must be made of Mr. K. H. DIGBY'S paper on the attachments, movements, and function of the semilunar cartilages of the knee, and of Professor DIXON'S study of the internal structure of the upper extremity of the femur.

It is wonderful that a comparatively limited structure like the human body should have afforded so many generations of anatomists full scope for their inquiries, and yet more wonderful that in spite of an increasing annual output of observations the finality of anatomical knowledge, so often announced by famous anatomists of past times, seems as far off as ever.

THE NAVAL, MILITARY, AND INDIAN MEDICAL SERVICES.

THE ROYAL NAVY MEDICAL SERVICE.

Admiral Durnford's Committee of Inquiry.

The report of the committee, presided over by Sir JOHN DURNFORD, that was appointed to consider various questions connected with the medical service of the Royal Navy, has been presented to the Admiralty, but is still under consideration; what its recommendations may be, and whether they have been accepted or not, are matters as to which no information has been given to the public. This committee was appointed in March, 1909—that is, nearly two years ago. It held some 60 sittings, its discussions extended over nine months, and it submitted a unanimous report. So long a delay in promulgating regulations that will deal with the questions at issue is much to be regretted.

New Regulations for Admission.

New regulations for admission into the Royal Navy Medical Service were promulgated early in the year, and detailed at length in our issue of May 14th (p. 1358). These approximate in some ways to the rules in force for entrance into the Royal Army Medical Corps; nominations (except from colonial universities) are no longer allowed; successful candidates are not at once given commissions as surgeons, but are appointed acting surgeons during the time of their course of instruction; on passing the examination at the end of the course they receive commissions as surgeons; these, however, will date back from the date of the entrance examination. Once in every eight years every medical officer is required to undergo a post graduate course of instruction at a metropolitan hospital, during which time he will receive full pay, and will reside at the Royal Naval College, Greenwich. These altered conditions are to be welcomed, as tending to professional efficiency; but the regulation as to living at the Greenwich College will not be popular with married officers.

Powers of Command.

An important change in the interior economy of the service was hinted at in an Admiralty circular issued in April. This stated that it was contemplated "that the command of all officers of branches, other than the military branch, over their subordinates in their own departments shall be as definite as that of officers of the military branch." This direct disciplinary control of the sick-berth staff is one of the matters that have been most urgently insisted on by the heads of the Medical Service as necessary for the proper working of their hospital establishments.

Medical Consultative Board.

The Medical Consultative Board that has been established, analogous to the Advisory Board of the Army Medical Service, is presided over by the Medical Director-General, and has three civilian members, Sir W. WATSON CHEYNE, Sir DYCE DUCKWORTH, and Professor W. J. R. SIMPSON, together with Inspector-General H. TODD as naval member. There is also an Examining Board, including civilian teachers of eminence, analogous to the Board of the Army Medical Service.

Personal.

The Director-General, Inspector-General JAMES PORTER, has been promoted to a Knight Commandership of the Bath, to the general satisfaction of the service. Two veteran officers have joined the majority: Inspector-General THOMAS BOLSTER and Inspector-General ROBERT GRANT, C.B. The former had seen no war service; the latter was ashore in the Kaffir War of 1877, also in the Zulu War (1879) and in the Eastern Sudan operations in 1884.

THE ARMY MEDICAL SERVICE.

We have again to chronicle an uneventful year in the military forces as far as active service is concerned. The officers of the Royal Army Medical Corps have been steadily carrying on researches in various fields of work which will prove to be of permanent value.

Scientific Work of the Army Medical Service.

The Sleeping Sickness Commission, presided over by Colonel Sir DAVID BRUCE, returned from Uganda in April. The Commission had during the earlier researches come to the conclusion that the carrier fly, Glossina palpalis, lost its infective power 48 hours after having fed on the blood of an infected person. At the end of 1908 KLEINE, in German East Africa, showed that G. palpalis could convey Trypanosoma brucei even 50 days after it had fed on an infected animal. A large number of experiments have been conducted by the Commission, and it has been found that infectivity with T. gambiense remains up to 75 days, the trypanosomes undergoing development within the body of glossina. After prolonged investigation it appeared that the proportion of infected flies that retain infectivity for

so long a period is very small, about 2·5 per cent. For every case of infection propagated in this manner probably a thousand are caused by direct transference. Moreover, on the uninhabited shores of the Victoria Nyanza, after all the native population had been removed, experiments showed that G. palpalis could retain its infectivity for at least two years. Until lately it had been supposed that human beings were the only "reservoir" for the virus of T. gambiense, but the Commission's latest researches have shown that cattle also harbour the virus, and that so the infectivity of the tsetse-fly may be kept up for a very long period; although there is no proof so far that in nature this actually takes place. The same Commission has found that Malta fever exists in endemic form in Uganda, along the eastern shores of Lake Albert Edward, under the name of *muhinyo*. M. melitensis was detected in the spleen of patients suffering from the disease, also in the spleen of goats, whose milk had been drunk by the sufferers.

It has been decided to appoint another Malta Fever Commission to investigate the mode in which goats become infected with M. melitensis; this is now apparently the only matter that requires to be settled. During 1909 one case of Malta fever occurred amongst the military, and nine amongst the naval, population. The civil inhabitants still suffer to a considerable extent, and it is not practicable to prohibit their use of goat's milk.

Lieutenant-Colonel C. BIRT has studied the epidemiology of the "simple continued fever," or "three-day fever" of Malta and Crete, and has proved by actual experiment that it is a specific affection conveyed by Phlebotomus papatasii (a sandfly), similar to, but milder than, the Pappataciefieber described by DOERR in Herzegovina (1909). Lieutenant-Colonel C. H. MELVILLE has made a valuable contribution to applied physiology in a study of the food requirements for sustenance and for active work, based on actual observations conducted with great care.

Military Medical Organisation.

The advances in organisation that were chronicled in our review of last year's work have been continued during 1910. In the extensive field manœuvres that have been carried out on Salisbury Plain and elsewhere the medical service has taken its full share, and with a nearer approach to reality than ever before. We are sure that whatever expense is incurred in these operations, to take part in which a considerable number of officers and men are removed from their ordinary and routine duties, the result is well worth it. The actual practice in working the field ambulances has been of the greatest value, not only to the medical, but also to the regimental and transport *personnel* concerned.

The scheme for organising voluntary aid for the sick and wounded in the event of war occurring in this country has developed considerably. The British Red Cross Society is the central body, and under its auspices branches have been formed in many counties. Sir F. TREVES has given much help in explaining the aims and methods of the society throughout the kingdom. We doubt if, even now, the profession, or the public generally, are alive to the vital importance of this matter. The medical practitioner, both in town and country, is commonly a very hard-working man, with little leisure, or perhaps inclination, for taking up quasi-military work seriously. Yet busy men in other callings do so, and we believe that if the real objects and vital necessity of this organisation were properly put before them (as Sir F. TREVES has been doing in many places) there would be a large addition to the medical *personnel*. It appears that there has been some difficulty in filling up the strength of the voluntary aid detachments, and it is claimed that "much more liberal facilities" should be granted—that is, a much lower standard of efficiency accepted—for the nursing staff than has hitherto been the case in the ambulance department of the Order of St. John. Any such relaxation in the standard of training and examination must be very carefully considered if the organisation is to be of practical use in time of need.

Progress is being made in the development of the Sanitary Corps of the Territorial Force, in which many medical officers of health throughout the country are taking an active part. A well-attended conference of medical officers of the West Riding area was held at Leeds in March, presided over by the general commanding the division; views were exchanged and demonstrations given of sanitary appliances for field use.

Personnel.

Consequent on the retirement of Sir ALFRED KEOGH, Surgeon-General W. L. GUBBINS, C.B., M.V.O., was appointed Director-General of the Army Medical Service on March 6th. This officer has had a distinguished war record in the Afghan and South African campaigns, and had previously had considerable administrative experience, having been Assistant Director and Deputy Director-General at the War Office and Principal Medical Officer in India. Considerable comment was made at the time in service circles and in the press on the fact that the provisions of the still recent Royal Warrant regulating promotion were disregarded by the retention of a Surgeon-General on the active list beyond the age of 60. No one has attempted to dispute the ability and fitness for his position of the present Director-General, but the fact that the highest military authorities have broken their own regulations, or, rather, infringed the articles of a Royal Warrant (which carries, or ought to carry, much higher authority than any departmental code of regulations), is one that is, on grounds of principle, to be regretted. It is setting a bad example. Without doubt a considerable feeling of uneasiness was created amongst the senior officers of the Medical Service. We do not think this was unreasonable. Colonel W. BABTIE, V.C., C.M.G., became Deputy Director-General, with temporary rank of surgeon-general, and Colonel M. W. O'KEEFFE was appointed Inspector of Medical Services. At the Royal Army Medical College Major C. G. SPENCER, F.R.C.S., has vacated the post of professor of surgery and has been succeeded by Major E. M. PILCHER, F.R.C.S.

Obituary.

We have to record the deaths of Surgeon-Major T. E. HALE, V.C., C.B., who won his Cross in the Crimea and afterwards served through the Indian Mutiny; Surgeon-General G. L. HINDE, C.B.; Lieutenant-Colonel J. P. H. BOILEAU, at one time assistant professor of pathology at Netley, and a writer on professional and service subjects; Surgeon-General J. G. FAUGHT; Lieutenant-Colonel H. R. GREENE PASHA, the first Director of Egyptian Sanitary Administration after the British occupation in 1882; Dr. JOHN ANDERSON, C.I.E., formerly surgeon to the Viceroy of India, and for many years in consulting practice in Harley-street, a man of many friends and much beloved; Colonel F. H. WELCH, formerly assistant professor of pathology at Netley, a writer on pathological and clinical subjects, and a frequent contributor to our columns; Surgeon-General J. SINCLAIR, a principal medical officer in the Abyssinian expedition of 1867; and Lieutenant-Colonel C. M. DOUGLAS, V.C., retired A.M.S., who obtained his Cross in 1867 for rescuing comrades under circumstances of great danger at the Andaman Islands. He retired in 1882.

No reference to the loss sustained by death in the military ranks of the profession during the past year can be made without a tribute to the memory of FLORENCE NIGHTINGALE, the founder of modern nursing, and more especially of nursing for the sick and wounded in war.

THE INDIAN MEDICAL SERVICE.

It must be admitted that the feelings of unrest referred to in our annual review for last year have in no degree diminished amongst officers of the Indian Medical Service during the year just past. It may be remembered that the Secretary of State had decided that the increase in *personnel*, acknowledged on all sides to be necessary, should be met, not by an increase on the civil side of the existing service, but by gradually extending the employment of civil medical practitioners recruited in India. Surgeon-General LUKIS, who succeeded Sir GERALD BOMFORD as Director-General on Jan. 1st, made an important speech at Simla in July, in which he emphatically declared that the fears which had been expressed that the palmy days of the Indian Medical Service had passed away were entirely groundless, and stated his firm conviction that the service would flourish more vigorously than ever. He alluded to, and deprecated, the growing tendency to estrangement between the civil and military branches, and urged the officers in civil employ not to forget that they were military officers and that the main object for which they were put in charge of civil hospitals was that they might become more efficient surgeons, and therefore be of more use to their country in time of war. The DIRECTOR-GENERAL no doubt intended the term "surgeons" to include all branches of the profession; as in modern warfare, it is now generally acknowledged that the treatment of disease, and still more its prevention, are of enormously greater importance than any surgical procedures. It might be thought that the medical and surgical care of the 300 million native inhabitants of India would be a sufficient charge for a portion, at all events, of the Indian Medical Service without any ulterior regard for military practice (except in the event of national emergency), and undoubtedly this has been the view which has been generally held in past years. Our contemporary, the *Indian Medical Gazette*, alluding to the tendency which exists to depreciate the civil side of the service, recalls the splendid services the civil surgeons have rendered to surgery, instancing especially operations for calculus and cataract. It is difficult to imagine that these and the many other advances in all branches of medicine and surgery that we owe to our colleagues in India, would have taken place if their views had been limited by the needs of war service. The civil surgeons of India have indeed been the backbone of the Indian Medical Service; and by their energy and skill, and the influence they exerted on native princes and nobles, so that necessary funds should be forthcoming for hospitals, &c., have accomplished a magnificent work for humanity, far exceeding in its scope anything that could have arisen from the military side of the profession.

Scientific Work of the Indian Medical Service.

The chief scientific work of the past year has been the outcome of the Malaria Conference of 1909. A central scientific committee has been established at Simla, which will map out general lines of investigation, and also undertake research, both at the central institute and in the field. Secondly, each province has an organisation for the detailed investigation of malaria. Thirdly, all the provincial "malariologists" will meet the central committee at Simla every autumn. The establishment of this organisation marks a most important step in the public health service of India. Antimalarial operations have been carried out in many places. In Bombay, according to MCKENDRICK, Nyssorhynchus stephensi is the only important carrier-mosquito.

A further report on plague has been submitted by the advisory committee. The dependence of human plague on rat plague is again emphasised; its spread among rats is due to fleas; during a plague epidemic the disease in man is contracted from rats, also through the agency of fleas, in most cases. It was found that there is a definite seasonal variation in the prevalence of fleas closely associated with plague prevalence. The valuable Scientific Memoirs by Indian medical officers published by the Government of India have been noticed from time to time in these columns. During the past year these have included observations by Major G. LAMB and Captain A. G. MCKENDRICK on Atrophic Rabies in Animals; a research on Piroplasma Canis by Captain S. R. CHRISTOPHERS; an inquiry into Anti-rabic Immunisation by Captain W. F. HARVEY and Captain MCKENDRICK; and an elaborate investigation by Captain D. MCCAY on Bengal Dietaries. All of these are works of considerable importance and permanent value.

Study Leave.

New regulations have been issued allowing study leave to officers of the Indian Medical Service at the rate of one month for each year of service, up to 12 months in all; it may be taken at any time, but not more than twice in an officer's service. This is a most judicious concession.

Personal.

Sir GERALD BOMFORD retired from the post of Director-General on Jan. 1st, 1910, and was succeeded by Lieutenant-Colonel C. P. LUKIS, whose promotion to Surgeon-General was gazetted on March 22nd. Colonel W. G. KING, C.I.E., so well known for his distinguished services as Sanitary Commissioner in Madras, and especially in connexion with vaccination, retired in May. We regret to record the death of two valuable medical officers from cholera—Major J. C. WEIR, R.A.M.C., at Darjiling; and Captain E. D. SIMSON, at Nowshera. They were both very highly esteemed and universally regretted.

The Civil Medical Profession in India.

Questions have been asked in Parliament as to the intentions of the Government with regard to Lord MORLEY'S despatch of last year; no further pronouncement has been made. It is evident that the native members of the profession are expecting that changes will take place. A question was asked by the Hon. Mr. GOKHALE at the Viceroy's Council in March as to what steps were in contemplation to give effect to Lord MORLEY'S recommendations. The only answer given was to the effect that the Government is considering the possibility of throwing open certain of the teaching appointments at the medical colleges to "non-official medical men." It is asked also what steps can be taken to extend the employment of civil medical practitioners recruited in India. At a subsequent meeting of the Council assurances were given of the Government of India's "full and sympathetic consideration" of the proposals; as it was about to address the Secretary of State on the subject, it was unable to give any further information for the present.

It cannot be too clearly understood that there is already an ample field in India for the energies of native medical men, who are thoroughly educated and equipped for the practice of their profession, and who possess the mental and moral qualities necessary to attain success in a scientific professional career. But a high standard is necessary for the attainment of success, and up to the present the number who have reached this standard has not been large, either in the Indian Medical Service or in the so-called "independent medical profession." As time goes on there is no doubt that the number who reach this high standard will increase; no doubt the number of high and responsible appointments available will also increase. The Government of India evidently does not consider that any sudden change can be made, nor even any rapid advance, at the present time; in

this we believe it is well advised. We fear, however, that the promulgation of the proposed changes is exercising an unfavourable effect on the status and popularity of the Indian Medical Service. For some years past it has not attracted so many competitors for the appointments offered as was formerly the case; and there is certainly a feeling abroad that its attractions are materially lessened.

PHARMACY.

Scientific Progress.

The later developments of pharmacy have been determined by commercial rather than scientific influences, and owing to causes of a material character the majority of the members of the medical calling are not able to devote any considerable amount of time to pharmaceutical research. There still remain, however, a number of earnest workers in the scientific field upon whom depends the advancement of pharmacy proper.

During the past year much useful work has been accomplished in connexion with the revision of the British Pharmacopœia, and in the spring a second report was issued by the Committee of Reference in Pharmacy to the Pharmacopœia Committee of the General Medical Council. This dealt with the monographs for extractum glycyrrhizæ liquidum to liquor magnesii carbonatis, and gave a general description of a process of repercolation. The committee has been steadily at work throughout the year, and it is expected that the final report will be ready by May, 1911.

In this connexion two members of the committee, who have opportunities of producing and examining essential oils, recorded their views at an evening meeting of the Pharmaceutical Society, and made a number of suggestions which may be taken as the basis for the monographs of the next edition of the Pharmacopœia. While it is now possible to assay many of the essential oils for what are admittedly their most important constituents, the authors confessed that the time had not yet arrived to replace the natural oils by these constituents. Just as in the Pharmacopœia we now have nux vomica and strychnine, cinchona and quinine, opium and morphine, so we have peppermint oil and menthol, and it would be well to retain such oils as dill and caraway, and not to replace them by, or even to include, carvone.

Another evening meeting of the Pharmaceutical Society was devoted to the consideration of oils, fats, and waxes, when two members of the Committee of Reference suggested a basis for the official monographs on these substances. Much trouble has been caused in the past owing to the insufficiency of the official tests as a means of insuring that degree of purity necessary in articles required for medicinal use, and the authors expressed the opinion that the tests in the official monographs should, therefore, be as comprehensive as possible. They suggested the desirability of introducing figures for the saponification value, the iodine value, the percentage of free acid, the percentage of unsaponifiable matter, and the refractive index. Material has thus been furnished which should prove of great value in the production of the next Pharmacopœia.

In addition to the communications from members of the Committee of Reference, papers of practical utility have been contributed at meetings of the Pharmaceutical Society by independent workers. Among these was a paper by Professor H. G. GREENISH, in which a method was described for detecting powders manufactured from "worm-eaten" drugs, for which purpose no suitable tests have been available hitherto.

Early in the year the Pharmaceutical Society appointed a committee for the revision of the British Pharmaceutical Codex, and satisfactory progress is being made with the work.

Brief abstracts of some of the papers contributed at this year's meeting of the British Pharmaceutical Conference have already appeared in THE LANCET, and the papers and discussions on the question of the standardisation of disinfectants were printed at some length. Since its foundation 47 years ago the conference has contributed in no small measure to the advancement of pharmaceutical science, and the character of the communications presented at this year's meeting bears witness to the fact that the attention of pharmacists is not wholly absorbed by matters of a trading character. The President, Mr. F. RANSOM, put forward the suggestion that a joint committee, composed of medical practitioners and pharmacists, should be formed for the purpose of organising research work, and expressed the opinion that more valuable results might be obtained if several classes of investigators were to work together. An example of the usefulness of a pharmacologist and a pharmacist working in collaboration was furnished in a paper in which it was shown by Mr. J. H. FRANKLIN, a pharmacist, that in the manufacture of liquid extract of ergot it is better to use a percentage of alcohol in the menstruum rather than water only; and Dr. G. S. HAYNES demonstrated that the result of preparing an extract with a semi-alcoholic menstruum is to increase the physiological activity, as compared with watery extract.

At the Tenth International Congress of Pharmacy, held in Brussels towards the end of the summer, some important recommendations were made relating to the question of international standards, and it was decided to request the Belgian Government to convene an international congress for the unification of methods for estimating potent drugs, and to recommend that for the estimation of alkaloids preference should be given to gravimetric methods. It was also unanimously decided to recommend pharmacopœial authorities to adopt, as far as possible, normal reagents or some multiple of the normal.

Pharmaceutical Education.

One of the main provisions of the Poisons and Pharmacy Act, which came into force on April 1st last year, was that which gave the Pharmaceutical Society power to make by-laws requiring candidates for the qualifying examination to produce evidence of having undergone a prescribed course of study; during the year the members of the Board of Examiners in London and Edinburgh were invited to assist the society's council in devising an appropriate educational scheme, and the matter is now under consideration. At present it is no part of the duty of the council to inquire how or where candidates obtained their knowledge, but it is quite evident from the high percentage of rejected candidates (about 60 per cent.) at the examinations that a large proportion of them are inadequately trained. A suggestion which seems to meet with general approval is that the student should be required to pass his preliminary examination before his period of apprenticeship begins; that during the three years of pupilage he should attend classes in chemistry, physics, and botany; and that at the end of that period he should be eligible to enter for an intermediate examination. Having passed such an examination, he should attend a course of lectures and laboratory instruction at a recognised institution before entering for the final examination. It is probable that the adoption of some such scheme as the above would have the effect desired without unnecessarily increasing the student's expenditure.

Administration of the Pharmacy Acts.

During the year a large number of cases of alleged infringements of the Pharmacy Acts have been investigated and legal proceedings instituted against offenders. Many such cases have arisen as a result of the creation of a new class of poison sellers, for the Act of 1908 empowered local

authorities to grant licences to nurserymen, seedsmen, and others to sell horticultural and agricultural preparations containing arsenic and nicotine. Some of these licensees do not seem to appreciate the fact that it is extremely important in the public interest that the regulations under which poisons are sold should be minutely observed, and, in consequence of neglect to observe the proper precautions, a number of them have been proceeded against and fined. In several cases penalties have been recovered in county courts from assistants to licensed poison-sellers for selling poisons, and in one such case the defendant appealed against the decision of the judge at Kingston-on-Thames county court. The appeal was heard on Dec. 14th when it was contended on behalf of the appellant that the licence of an employer covered persons employed by him at the premises in respect of which he was granted the licence. Mr. Justice PHILLIMORE and Mr. Justice HORRIDGE, sitting as a Divisional Court, dismissed the appeal, holding that just as registered pharmacists cannot shield their unqualified assistants, so licensed persons cannot shield unqualified or unlicensed persons.

Striking evidence of the utility of the regulation requiring particulars of transactions in certain toxic substances to be entered in a poison book was furnished in the summer at the trial of CRIPPEN who poisoned his victim with hyoscine hydrobromide, a substance which is in Part I. of the Poison Schedule. It was stated in the annual report of the Registrar of the Pharmaceutical Society that in 15 cases of alleged infringement of the Pharmacy Acts which had been reported it was found upon analysis that the poison asked for had been omitted from the articles purchased and proceedings could not therefore be taken under the Pharmacy Acts. Such a practice is obviously fraught with considerable danger, and the Society has endeavoured, during the present year, to put a stop to it by instituting proceedings against several of the vendors under the Merchandise Marks Act.

In connexion with the interpretation of the Pharmacy Act of 1868 a matter which has long been in doubt was definitely settled by the decision of a Divisional Court in April. The question for the court was whether pharmacists trading under names other than their own were required to have their own names printed on the labels on packages in which poisons are sold. The magistrate at Old-street police court held that the "trade name" is not sufficient to comply with Section XVII., which requires that all poisons sold by retail shall be labelled with the name of the "seller," but a Divisional Court reversed the magistrate's decision, holding that it was in compliance with the provisions of that section if the name under which a registered person trades appears on the poison label.

The Dispensing of Medicines.

A committee consisting of ten medical men (selected by the British Medical Association) and ten pharmacists (selected by the British Pharmaceutical Conference) was appointed in the summer to consider whether it is possible to make recommendations with regard to the question of dispensing by medical practitioners, and the result of their deliberations is awaited with interest by chemists and druggists. A related topic, or rather a topic which it has become customary to associate with the question of dispensing by medical practitioners—namely, that of counter prescribing by pharmacists—was dealt with in a Blue-book published in December. The statements therein made have not been publicly discussed by pharmaceutical associations, but the council of the Pharmaceutical Society has appointed a subcommittee to consider them. No legislative effect has as yet been given to the resolution of the Executive Committee of the General Medical Council, informing the Lord President of the Council that the committee approved of the suggestion that the regulations as to the methods of storing and dispensing poisons applicable to pharmacists should be extended to medical men.

Organisation and Other Matters.

Something like a hundred local pharmaceutical associations are in existence, and the council of the Pharmaceutical Society has shown its appreciation of the value of organisation by appointing a special committee whose object it is to foster the movement and guide it into useful channels. Mr. W. S. GLYN-JONES, the candidate chosen by the Pharmacists Parliamentary Fund, has obtained a seat in the House of Commons as the representative of Stepney. Mr. GLYN-JONES was for many years in business as a chemist and druggist, but is now in practice as a barrister, and is Parliamentary secretary of the Pharmaceutical Society. The direct representation of pharmacy in Parliament should, in such capable hands, be of much benefit to the craft.

In the early summer pharmacy sustained a heavy loss by the death of Mr. MICHAEL CARTEIGHE, who was for 14 years President of the Pharmaceutical Society, and a useful member of the Council up to the time of his death. It was his constant endeavour to raise the standard of pharmaceutical education and to establish pharmacy on a professional basis. Although he was only partially successful, the fact that pharmacy to-day is in no worse position than it is, is mainly due to his efforts on behalf of a calling to which he devoted the greater part of his life.

CHEMISTRY.

A Triumph of Synthesis.

Chemistry this year may lay claim to a great synthetic triumph for medicine. It has produced "606," EHRLICH'S new specific for the treatment of syphilis. Arsenic in the correct position in the benzene nucleus appears to be the key to the situation. The position of the amido radicle is, however, of the utmost importance, for it was only after the discovery that in atoxyl the amido-group was not bound up with the arsenic that "606" was discovered. In "606" arsenic is trivalent, not pentavalent, which may have much to do with the efficacy of the remedy. Whether, as Dr. JAMES MCINTOSH and Mr. PAUL FILDES put it in a paper published in our columns of Dec. 10th, the amido radicle acts as the anchoring agent or as an auxiliary to the toxic influence of arsenic is not quite clear, but it seems that the transposition of the amido radicle into the third position of the benzene nucleus has brought about a marked diminution in the organotropic properties of the medicament without reducing in any way its parasitotropic qualities. The power of the chemist thus to alter the architecture of the molecule at will is like the moving of a single piece on the chess-board, which changes the position from one of apparent indifference to one of intense power. Chemists may well be proud of this synthetic achievement.

Radium, a Metal.

The production of radium in the metallic state may not possess any medical significance, but it is at all events important that the rare element has been recognised to belong to the metallic family of which barium, strontium, and calcium are members. Metallic radium was obtained by Madame CURIE and M. A. DEBIERNE, and the result was reported to the Academy of Sciences in Paris on Sept. 5th, just a little over a hundred years after Sir HUMPHRY DAVY succeeded in isolating the metals potassium and sodium.

Degradation and Transmutation.

Chemists do not appear to have got much farther with the theory of the degradation of the atom. The change of radium into, amongst other things, helium has been demonstrated, but it seems hard to get tangible proof that gold,

say, can be converted into copper. Madame CURIE, however, hopes to be able to show that one of the degradation products of polonium is lead. Of course, the demonstration of decay has only been made so far with the unstable element, but it is conceivable that with the immense factor of time in operation the noble metals gradually fall away from their high station. Thus the world's supply of a metal known now as copper might, for aught we know, have been gold ages and ages ago.

The Pathology of the Soil.

A remarkable light has been thrown upon the conditions which govern the fertility of the soil, and the continued investigations in this direction are yielding results of the utmost importance. The interesting observation has been made that the fertility of the soil can be increased very greatly by certain antiseptic treatment or by heating it to a definite temperature. It was found, for example, that when certain soils were heated to a temperature of 100° C. for two hours they yielded twice as great a crop as the same soil untreated when the two were afterwards cultivated in pots under similar conditions. In the same way an increased yield of 30 per cent. was shown when soil was first exposed to the vapour of such volatile antiseptics as carbon disulphide, chloroform, or toluene for 48 hours, provided that the soil was afterwards completely freed from the antiseptic before the experiment as to its fertility was commenced. The explanation was found to be that the protozoa and amœbæ of the soil which subsist on ammonia-producing bacteria are reduced or destroyed by heat or antiseptic treatment, and so the little engineers favourable to the fertile qualities of the soil are left unconsumed and unhindered to break down the complex nitrogen compounds into simple substances, of which ammonia is a type. By sparing the lives, in short, of the fertilising bacteria, by destroying their enemies the protozoa and amœbæ, the work of enriching the soil is encouraged. It is probable that the rays of the sun may also contribute towards checkmating the destruction of the beneficent bacteria by reducing the activities of the maleficent protozoa.

Bacterial Corrosion.

The active bacterium implies chemical action, and this is exemplified in a peculiar way in the corrosion of underground steel structures. The matter is of some importance in connexion with the stability of bridges and of the foundations of certain buildings. It appears that the corrosion of underground iron and steel may be due directly to the attack of a specific microbe, or indirectly to the action of bacteria creating acid conditions in the soil. It is suggested that underground steel structures should be protected against the acidogenic microbe by the free sprinkling of lime in the soil.

Sterilising by Light.

More than one article has appeared in our columns during the year referring to the development of ultra-violet rays as a practical means of destroying pathogenic organisms. The invention of the quartz or silica tube has made the production of ultra-violet light a practical quantity in the mercury vacuum lamp. The advantage of sterilising water intended for drinking purposes by using ultra-violet rays is obvious, since no chemical or physical alteration is effected. The method has been adopted for the domestic sterilisation of water on some practical scale. It remains to be seen how far the ultra-violet rays may be employed for the successful sterilisation of other substances.

Alcohol from Sawdust.

The production of ethyl alcohol from sawdust is a commercial consummation of well-known chemical principles. By converting the cellulose existing in all woody fibre into a fermentable sugar alcohol is readily obtained. As sawdust is produced in all parts of the world in enormous quantities in the cutting up of timber the industry promises to become an important one. The yield is about 30 gallons of alcohol, per ton of sawdust.

The Veterans of Chemical Science.

A remarkable gathering took place at the Savoy Hotel on Nov. 11th, 1910, on the occasion of a banquet given to the past presidents of the Chemical Society, who have been Fellows of that society for more than half a century. Those who bear the qualification were: Professor WILLIAM ODLING, F.R.S., the Right Hon. Sir HENRY E. ROSCOE, F.R.S., Sir WILLIAM CROOKES, O M., F.R.S., Dr. HUGO MÜLLER, F.R.S., and Dr. A. G. VERNON HARCOURT, F.R.S. Professor HAROLD B. DIXON, F.R.S., the present President of the Chemical Society, presided, and in giving the toast of "The Past Presidents who have been Fellows for Half a Century," paid a tribute to the immense services to science which each past president had rendered. The replies of the past presidents were most impressive, each recalling the special incidents of his career which have made them distinguished men in chemical history. With two sentences from Sir WILLIAM CROOKES'S reply we may aptly conclude as bearing upon the trend of recent chemical study. "Among the early speculations I heard propounded by FARADAY," said Sir WILLIAM CROOKES, "were those on the nature of electricity and the ultimate constitution of matter. In the highly rarefied regions of present-day speculation our progress is so rapid as to take away one's breath! It seems no law is more certain than the Law of Change. A bit of radium that would go into a thimble has almost suddenly shaken our belief in the conservation of substance, the stability of the chemical elements, the undulatory theory of light, and the nature of electricity; has revived the dream of the alchemists and the preservation of perpetual youth, and has cast doubts on the very existence of matter itself. For physicists are beginning to say that in all probability there is no such thing as matter; that when we have caught and tamed the elusive atom and have split it into 700 little bits, these residual particles will turn out to be nothing more than superposed layers of positive and negative electricity."

CONTRIBUTIONS FROM "THE LANCET" LABORATORY.

Two important inquiries, involving considerable experimental work, have occupied the attention of the laboratory during the year, but the results are not yet ready for publication. It is hoped, however, that the reports will appear in our columns early in the new year. One investigation relates to the quantity and character of the soot-fall in various parts of the metropolis under varying conditions of weather and at different seasons of the year; and the second investigation has produced some novel and interesting observations on the chemistry of the cup of tea in relation to its physiological effects.

Last year, it will be remembered, we published the report of THE LANCET Commission on the Standardisation of Disinfectants. Further work is still being done as time permits, and in THE LANCET of May 7th some improvements as to chemical analysis of disinfectants were recorded. More recently the substitution of iodine for bromine in the estimation of the replacement value of phenols has been worked out in the laboratory, the advantage of using iodine instead of bromine being that the point of saturation can more readily be seen when using the former element than when using the latter. During the year several well-known manufacturers have asked us to examine their disinfectant products in the light of THE LANCET test. Subsequently

we decided to open a column for reporting the results, the first example of which appeared in THE LANCET of June 11th. We note with satisfaction that certain well-known bacteriological authorities are adopting THE LANCET test.

In April last the Local Government Board issued a report upon the manufacture of rag-flock. It was satisfactory for us to find that Dr. REGINALD FARRAR'S observations, supported by reports from Mr. CECIL WARBURTON, Professor G. H. F. NUTTALL, Dr. G. S. GRAHAM-SMITH, and Dr. F. C. GARRETT, amply justified the terrible conclusions arrived at by THE LANCET Commissioners in 1907, 1908, and 1909. The purifying effect of washing was demonstrated in a series of analyses made of washed and unwashed flock in THE LANCET Laboratory in January, 1909.

A note from the laboratory on black bread appeared in THE LANCET of Jan. 15th, in which it was pointed out that there was very little difference between the nutritive value of the wheat and the rye loaf. The observation had its origin in the curious fallacy which at the time was going the rounds of certain political squabblers to the effect that the term "black bread" implied a kind of famine food, whereas, as it was shown, in several civilised countries rye bread is just as much the staple and normal article of diet as is the white loaf in this country.

Attention was called in THE LANCET of Feb. 5th to a rapid method of making hams, bacon, and certain fishes appear to be smoked by applying to them a fluid called "Smoke Essence." A specimen of the essence was examined in the laboratory and it was found to consist chiefly of creasote, aniline dye, and a salt of iron. The generally ubiquitous boric acid appeared to be absent. The contention that such a mixture is harmless may be right, but that does not justify leading the customer to suppose that a bloater, a tongue, a rasher of bacon or ham, treated by this simple process, had been adequately cured by the operation well known as "smoking." There can be no question at all that the colour is added to complete the disguise, and the ingenuity of the inventor of the "essence" is unquestionable, having regard to the use of a salt of iron, which is calculated to give a side of bacon an appearance of natural rustiness.

Two special laboratory inquiries during the year related to the production of light alcoholic beers. The results appeared in THE LANCET of March 26th and May 21st respectively. It is interesting to record that in both cases well-known brewing firms were concerned in placing upon the market malt liquors which are practically "temperance" in character.

Several "new inventions" involving analytical work in the laboratory were reported upon during the year.

The question of bleached flour, which has for some time engaged the attention of our laboratory, has come before the notice of the Local Government Board, and we were glad to learn that Mr. BURNS has directed an investigation into the matter by one of the inspectors of the Foods Department of the Local Government Board. In THE LANCET of May 28th we published a note on a simple test for bleached flour which is within the reach of the man in the street to apply.

We have again submitted to analysis and examination a number of quack remedies, and the results have been communicated to our correspondents.

During the year the work of special inquiries in THE LANCET Laboratory involved the making of 68 analytical determinations, whilst the figures of analysis appearing in our Analytical Records column amounted to 137. A very considerable number of analyses has in addition been made in regard to the unfinished investigations already referred to.

GENERAL MEDICAL COUNCIL.

The work of the General Council of Medical Education and Registration has been regularly chronicled in our columns throughout the year. At both the spring and autumn meetings a great deal of useful business was transacted.

The *personnel* of the Council has been altered in several respects. Mr. ARTHUR TREHERN NORTON is now the representative of the Apothecaries' Society of London, Sir WILLIAM WHITLA represents the Queen's University of Belfast, Sir ISAMBARD OWEN is the representative of the University of Bristol, and Dr. ARTHUR NEWSHOLME, Principal Medical Officer of the Local Government Board, has been nominated as a Crown member.

The summer meeting of the Council lasted from Tuesday, May 24th, to Saturday, May 28th inclusive. The PRESIDENT in his address was able to report that the Legislature of Prince Edward Island had passed an Act enforcing a five years' course of study at an approved university or school of medicine on candidates for qualifying examinations conducted by its Medical Council. The Executive Committee of the Council accordingly agreed to recognise the diplomas as registrable in the Colonial List. This is a step towards that reciprocity between Canada and England which all must desire, and which will be obtained presumably, if the representative authorities in the several provinces of Canada can come to a decision leading to federal action in regard to medical registration within the Dominion.

An interesting feature of those sittings which dealt with penal business was the presence of the British Medical Association as plaintiffs; the Association was represented by Mr. J. SMITH WHITAKER, the medical secretary, and Mr. HEMPSON, the solicitor.

There was a valuable debate upon medical education, and a report of the Examination Committee recommending that the licensing authorities should give instruction to students in ophthalmology, otology, and diseases of the throat, and that every candidate should be examined practically in these subjects, was referred to the Education Committee for consideration. At the winter session the Education Committee reported in recommendation of the practice of giving specialised instruction in otology and diseases of the throat. But the Committee did not think, in the present crowded state of the curriculum, that special courses and examinations should be made obligatory. They took the view that the subject should be included under the general headings of medicine and surgery.

The winter session commenced on Tuesday, Nov. 22nd, and terminated on Saturday, Nov. 26th. At this session the report of the Pharmacopœia Committee was adopted and showed that the annual sale of the Pharmacopœia continued steady as well as large, so that the volume will have to be reprinted.

The report of the Anæsthetics Committee, which was received by the Council at this meeting, was an important one. The Privy Council had transmitted to the General Medical Council for consideration a Memorandum and draft Bill, submitted to the HOME SECRETARY by Dr. FREDERIC HEWITT. The Memorandum discussed at length various points arising out of the administration of anæsthetics and suggested the rough draft of the Anæsthetics Bill, which was forwarded by the Privy Council and which will be found in THE LANCET of Dec. 3rd, 1910 (p. 1624). The Anæsthetics Committee recommended upon this Bill that the General Medical Council should communicate to the LORD PRESIDENT of the Privy Council certain observations on the draft Bill with most of which the whole medical profession will be in accord. The Committee found that the Bill gave practical effect to previous conclusions of the Council on the subject, and stated that they hoped it would speedily receive the

sanction of Parliament, while the Council would be prepared to suggest the terms of the necessary schedule specifying the drugs or substances described as anæsthetics, "including therein in the first instance nitrous oxide gas." The recommendations pointed out that the Bill did not provide for the prohibition of the application or administration by unqualified persons of dangerous anæsthetic drugs to unbroken surfaces; while the following recommendation led to some debate:—"That it is desirable that a provision should be introduced making it clear that a person registered under the Dentists' Act, 1878, is not prohibited from administering for a legally qualified medical practitioner one or more of the scheduled anæsthetics in connexion with an operation, act, or procedure other than dental conducted by such medical practitioner." This recommendation of the Anæsthetics Committee appears to us a little dangerous, and we fail to see for whose benefit it was made. The fact that the subject of anæsthetics is now regularly taught to all medical students ought to ensure a supply of medical men able to give gas for operations other than dental, while the patients to whom the dentist would be empowered by the recommendation in question to give gas would very often be in a different physical condition from that of the subject requiring dental forms of operation. We hope that the General Medical Council, whose opinion the Privy Council is certain to take, will reconsider this recommendation, though the matter is possibly not so important as some seem to believe, inasmuch as the dentist will not often be asked to discharge his suggested function.

An interesting debate at this session began in a proposal by Dr. H. A. LATIMER that the subject of professional ethics should be made an integral part of the medical curriculum. The motion was withdrawn, but we consider that Dr. LATIMER did good service in bringing the subject forward, for the discussion showed that the General Medical Council, the disciplinary body of the profession, were alive to the fact that positions might arise in professional life of considerable difficulty to the young medical man.

The last debate of the session was initiated by a report presented by Dr. J. Y. MACKAY from the Education Committee, which dealt with the medical curriculum and the preliminary education. The report was due to the resolution passed by the Council on Nov. 26th, 1909, referring to the Education Committee further consideration of the place in the student's career which the preliminary sciences should occupy. The committee was at the same time requested to frame and submit to the Council a pattern scheme of medical education whereby the required minimum of the several subjects to be included in the curriculum could be adequately studied and the requisite examinations thereon passed within the period prescribed by the curriculum. The report of the Education Committee accordingly furnished the Council with statistics as to the number of candidates who had sat at the first professional examination of the Conjoint Board of England on the strength of the school curriculum alone. It pointed out that the Conjoint Board, while recognising instruction in the preliminary sciences in institutions other than universities and medical schools—which they had done for 16 or 17 years—had only received for the first professional examination a very small proportion of students instructed in this manner, and this proportion came from the best schools of the country. The Education Committee considered that it was practically impossible to expect that the ordinary schools could at present take up the work of preparing schoolboys for the preliminary scientific examination of the medical curriculum. The report did not discuss the question whether the General Medical Council ought to recognise the schools which the Conjoint Board had already recognised, while in regard to the second matter referred to them they came to the conclusion that they could not determine upon a pattern scheme. Dr. MACKAY moved the adoption by the Council of the recommendation of the Committee, which was in the following terms: "That on and after the close of the year 1913 the following examinations be removed from the list of the preliminary examinations recognised by the Council as qualifying for entrance on the curriculum in medicine: The Junior Local Examination of the University of Oxford; the Junior Local Examination of the University of Cambridge; the College of Preceptors Preliminary Examination for Medical Students; the Educational Institute of Scotland Preliminary Examination; the Royal College of Physicians and Surgeons of Ireland Preliminary Examination; the Intermediate Education Board of Ireland Middle Grade Examination." At this point Sir HENRY MORRIS delivered an interesting speech, at the close of which he said that he was prepared to move the following: "That as the Education Committee in their report of Nov. 22nd, 1910, express views in favour of retaining the preliminary sciences (chemistry, physics, and biology) as subjects of the medical curriculum, it be referred to the Committee to consider and report to the Council as to the best way of amending the regulations of the General Medical Council in regard to the registration of medical students, with the objects (1) of making those regulations consistent with the report and with the powers of the Council; (2) of making clear the distinction between regulations which must be observed and recommendations made for the students' guidance; and (3) of the advisability of altering or deleting Regulation 12 on page 14 of the regulations printed under date June 1st, 1910." It was agreed to defer this motion until the summer session of 1911, while the recommendation of the Education Committee was adopted with the addition that communication would be made with the Commissioners of Intermediate Education in Ireland as to the possibility of establishing a satisfactory preliminary examination in education under the control of the Commissioners, which would be suitable to students intending to study medicine; an addition which was agreed to at once, as there is nothing in Ireland comparable to the leaving certificate in English schools. The recommendation of the Education Committee, which has now been adopted by the Council, will be welcomed by the schools as an educational advantage.

THE BRITISH MEDICAL ASSOCIATION.

The annual meeting of the British Medical Association took place this year in London under the presidency of Mr. BUTLIN, and was in every way a successful meeting. A large number of members attended the general gatherings, and the scientific work in the sections was made the subject of some interesting debates. The number of sections—namely, 21—was the largest as yet attempted, but the arrangements for the conduct of business were good and the necessary organisation worked well. All the sections could be accommodated in quarters which were in easy communication with each other, a matter of no small importance, as those who attend congresses know. The Representative meetings, which began on Friday, July 22nd, a week previous to the official date of the commencement of the annual meeting, were carried on in the chamber of the Court of Common Council in the Guildhall. At the opening meeting Mr. EDMUND OWEN, as Chairman of the Council of the Association, was able to announce the acceptance by His Majesty the KING of the post of Patron. Among the subjects debated by the Representatives at the meeting were Athleticism in Schools, the Organisation of a National Public Health Service, and the question of Poor-law Reform. The work of the sections and the official business of the Congress were conducted

in the buildings of the University of London, the Imperial Institute, the Imperial College of Science, and at the old College of Science, South Kensington—a group of buildings in close connexion with each other and allowing for easy arrangement of joint meetings when necessary, while medical men whose special interest lay, as often will happen, in several sections were able with a minimum of trouble to be present at each section as they wished. At the Annual Exhibition of drugs, surgical and electrical appliances, and special foods, which was held in the Imperial Institute Buildings, a great variety of exhibits were inspected by the visitors, while a new plan for pathological and other specimens was organised by the division of the medical museum into a number of sections, each under the care of an expert honorary curator. This was recognised as a valuable innovation.

Among very interesting debates in the different sections upon subjects of general and almost popular interest may be mentioned—the Operative Treatment of Simple Fractures, opened by Mr. ARBUTHNOT LANE; the Dosimetric Administration of Chloroform, opened by Dr. DUDLEY BUXTON; the Causes and Treatment of Dysmenorrhœa, opened by Dr. G. E. HERMANN; the Treatment of Chronic Constipation, opened by Dr. J. F. GOODHART; the Surgical Treatment of Exophthalmic Goitre, by Professor THEODORE KOCHER; State Sickness Insurance, opened by Mr. SMITH WHITAKER and Mr. C. S. LOCH; and the Need for Diplomas in Psychological Medicine, by Dr. D. G. THOMSON.

THE BENEVOLENT AGENCIES OF THE PROFESSION.

We review here, though very briefly, the work carried out by the benevolent agencies of the profession and remind our readers of their duty, which in the stress of professional work they sometimes forget, to see that the institutions which have been founded solely in their interests are adequately supported.

A large number of medical men who could easily afford to give an annual subscription of 1 guinea to one or more of the general benevolent societies do not contribute at all, as a glance at the reports of these societies will show, whilst the number of practitioners who could contribute a smaller subscription without feeling the loss, but who do not do so, is very much larger. We once again urge our readers to bear the claims of these benevolent agencies in mind, and to show their appreciation of the good work carried out in a practical manner. But whilst the general societies carry on a work the importance of which is increasing every year, it is the local institutions which we especially wish to see better supported, in view of the fact that relief can usually be obtained from them so much more expeditiously than in the case of large general societies, the grants made being frequently more or less substantial according to the needs of the cases.

So far as we can learn, there is not a single medical benevolent association in either Scotland or Wales, and the same must be said of many counties in England. Whilst acknowledging that there are generous contributors to the general medical charities living in these places, we feel that this deficiency in the scheme for the relief of necessitous members of our profession and their families ought not to be allowed to continue, and we look forward to the time when enthusiastic volunteers in these districts will take steps to inaugurate associations, and thus emulate the example of those who many years ago worked indefatigably to establish much-needed benevolent societies. The two latest accessions, the East and North Ridings of Yorkshire Medical Benevolent Society, founded in 1908, and the Sussex Medical Benevolent Society, founded in 1905, are both making satisfactory progress.

What is urgently required in the case of all benevolent agencies is zealous personal canvassing, together with explanation of the work that is being carried out. As a rule, printed letters of appeal prove of little use, hence the appointment of suitable local secretaries is to be strongly advocated.

The British Medical Benevolent Fund.

The report of this society is exceedingly favourable. The income in the grant department exceeded that of the previous year by £543, and in the annuity department by £83. Grants were made to 200 applicants, as compared with 185 the preceding year, the total amount expended in this way being £2078, as against £1727 in 1908. The sum received in legacies was £13,419. There are 127 annuitants, the large majority of whom receive £20 a year, the total amount expended in pensions being about £2520 annually. The Guild recently founded in connexion with the Fund, which is practically the ladies' branch of the society, is doing good work in the way of distributing clothes, visiting the beneficiaries of the Fund, and rendering other services of a personal character.

The Royal Medical Benevolent Fund Society of Ireland.

The treasurer's report shows that grants were awarded to 86 applicants, amounting in the aggregate to £1438, as compared with £1166 awarded to 83 applicants during the preceding year. In only one year since the foundation of the society have the grants awarded exceeded those of the year under review. Of those helped during the year, eight were between 70 and 80 years of age, and four were older still. The President of the Royal College of Physicians of Ireland, in moving the adoption of the report at the annual meeting, emphasised the fact that the religious beliefs of applicants had never been mentioned or considered in any way by members of the committee when recommending a grant. Simply the facts of the case were dealt with and if found deserving an award was granted.

The Royal Medical Foundation of Epsom College.

The annual report of the council states that there was a small surplus on the year's revenue. The fact is emphasised that in spite of past contributions to the endowment fund, including the sum of £51,076 recently received under the will of the late Dr. HENRY FEARNSIDE, a sum of nearly £5000 must be obtained by annual contributions if the council is to continue to maintain the full number of 50 pensionerships and 50 foundation scholarships. The pensions, which are all of £30 a year, are given by the governors to aged medical men or their widows. The foundation scholars, who are also elected by the governors, are necessitous sons of medical men, and receive an education of the highest class at Epsom College, together with clothing and board. The buildings have been extended and various improvements have been completed during the past few years at a cost of close upon £20,000, a considerable part of the money required being temporarily advanced by the bankers. Besides the pensionerships and foundation scholarships which are maintained out of the general funds, special endowments provide 28 other annuities of £30 a year, 14 supplementary pensions of £20 (to increase annuities to £50), and 11 presentations to the school of St. Anne's Society for daughters of medical men.

THE LANCET *Relief Fund.*

This Fund is sustained by an annual grant of at least £300 by the proprietors of THE LANCET, and is administered free of cost. The almoners are the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, the President of the General Medical Council, and the Editor of THE LANCET. The object of the Fund is to provide immediate pecuniary assistance in cases of emergency to registered medical practitioners, or in the event of their recent death to their widows

and orphans, but such help can only be rendered when permanent benefit is likely to result therefrom.

The twenty-first annual report of the almoners states that since the inauguration of the Fund in 1889 the sum of £6354 has been expended. During the year 1909 14 applicants were relieved by way of gifts or loans ranging from £10 to £25, involving an expenditure of £235. As usual, expressions of gratitude for the prompt assistance rendered were received by the almoners, such assistance having been given in some instances within a few hours of the receipt of the application; thus more than one home was kept together and the bread-winner enabled to continue to practise by the timely help of the Fund.

The Society for Relief of Widows and Orphans of Medical Men.

The report states that 16 new members were elected last year, 9 died, and 5 resigned. The total membership of the society is 291, which is but a very small proportion of the medical men who are eligible for membership. Considering that the invested funds amount to over £100,000, that the advantages offered are far greater than any that an insurance company could give, and that the subscription is only £2 2*s.* a year, it is difficult to understand why comparatively so small a number of medical men living within a radius of 20 miles from Charing Cross join this society. It may be added that one of three widows who died during the year under review had received a total sum in grants of £2900, in spite of the fact that her husband had paid in subscriptions only £6 6*s.* Further, one of the widows at present on the books has already received, since her election in 1854, over £2250.

Complete List of Benevolent Agencies.

For the information of our readers we give the name and address of the secretary or other executive officer of all the benevolent agencies of which we are cognisant, together with the amount of the subscription that entitles to membership:—The British Medical Benevolent Fund: Mr. W. E. SARGANT, St. Bartholomew's Hospital, E.C.; annual subscription 10*s.*, life donation £5. The Birmingham Medical Benevolent Society: Dr. J. E. H. SAWYER, 93, Cornwall-street, Birmingham; annual subscription 1 guinea. The Devon and Exeter Benevolent Medical Society: Mr. E. DOWN, Wingfield House, Stoke, Devonport; annual subscription 1 guinea, life donation 20 guineas. The East and North Ridings of Yorkshire Medical Benevolent Society: Dr. EDWARD TURTON, 1, Albion-street, Hull, and Mr. H. C. SHANN, Micklegate House, York; annual subscription 1 guinea. The Essex and Herts Benevolent Medical Society: Mr. VERNON AUSTIN, Hertford; annual subscription 1 guinea. The Kent Benevolent Medical Society: Mr. H. G. SADLER, J.P., 2, De Castro-terrace, Wincheap, Canterbury; Dr. C. E. HOAR, Montcalm, Maidstone; and Mr. H. C. BURTON, Lee Park Lodge, Blackheath, S.E.; annual subscription 1 guinea. THE LANCET Relief Fund, Mr. CHARLES GOOD, 1, Bedford-street, Strand, W.C. The Lincolnshire Medical Benevolent Society: Dr. W. A. CARLINE, Lincoln; annual subscription 1 guinea. The Norfolk and Norwich Benevolent Medical Society: Mr. C. J. MURIEL, 42, St. Giles-street, Norwich; admission fee 1 guinea, annual subscription 1 guinea, life donation 15 guineas. The Royal Medical Benevolent Fund Society of Ireland: Dr. CHARLES M. BENSON, 65, Lower Baggot-street, Dublin; annual subscription 1 guinea, life donation £10. The Royal Medical Foundation of Epsom College: Mr. J. BERNARD LAMB, 37, Soho-square, W.; annual subscription 1 guinea, life donation 10 guineas. The Society for Relief of Widows and Orphans of Medical Men: Mr. E. J. BLACKETT, 11, Chandos-street, Cavendish-square, W.; annual subscription 2 guineas, life membership 25 annual payments. The Surrey Medical Benevolent Society: Mr. W. A. BERRIDGE, 158, Station-road, Redhill, Surrey; entrance fine £5, annual subscription £2 (not payable for longer than 30 years), life donation £30, *plus* the entrance fine of £5. The Sussex Medical Benevolent Society: Dr. L. A. PARRY, 83, Church-road, Hove, Sussex; annual subscription 1 guinea. West Riding of Yorkshire Medical Charitable Society: Mr. G. H. ROWE, Lyddon Hall, Leeds; and Mr. M. A. TEALE, 4, Park-square, Leeds; annual subscription 1 guinea.

The officials of the above-mentioned societies will be happy to forward to applicants full particulars of the work that is being carried out.

HONOURS TO MEDICAL MEN.

The compilation of the list of those members of the medical profession, who have been selected during the year for honours, is a pleasant task; this year, however, the feeling of sadness arises from the fact that the hand which gave the earlier honours can do so no more. His Majesty the late KING EDWARD VII. was always a friend of the medical profession, and whenever merit was brought to his notice he never failed to signify the royal approval.

The Birthday Honours.

In the list of honours which was issued on the day set apart for the celebration of His late MAJESTY'S birthday medical men were well represented, and the list gave particular pleasure to our profession because on this occasion another medical name was added to the roll of the peerage, Sir WALTER FOSTER being created Lord ILKESTON. Dr. FRANCIS HENRY CHAMPNEYS was made a baronet, and knighthoods were conferred upon Dr. ARTHUR HENRY DOWNES, Mr. JOHN FAGAN, Dr. GEORGE HASTINGS, Dr. HENRY SIMPSON LUNN, Dr. DAVID CALDWELL MCVAIL, Dr. ROBERT MICHAEL SIMON, Surgeon Lieutenant-Colonel WARREN ROWLAND CROOKE-LAWLESS, C.I.E. (Coldstream Guards), and Inspector-General of Hospitals and Fleets JAMES PORTER, C.B. Lord ILKESTON is well known in the world of general and medical politics. He was for nearly a quarter of a century professor of medicine in Queen's College, Birmingham; was for many years a Direct Representative of the profession on the General Medical Council, and has been a powerful voice in the administration of the British Medical Association. In Parliament he was a practical success from the beginning of his career, and a member of a Liberal Government. At the general election in the early part of the year he resigned his safe seat for the Ilkeston division of Derbyshire. Sir FRANCIS HENRY CHAMPNEYS is the chairman of the Central Midwives Board, on which body he has sat continuously since its creation. His distinguished work in obstetric medicine is well known. Sir ARTHUR HENRY DOWNES, the Senior Medical Inspector for Poor-law Purposes to the Local Government Board, whose honour was won by strenuous and devoted work, was the only medical man on the recent Royal Commission on the Poor-law. He showed in a practical way, by an independent memorandum, that he appreciated the tremendous importance of the issues involved alike from the public, the departmental, and the professional view. Sir JOHN FAGAN is consulting surgeon to the Belfast Royal Hospital and to the Belfast Hospital for Sick Children, and was for many years inspector of reformatory and industrial schools for Ireland. Sir GEORGE HASTINGS is a well-known West-end practitioner; Sir HENRY SIMPSON LUNN is one of the great pioneers of continental travel; Sir DAVID CALDWELL MCVAIL is Crown member for Scotland of the General Medical Council and an authority on medical politics and education; and Sir ROBERT MICHAEL SIMON

is physician to the Birmingham General Hospital. Lieutenant-Colonel Sir WARREN R. CROOKE-LAWLESS is surgeon to H.E. the Viceroy of India, and Sir JAMES PORTER, K.C.B., is the Director-General of the Medical Department of the Royal Navy. Surgeon-General ARTHUR THOMAS SLOGGETT, A.M.S., C.M.G., Principal Medical Officer in India, and Surgeon-General OWEN EDWARD PENNEFATHER LLOYD, R.A.M.C., V.C., Principal Medical Officer in South Africa, were made Companions of the Order of the Bath; and Surgeon-General CHARLES PARDEY LUKIS, honorary surgeon to the Viceroy of India, Director-General of the Indian Medical Service, and an additional member of the Council of the Governor-General of India for making laws and regulations, received a Companionship of the Order of the Star of India. Dr. AUBREY DALLAS PERCIVAL HODGES, Principal Medical Officer in the Uganda Protectorate, received a Companionship of the Order of St. Michael and St. George in recognition of his services in the suppression of sleeping sickness. Colonel RODERICK MACRAE, I.M.S., lately Inspector-General of Civil Hospitals in Bengal, received a Companionship of the Order of the Indian Empire; and Captain ROBERT MCCARRISON, I.M.S., Agency Surgeon at Gilgit, and Dr. THEODORE LEIGHTON PENNELL, medical missionary at Bannu, North-West Frontier Province, received the Gold Medal of the Kaisar-i-Hind.

The Royal Victorian Order.

During the year Sir ALFRED PEARCE GOULD and Sir J. KINGSTON FOWLER were invested with the insignia of a Knight Commander of the Royal Victorian Order, and Fleet-Surgeon GEORGE TREVOR COLLINGWOOD, R.N., of the Royal Naval College, Osborne, was appointed a Member of the Fourth Class. Professor ROBERT KUTNER, Director of the Empress Frederick's Institute for Medical Education in Berlin, was appointed an Honorary Commander of the Order.

The Edward Medal.

The Edward Medal (Second Class) was presented to Mr. E. A. DANDO, Dr. CHARLES HARRIS, and Mr. W. TURNER. This honour was instituted by His late MAJESTY in order to distinguish the many heroic acts performed by civilians who endanger their own lives in endeavouring to save the lives of others.

Foreign Honours.

The KING of ITALY conferred the Order of Commander of the Crown of Italy upon Major G. S. CRAWFORD, R.A.M.C., and Knight of the same Order upon Captain H. S. ANDERSON, Captain H. C. WINKWORTH, and Captain P. A. JONES, of the Royal Army Medical Corps, and Surgeon-Captain R. RANDON, Royal Malta Artillery, in recognition of their services with the field ambulances which proceeded from Malta to the earthquake disasters in Sicily and Calabria in the early part of last year. Surgeon JAMES C. BRINGAN, R.N., also received the decoration of a Knight of the Order of the Crown of Italy in recognition of valuable services rendered by him on the occasion of the Messina earthquake. Dr. JOHN WARNOCK, Director of the Government Hospital for the Insane at Abbassia, received the Insignia of the Third Class of the Imperial Ottoman Order of the Osmanieh from the KHEDIVE of EGYPT, and Captain H. ENSOR, D.S.O., R.A.M.C., received the Insignia of the Fourth Class. Dr. EDWIN ROBERT WHEELER, medical officer to the British Consulate-General at Yokohama, received the Order of the Sacred Treasure of the Third Class, which was conferred upon him by His Majesty the EMPEROR of JAPAN; and Dr. HUGH CAMPBELL HIGHET, medical officer of health at Bangkok, received the Order of the White Elephant of the Third Class from His Majesty the KING of SIAM. Mr. B. C. BROOMHALL and Dr. E. H. EDWARDS have each received the Insignia of the Third Class of the First Division of the Imperial Chinese Order of the Double Dragon conferred upon them by the EMPEROR of CHINA.

HOSPITAL FUNDS.

Metropolitan Hospital Sunday Fund.

Under the presidency of Sir JOHN STUART KNILL, Bart., the late Lord Mayor, the year's collection reached a total of £71,550 8*s.* 8*d.*, the collections in the various places of worship amounting to £40,778, or £1635 more than in 1909. The Metropolitan Cathedral of St. Paul headed the list with £4483. The following are the largest collections from contributing churches and other places of worship:—Christ Church, Lancaster Gate, Rev. Prebendary GURDON, £951; St. Michael, Chester-square, Rev. J. GOUGH MCCORMICK, £721; St. Mary Abbots, Kensington, Rev. Prebendary PENNEFATHER, £493; St. Peter, Eaton-square, Rev. Prebendary STORRS, £486; Holy Trinity, Chelsea, Rev. H. R. GAMBLE, £465; St. George, Hanover-square, Rev. Prebendary ANDERSON, £345; St. Jude, South Kensington, Rev. Prebendary EARDLEY WILMOT, £331; St. Paul, Onslow-square, Rev. Prebendary WEBB-PEPLOE, £308; St. Paul, Knightsbridge, Rev. F. L. BOYD, £296; St. Mark, North Audley-street, Rev. H. P. CRONSHAW, £289; St. Peter, Cranley-gardens, Rev. W. S. SWAYNE, £282; St. John, Paddington, Rev. E. P. ANDERSON, £270; St. Nicholas, Chislehurst, Rev. J. LE STRANGE DAWSON, £266; Wimbledon Churches, Rev. J. ALLEN BELL, £205; St. Columba, Pont-street, Rev. A. FLEMING, D.D., £282; Theistic Church, Swallow-street, Rev. CHAS. VOYSEY, £204; West London Synagogue, Rev. M. JOSEPH, £331; Great Synagogue, the CHIEF RABBI, £239; Essex Church, Kensington, Rev. F. K. FREESTON, £274; Westminster Chapel, Rev. G. CAMPBELL MORGAN, £300; Brixton Independent Church, Rev. B. J. SNELL, £117; St. Paul's Presbyterian Church, Westbourne-grove, Rev. J. W. WALKER, £93; St. Andrew's Presbyterian Church, Frognal, Rev. R. MACLEOD, £130; Greek Church, Bayswater, the ARCHIMANDRITE, £91; Brompton Oratory, Rev. H. D. S. BOWDEN, £87; Church of the Immaculate Conception, Farm-street, Rev. C. NICHOLSON, £55; Victoria Park Christian Evidence Association, Mr. T. COLE, £60; Dutch Church, Austin Friars, Rev. S. B. DE LA FAILLE, £50; German Church, Camberwell, Rev. Professor HACKMANN, £52; Central Hill Baptist Church, Norwood, Rev. S. A. TIPPLE, £95; Wanstead Society of Friends, Mr. THEO. GODLEE, £27; Bromley, Kent, Wesleyan Church, Rev. W. WOOD, £35; and Gordon-square Catholic Apostolic Church, Mr. H. S. HUME, £30. From the estate of the late Mr. GEORGE HERRING the Fund received £26,903, and Mr. WILLIAM HERRING gave a donation of £1000. The expenses of management amounted to £3420; £4629 have been carried forward to next year, and the following sums have been awarded, viz.: £58,189 to 153 hospitals, £1047 to 12 institutions, £2270 to 59 dispensaries, and £1575 to 30 nursing associations. For surgical appliances the sum of £4640 has been appropriated, and by reason of the increasing demand for these appliances the proportion of the funds devoted to this purpose—viz., 5 per cent.—has been advanced to 7½ per cent.

King Edward's Hospital Fund.

In many ways the hospital world has sustained a severe blow by the death of KING EDWARD VII., but the Fund which bears his honoured name has continued to make excellent progress, the amount received by the Fund up to Dec. 10th, after payment of expenses, being £146,584 10*s.* The Committee of Distribution have been able to allocate £150,000 to London hospitals and £5000 to consumption sanatoriums, making a total of £155,000, as compared with £150,000 last year. It is estimated that the League of Mercy will be able to contribute about £20,000. His

Majesty KING GEORGE, like all the members of our Royal Family, has always taken the keenest interest in any work that has for its object the welfare of the sick poor, and his deep interest in the Fund which was founded by the late KING is increasingly shown, not only by the letter which was read at the annual meeting of the Fund held at St. James's Palace on Nov. 14th, in which he expressed his appreciation of the services of the Council of the Fund, over which he has presided for nine years, but also by the augmentation of his annual subscription from £500 to £1000. An additional mark of the Royal interest in the welfare of the Fund is the annual subscription of £100 given by the PRINCE OF WALES. The receipts for the year include an annual subscription of £5000 from Mr. WALTER MORRISON and an anonymous donation of £10,000. The report of the Distribution Committee shows that 106 hospitals have applied for grants as against 104 last year, while the number of convalescent homes applying for grants was 45 and the number of consumptive sanatoriums eight, as compared with 37 and 4 respectively last year. The inability of the nose, throat, and ear hospitals of London to combine in accordance with the recommendation of the Fund has resulted in a sum of money being set aside for these hospitals until such amalgamation takes place. The total sum held in reserve for this purpose now amounts to £7500, in addition to the capital grant promised by the Fund, which, under certain conditions, will amount to at least £10,000. An interesting feature of the report is the statement that a scheme has been prepared by the Convalescent Homes Committee for rendering a certain number of beds in consumption sanatoriums in the country available for patients direct from London hospitals, more especially from consumption hospitals which have no country branches of their own. The Distribution Committee has always viewed with special satisfaction the facilities possessed by consumption hospitals which have country branches for the transfer of suitable cases to surroundings more favourable to recovery; and it welcomes any practicable method by which more of such accommodation can be rendered available without charging the funds of a hospital with the necessity of providing for a large capital expenditure. Another matter of interest is the reference to coöperative purchase by groups of independent hospitals, a matter which has not been lost sight of by the Fund. Reference is also made in the report to the grant to St. George's Hospital which is withheld until the financial accounts between the hospital and its medical school are shown to be clear of any payment from the general funds on account of medical education. At the same time it is pointed out that the inquiries made by the committee as to the legitimacy of certain payments by the hospital out of general funds to the medical school confirm the statement in the annual report of the hospital that the payments in question were made on account of definite work done, chiefly pathological and bacteriological examinations, in connexion with the actual treatment of patients.

A committee consisting of Lord MERSEY as chairman, Lord NORTHCOTE, and the Bishop of STEPNEY has been appointed to consider the hospital out-patient question and will commence work early next year. The following are the terms of reference: "To consider and report generally as to the circumstances and conditions under which patients are admitted to the casualty and out-patient departments of the London voluntary hospitals, and especially as to what precautions are taken to prevent the admission of persons who are unsuitable, and as to whether adequate provision is made for the admission of such persons as are suitable; and to make such recommendations as may seem to them desirable." During the year the KING selected the Duke of TECK, Lord IVEAGH, and the Speaker of the House of Commons to be governors of the Fund until the time arrives when a new Royal President can be appointed.

Hospital Saturday Fund.

The annual income of the Hospital Saturday Fund, which was founded in 1873 for the purpose of obtaining help for the metropolitan hospitals and kindred institutions from those who were not reached through the operations of the Metropolitan Hospital Sunday Fund, now exceeds £30,000, which is obtained from some 8000 places of business. The annual report shows that help is obtained from practically every trade, friendly society, and club, the employés of the London County Council, the borough councils, the railway companies, the Metropolitan Water Board, the General Post Office, the Royal Arsenal, Woolwich; the Royal Small Arms Factory, Enfield Lock; the Royal Victoria Yard, Deptford; the Dock Companies, and so forth, and the members of the Metropolitan and City police. Since its foundation the Fund has collected and distributed among the medical charities of London £517,106. In recent years there have been about 200 participating institutions. The Fund, recognising the great importance of early treatment in cases of tuberculosis and other chest diseases, has endowed beds at the Benenden Sanatorium, Kent; at the Mount Vernon Hospital, Hampstead, and its sanatorium at Northwood; at the Fairlight Home, Hastings; and at the Eversfield Hospital, St. Leonards. Thirty-seven beds are at present endowed, the patients paying, as a rule, 7*s.* 6*d.* per week for the first six weeks, after which time the prices are arranged in accordance with the means of the patients and other circumstances. The sum thus received enables the Fund to assist many applicants who could not otherwise be relieved. During the present year the various departments of the Fund have made steady progress, and it is hoped that when the books are made up in January they will show a record collection for 1910. Up to Dec. 17th the total receipts of the Fund amounted to £23,536, as against £20,765 in the corresponding period of 1909.

THE ORGANISATION OF THE MEDICAL PROFESSION: LESSONS FROM ABROAD.

At the commencement of the year we reviewed the situation of the medical profession in regard to the organisations by which medical men might hope to defend their economical interests while upholding the dignity of the profession. The fact that insurance against sickness is compulsory in Germany and Austria has established the contract system by force of law throughout these two empires. This system is extending to other countries, and something similar may ultimately be adopted in Great Britain. Therefore the action taken by the medical profession abroad is of great and practical interest to us in this country, and we described the strength of the continental medical unions, alluding at the same time to some of their more notable struggles or strikes. Since the publication of these details perhaps the most cheering item of news was that relating to the admirable conduct of the members of the Medical Union of the Seine who were in practice in and about Paris during the great floods. The union at once passed a resolution placing all its funds at the disposal of medical men injured by the floods. Circulars offering financial help were sent out to 4000 medical practitioners, and the union foresaw the early depletion of its coffers. The very reverse happened. Of all the 4000, not one asked for anything for himself; but, on the other hand, many practitioners, several of them not belonging to the union at all, sent donations to the Medical Union funds, so as to assist in the work of relief. And though no medical man asked for help for himself, several practitioners

wrote describing the very distressful condition of some of their comrades, and suggested that they should be assisted. Not only were the furniture and belongings of many practitioners destroyed by the floods, but many of their patients were also financially damaged, if not ruined, so that the fees owing were not at all likely to be paid.

TOWN PLANNING AND RE-HOUSING: THE LESSON OF LIVERPOOL.

The ideas underlying the systematic planning of towns have been concretely realised at Liverpool, and we made a special investigation of the position there. Considering that at Liverpool the average death-rate for the ten years concluded in 1870 was 32·5 per 1000, and that this has now been reduced to less than 20 per 1000, there can be no doubt but that great sanitary improvements have been accomplished. Indeed, among these ameliorations may be mentioned not only the destruction of insanitary areas in central and congested districts, but the fact that the authorities did not wait for the Town Planning Act to take measures to prevent the creation of overcrowded districts in the as yet uninhabited surroundings of Liverpool. New thoroughfares, preserving fine old trees and varying in width from 80 to 114 feet, were described by our Sanitary Commissioner as having for their object not merely the securing of ample air and garden space for future dwellers, but as also aiming at lessening the vehicular traffic in the central parts of the city. For the present, in most instances 35 feet will suffice for carriage traffic and tram lines, so that the rest will be devoted to trees, side walks, and flower beds. Such will be the pleasant and wholesome character of the main thoroughfares of Greater Liverpool. This phase of the town planning, however, concerns the near future and does not explain the actual reduction in the death-rate, and the fact that the Liverpool slums are no longer the classic haunts of typhus fever, drunkenness, immorality, and crime also plays its part in a beneficent revolution. The descent in 1845 of some 80,000 Irish flying from the potato famine made the slums of Liverpool exceptionally bad that in one or two districts the death-rate was equal to 60 per 1000 per annum. To meet these evils an Act for the promotion of health in Liverpool was passed in 1846. Nothing else, however, was done; but in 1854 there was another Act preventing the construction of houses of a low type, though, unfortunately, very many such houses were already in existence. The next ten years marked no advance, but a local Act gave the corporation powers to acquire insanitary property in 1864, and much of the re-housing of Liverpool was carried out under this Act. The Act specified what sort of houses might be condemned, the details being presented to the grand jury at quarter sessions. After hearing the owner, the jury might sanction the pulling down of the houses, and the corporation could buy the land if, as was usually the case, the owner was willing to sell. Thus the city came to own much of the land on which the slums stood, and care has, of course, been taken that no more slums were built. But it was slow work. Of 22,000 houses that should have been condemned in 1864 only 7000 were actually demolished by 1883. One difficulty lay in the fact that only the bad houses and not the surrounding area could be demolished, and it was only later, under the Housing of the Working Classes Act of 1890, that whole areas could be dealt with. By the year 1902 a house-to-house inspection revealed the existence of still 9943 houses which were fit only for demolition. The Local Government Board, however, would not sanction further loans for this purpose until better re-housing provisions were made. Indeed, it is only recently that the policy of re-housing has become an integral part of the policy for dealing with insanitary areas, so that it took 20 years for re-housing reforms to get fairly under way. Now the corporation owns and lets more than 2000 tenements, which have over 5000 rooms and are occupied by some 8000 persons. The rents vary from 1*s*. 9*d*. per week for one-room tenements to 4*s*. 9*d*. to 5*s*. 6*d*. for three-room tenements. But there are thousands of families in Liverpool who have to subsist on 10*s*. a week; and among the poorer sections of the community for whom these housing schemes are intended 15*s*. to £1 a week is the exception rather than the rule. The rents for the corporation tenements are below the market value of such dwellings, therefore no tenant is admitted unless he can show that he inhabited formerly a house that had been demolished by the sanitary authority. The remarkable feature of the work accomplished more recently in Liverpool is the fact that the re-housing schemes have led to an awakening of self-respect and endeavour among the most forlorn section of the population which has not only reduced the death-rate of the city, but has also had a favourable influence on the statistical returns for crime, drunkenness, and assault.

THE EDINBURGH CONFERENCE ON TUBERCULOSIS.

The National Association for the Prevention of Tuberculosis made a new departure this year, for instead of holding its annual meeting in London it organised a Conference in Edinburgh. For some days before and after this Conference numerous meetings were held and lectures delivered all for the purpose of spreading instruction on whatever might help to prevent tuberculous diseases. In connexion with the Conference there was also a small exhibition, and numerous popular lectures were delivered, and by these means a good deal of valuable knowledge was disseminated among the population of Edinburgh. We reported the congress at considerable length. Some of the papers were excellent, and we published several of them in full and gave summaries of many others, but a good many of the communications had little reference to the subjects opened for discussion. There was a good discussion on the question of the treatment of tuberculosis among the working classes, and the possibility of State intervention was brought forward. The inadequacy of the measures taken in this country was indicated by the statement that there were only some 4000 beds in hospitals and asylums, and 3350 in Poor-law institutions available for the treatment of tuberculosis; about 7350 beds for perhaps 22,000 patients in the course of a year. But it is estimated that there are 60,000 new cases every year and some 350,000 cases remaining over from previous years. Consequently there is an estimated need of 30,000 beds more, and about £3,500,000 for preventive and curative treatment, and £3,000,000 for advanced cases, making a total annual tuberculosis budget of £6,500,000. No private charity can possibly cope with such a demand. A motion brought forward by Dr. J. C. MCVAIL was unanimously adopted calling the special attention of the Chancellor of the Exchequer, the Government, and Parliament to the importance of giving the prevention and treatment of tuberculosis a prominent place in the proposed scheme of invaliding and insurance.

SANITATION AND THE FEDERATION OF THE "SIX TOWNS."

After much dispute and delay the "Six Towns," once known as the "Five Towns," have been united in law as well as in fact. Formerly Burslem, Fenton, Hanley, Longton, Stoke, and Tunstall were separate places with very individual characteristics. But, enriched by the development of the Potteries, they have spread till they commingle, and obviously a single administration for what has become an

unbroken agglomeration of dwellings will be more effective and economical. It is not always easy to do the logical thing, and the people of the Potteries found this out when they set about to abolish six town councils, six town clerks, six medical officers of health, six borough surveyors, and many other functionaries who had served, some of them long and faithfully, their different municipal administrations. In spite of these and other difficulties, however, the new borough of Stoke-on-Trent came into existence on March 31st. There is only one borough council, but it has 104 members, representing a quarter of a million people. Such complex questions were bound to arise out of this sudden conversion of six towns into one that our Special Sanitary Commissioner went down to investigate the position as it affected public health, for there were six different systems of drainage and of sewage disposal. We were able to publish figures which showed that the incidence of typhoid fever and summer infantile diarrhœa coincided with the survival of privy cesspools and other insanitary closets. Thus, at Longton, in four years, there were 99 deaths from enteric fever. About a third of the houses had water-closets, yet only 7 of these deaths occurred in these houses, while the other 92 deaths took place in houses with insanitary domestic drainage, including 33 cesspools. At Hanley, fortunately, the cesspool system is, practically speaking, abolished. There are only 70 cesspools, while there are 6760 water-closets with proper flushing cisterns and 4000 cottage basin hand-flushed closets which are usually sanitary in construction but depend on the trouble taken to keep them in decent order. Wherever the system of drainage has been improved the infantile mortality has decreased, though it is still very high. This has been sometimes attributed to lead poisoning, but, at Longton, for instance, only 25 per cent. of the mothers in question went to work at the potteries where lead is employed. Also the greatest mortality occurs during the hot weather, and this is when insanitary conditions make themselves felt, while lead is as fatal in winter as in summer. The difficulty is to induce the adult workers to take the necessary precautions when handling the lead used to glaze china ware, and to teach mothers how to nurse and feed their children and keep them clean. One of the first results of amalgamating the six towns should be to systematise the distribution of water and to reduce its cost. This will greatly facilitate the abolishing of cesspools or privies and the substitution of cistern-flushed water-closets. Then the small, inefficient public abattoir which the town of Hanley built some time ago should be replaced by a large modern abattoir containing all the latest improvements, where not only would all the slaughtering be done under wholesome conditions, but the by-products treated in such a manner as to prevent any nuisance, while adding considerably to the profits of the undertaking.

OBITUARY.

From the beginning of this year up to and including our issue of Dec. 24th we have had the mournful duty of inserting in our columns special obituaries of well-known and highly appreciated medical men. With deep regret we also had to record the death of KING EDWARD VII. To the profession of medicine he was a staunch and helpful friend. In a brief biographical sketch we enumerated many occasions on which he publicly showed his appreciation of medicine and his certainty that in its scientific practice lay the solution of many of the social problems of the day.

Dr. T. DIXON SAVILL died at Algiers on Jan. 10th as a result of a fall from his horse and a fracture of the skull at the age of 53 He was physician to the West-End Hospital for Diseases of the Nervous System, and his various contributions to medicine proved him to be a man of great originality and knowledge. He was for many years a regular correspondent of THE LANCET, summarising for us the scientific debates at the more important medical societies. Dr. JOHN HOLMES JOY, who died on Jan. 4th, was a prominent practitioner of the Midlands. He was born in Dublin in 1842. He seems to have had an hereditary or intuitive knowledge of law, which made his work as a Commissioner of the Peace very valuable. Dr. GEORGE MORTON WILSON, who died on Jan. 6th, was a pioneer of the open-air treatment of tuberculosis. His sanatorium, opened about ten years ago, was one of the first three sanatoriums for Nordrach treatment in England. Dr. GEORGE SKENE KEITH died at the great age of 90, the attainment of which he himself attributed to his adoption of the simple regimen laid down both in his two essays entitled, "Fads of an Old Physician" and "A Plea for a Simpler Life," and in his "Papers on Sanitary and Other Matters," which made a considerable stir some 15 years ago. Dr. WILLIAM PAGE MAY, who died on Jan. 19th, was a Fellow of University College, London, and lecturer on the physiology of the nervous system at the College. In addition to his high scientific attainments, he was known as one of the kindest and most delightful of men, and his loss is keenly felt by a wide circle of friends. Dr. STANLEY BEAN ATKINSON was born in 1873. Besides his medical qualifications he held the degree of LL.M. Cantab., and was a member of the Inner Temple. He devoted his life to public service and settled himself at Mile-End, where he interested himself in the social progress of its inhabitants. Mr. CONNELL WHIPPLE died on Jan. 21st in his sixty-eighth year. He was consulting surgeon to the South Devon and East Cornwall Hospital, having been an acting member of the honorary staff for about 35 years. Mr. WILLIAM WARWICK WAGSTAFFE, who died on Jan. 22nd, was born in 1843. He was educated at Epsom College and subsequently at St. Thomas's Hospital, where, after holding the post of resident surgeon, he was appointed lecturer on anatomy in the medical school. In 1878 a sudden breakdown in health necessitated a period of rest abroad, and he was never able to return to active work. Mr. WILLIAM ILBERT HANCOCK, whose untimely and sudden death occurred on Jan. 26th, was born in 1873. He was assistant surgeon to the Royal London Ophthalmic Hospital. He possessed a charming personality and had been a fine athlete. Dr. HAROLD JAMES CROMPTON, one of the medical officers of the County Asylum, Prestwich, Manchester, died on Jan. 28th at the age of 37.

Sir CHARLES HAYES MARRIOTT, consulting surgeon to the Leicester Infirmary, died on Feb. 14th, aged 75. Mr. THOMAS KILNER CLARKE died at the age of 66. He was a leading consultant in Huddersfield and a wide area round it. Dr. JOHN W. TAYLOR, who died on Feb. 27th, was born in 1851. He was professor of gynæcology in the University of Birmingham. He was president of the British Gynæcological Society in 1904, and in 1898 delivered the Ingleby lectures on Extra-uterine Pregnancy. Dr. JAMES HENRY RICHARDSON, who died on Jan. 15th, was born in 1823. He was at one time professor of anatomy in the University of Toronto. He was also a member of the first staff of the Toronto General Hospital, which was founded in 1854, and was the last survivor of the original body. Dr. A. W. WHEATLY of South Kensington died on Feb. 13th at the age of 54. Dr. AUGUSTIN LE ROSSIGNOL died on Feb. 18th. He was born in 1842 and was one of the oldest practitioners in Jersey.

Professor EDWARD PERCEVAL WRIGHT, who died on March 2nd, aged 76, was professor of botany at Trinity College, Dublin, and in the advanced years of his life he combined enthusiasm for antiquarian research with unfaltering zeal for vegetable and animal biology. Dr. WALTER

BUTLER CHEADLE, who died on March 25th, was born in 1836. He was consulting physician to St. Mary's Hospital and to the Hospital for Sick Children, Great Ormond-street. His manner with children was particularly charming. In 1888 he delivered the classical Harveian lectures upon Rheumatism in Childhood. Dr. CHARLES ERNEST MACKENZIE KELLY died at Witney, Oxon, on March 28th. Dr. GEORGE CARPENTER, who died on March 27th, was born in 1859. He was physician to the Queen's Hospital for Children. Mr. FREDERIC VICTOR MILWARD died on March 31st, aged 39. He was assistant surgeon to the General Hospital, Birmingham, and surgeon to the Orthopædic Hospital and to the Children's Hospital in that city. Dr. STEWART LOCKIE, who died on April 18th, was born in 1836. He was consulting physician to Cumberland Infirmary. Mr. HERBERT NELSON CAPPE died on April 22nd, aged 44. He was one of the medical officers at Netherne. Dr. EDWARD CRESSWELL BABER died on May 14th, aged 59. He was well known in Brighton and Hove, where he was senior surgeon to the Brighton and Sussex Throat and Ear Hospital. Dr. HEINRICH CURSCHMANN, who died in May, was professor of medicine and director of the Medical Clinic in the University of Leipsic.

Professor ROBERT KOCH, one of a small group of pre-eminent men of science, also being members of the medical profession, died on May 27th, having been born in 1843. He was honorary professor of the Institute of Infectious Diseases, Berlin, and a Privy Councillor of the German Empire. In 1882 he took the medical world by storm, for he read a paper on the Etiology of Tuberculosis, wherein he stated that the disease was an infectious one and was caused by a bacillus, thus dominating the whole field of research in regard to tuberculous disease. The criteria or postulates which he enunciated as to the specificity of a micro-organism in relation to disease have become classical. Mr. RUSSELL STEELE, who died on May 18th, was consulting surgeon to the West Herts County Hospital. He was born in 1847, and practised at Hemel Hempstead. Mr. WILLIAM HOWELLS RIX, who died on May 24th, at the age of 74, was consulting surgeon to the Tunbridge Wells General Hospital. Mr. FREDERICK CHARLES HITCHINS, who died on May 8th, aged 38, was well known at St. Austell, Cornwall.

Sir FRANCIS SEYMOUR HADEN, who died on June 1st, was born in 1818. At the age of 33 he was appointed to be honorary surgeon to the then Government Department of Science and Art. His report in connexion with that department upon the progress of modern surgery brought him first into prominence. This report was issued for the International Exhibition of 1862, and gave an exhaustive history of operative surgery of the decade 1852–62. In 1867 he devoted himself to etching, and he was recognised by connoisseurs and artists to be a remarkable executant, and many of his compositions had a beauty which demands for its appreciation neither technical knowledge nor critical faculty. Mr. WILLIAM ROSE, who died in the early part of June, was born in 1847. He was emeritus professor of surgery in King's College and consulting surgeon to King's College Hospital. He was part author of one of the most popular text-books on surgery. His various contributions to surgical literature displayed him as a careful, skilful, practical surgeon. Dr. ELIZABETH BLACKWELL, who died on May 31st in her ninetieth year, was the first woman to obtain a place upon the English Medical Register. During the civil war in America she took a leading part in arranging for the nursing of the wounded. When a medical school was founded in New York she was invited to occupy a chair, and became professor of hygiene. On returning to England she joined the staff of the New Hospital for Women, and held the chair of gynæcology in the London School of Medicine for Women. Dr. W. H. SPENCER died on May 27th, aged 72. At one time he was consulting physician to the Bristol Royal Infirmary. Dr. ARTHUR JOHN SHARP, who died on June 6th, was born in 1867. He practised at Whitby for eight years. He subsequently moved to Nottingham, and also held the appointment of assistant medical officer to the Sheffield education authorities. Mr. FRANCIS EDWARD CANE died in May at the age of 55. He was divisional surgeon of the metropolitan police for the Edmonton district. Dr. SAMUEL BUCKLEY died on May 30th at the age of 64. He was consulting physician to the Manchester Northern Hospital for Diseases of Women and Children. He was also an ex-president of most of the medical societies of Manchester and of the North of England Obstetrical and Gynæcological Society. Dr. THOMAS EDWARD SMYTH, honorary surgeon to the Tavistock Cottage Hospital, died on June 28th at the age of 46. Mr. JAMES STARTIN died on June 2nd at the age of 58. He was senior surgeon and lecturer at the London Skin Hospital, Fitzroy-square. Dr. CLAUD MUIRHEAD, who died suddenly on June 22nd, was in his seventy-fifth year. He was consulting physician to the Royal Infirmary, Edinburgh, and one of the senior members of the medical profession in Edinburgh. HERBERT ROTHWELL GREENE PASHA, who died on June 4th, had a distinguished military and official career. He had acted as Director of the Egyptian Sanitary Department.

Dr. JOHN BART ROUS, who died in July, was born in 1878. After serving as house physician at St. Mary's Hospital, he forsook the paths of clinical medicine and became a member of the editorial staff of THE LANCET, who will long continue to deplore his untimely death. Our pages, during the past two years in particular, contain many examples of his wide range of general and scientific knowledge and of his literary charm and dexterity. Dr. GEORGE DANFORD THOMAS died on August 5th at the age of 63. As coroner for Central London he obtained the sincere regard of all who met him in the discharge of his important office. Numerous practitioners could testify to his excellent qualities in the examination of witnesses, the instruction of the jury, and to his unfailing courtesy to the medical profession, whose services he was most punctilious in requiting. Mr. J. E. PLATT, who died in the early part of August, was born in 1866. He was surgeon to the Royal Infirmary, Manchester, and lecturer on practical surgery at the Victoria University. He was regarded as one of the most brilliant students of the school and won many academic distinctions. As a surgeon, his work was characterised by extreme carefulness and attention to detail, qualities which, above all others, ensured the excellence of his results. Mr. WILLIAM BERRY, who died on July 29th, was born in 1874. He was medical officer of health of Wigan. He was surgeon to the infirmary in that town, and acquired a high reputation for his dexterity in abdominal surgery. Mr. FREDERICK WEATHERLY, who died on August 11th, aged 90, was a well-known practitioner at Portishead in Somerset. Dr. MARY ADAMSON MARSHALL died on August 8th at the age of 74. She was at one time senior physician to the New Hospital for Women, Marylebone.

Sir CONSTANTINE HOLMAN died on August 18th in his eighty-first year. He practised for many years at Reigate, and then came to London and became treasurer to Epsom College and to the Royal Medical Foundation attached to it. It is impossible to speak in too high terms of his services to these institutions and to the British Medical Association. Dr. JOSEPH NELSON, who died on August 31st in his seventieth year, was a well-known ophthalmic surgeon in

Belfast. He was one of the well-known ten of our countrymen associated with the movement for the liberation of Italy in 1860. Mr. JOHN LANGTON died on Sept. 11th, aged 70. He was consulting surgeon to St. Bartholomew's Hospital, to the City of London Lying-in Hospital, the Tottenham Hospital, the Friedenheim Home for the Dying, and the Mildmay Memorial Hospital. For nearly 40 years he was surgeon to the City of London Truss Society. For many years he was treasurer of the Medical Society, and subsequently president. He took a leading part in the formation and welfare of the Royal British Nurses' Association. Dr. LOMBE ATTHILL, who died suddenly at Strood Station, Rochester, on Sept. 14th at the age of 83, was senior Fellow and a past President of the Royal College of Physicians of Ireland and a past Master of the Rotunda Hospital. He was also President of the Royal Academy of Medicine in Ireland. He accomplished radical changes at the Rotunda Hospital, helping to bring the institution into its present state of excellence. Deputy-Surgeon-General JOHN LISTON PAUL, who died on August 25th, was born in 1827. In 1851 he entered the medical service of the Madras Army, and subsequently held the position of professor of surgery in the Madras Medical College. He was also surgeon to the Madras General Hospital. Dr. EMILY BLACKWELL, who died on Sept. 8th, was born in 1826. She received her professional education in the hospitals of New York, Edinburgh, Paris, and London. After the Civil War in America she became dean of the Women's Medical College in New York, and coöperated with her sister, Dr. ELIZABETH BLACKWELL, in founding and carrying on the New York Hospital for Women and Children.

Mr. CECIL HUNTINGTON LEAF died on Oct. 5th at the age of 46. He was surgeon to the Cancer Hospital, Brompton, and to the Gordon Hospital for Diseases of the Rectum. He wrote a valuable work on the Surgical Anatomy of the Lymphatic Glands. Dr. JOHN ANDERSON, who died on Oct. 10th, was born in 1840. Entering the Army Medical Service in 1864, he served for many years in India. On his return home he served in Edinburgh and at Camberley in connexion with the Royal Military College. He went back to India in a dignified and responsible capacity, for he was specially selected by the late Marquis of Ripon for his personal staff. He was subsequently made a Companion of the Indian Empire. Professor ERNST VON LEYDEN, who died in October, was born in 1832. He was formerly professor of clinical medicine and director of the First Medical Clinic of the University of Berlin. His earlier studies were devoted to diseases of the nervous system, but his work extended to many other departments of medicine. He took a prominent part in schemes for the prevention of tuberculosis, and was one of the presidents of the Central Committee on Tuberculosis. Mr. CHARLES HANLEN GAMBLE, who died in October, was born in 1825. He was consulting surgeon to the North Devon Infirmary. He practised in Barnstaple for about 60 years. Dr. DAVID HALKET STIRLING died on Oct. 14th. He served on the staff of the Royal Infirmary, Perth.

Dr. SIDNEY RINGER died on Oct. 14th at the age of 75. His professional career was closely associated with University College Hospital, at which institution he held every medical post, and where he was at the time of his death emeritus professor of medicine. In 1869 appeared his well-known "Handbook of Therapeutics," which in many directions revolutionised the sciences of which it treated. Dr. M. KRÖNLEIN, who died on Oct. 25th, was born in 1846. For 29 years he occupied the position of teacher of clinical surgery at the University of Zürich. Dr. LANCEREAUX, who died in November, was 80 years of age. He published a considerable number of works, including an "Atlas of Pathological Anatomy," an "Historical and Practical Treatise on Syphilis," and "A Treatise on Pathological Anatomy." One of his most important discoveries was the relationship between diabetes and disease of the pancreas. Dr. VIOLET ACKROYD TURKHUD died on Oct. 18th. She practised in Bombay and had made a thorough study of diseases of the tropics. Dr. JOSEPH FRANK PAYNE died on Nov. 16th in the seventieth year of his age. He was consulting physician to St. Thomas's Hospital. In 1874 he was Goulstonian lecturer at the Royal College of Physicians of London. This was the beginning of a very close connexion with the College, where he was Lumleian lecturer in 1891, Harveian orator in 1896, and Fitz Patrick lecturer in 1903 and 1904, and was appointed Harveian librarian in 1899. Senator ANGELO MOSSO died on Nov. 24th in Turin at the age of 64. He played many parts in the domain of biology, and amongst other investigations carried out some researches on the phenomena of respiration at altitudes above the snow-line. Dr. THOMAS FRANCIS SPITTAL CAVERHILL died on Nov. 4th. For many years he was medical officer of health of the county of Haddington. Dr. THOMAS NADAULD BRUSHFIELD died on Nov. 28th at the age of 81. He was for many years superintendent of the Surrey County Asylum at Brookwood and was a well-known antiquarian. Dr. EDWARD HENRY BRIEN died on Nov. 24th at the age of 52. He was a prominent practitioner at Birkenhead.

Mr. WILLIAM HENRY HORROCKS, who died this month at the age of 53, was senior honorary surgeon to the Bradford Royal Infirmary. He was chairman of the Bradford division of the British Medical Association. Among other deaths claimed by December may be mentioned those of the venerable Dr. JAMES E. POLLOCK, consulting physician to the Brompton Hospital for Consumption; of Mr. WILLIAM H. C. STAVELEY, a well-known London practitioner; and of Dr. H. HUCHARD, of Paris, a high authority on cardiac disease; and of Professor FRANZ KÖNIG, an ex-professor of surgery at the University of Berlin and the author of a well known treatise on surgery.

LITERARY INTELLIGENCE.—*Knowledge* for December contains an article by Dr. Reginald Morton on the X rays, which gives a lucid statement, tracing the evolution of our present knowledge concerning these rays, and rendering the general purpose and mode of their application understandable by the untechnical reader. The article is freely illustrated, but the illustrations of the tubes used, especially of the modern X ray tube, would have been more useful had an explanatory note been appended. As these figures are not specifically referred to in the text, their comprehension necessitates some practical acquaintance with the very subject of which it is the purpose of the article to expound the principia. In the same journal appears an article by Mr. John Gray on the measurement of perseveration and its value as an index of mental character. The same commendations for lucidity must be accorded to this article also. The phenomena and nature of the persistence of sensation after cessation of the stimulus are described, and the relation between such persistence and mental characteristics is explained in terms that must be clear to any intelligent reader. The apparatus devised by the author for measuring the persistence of sensation is figured and described. There is to be noted, however, an instance of what we consider a prevailing vice among scientific investigators. On the basis of the examination of 82 men and 26 women an attempt is made to determine whether there exists any coefficient of difference between the average perseveration of the two sexes, by comparing their respective means as deduced from the two before-mentioned groups. Any mean drawn from any number of observations is good only *pro tanto*, increasing or decreasing in value in direct ratio with the number of instances from which the mean is deduced. To compare two means, therefore, deduced respectively from three times as many members of one group as of the other is to ignore the law of the *écart* and to lay oneself open to unexpected failure. Yet this practice is very commonly followed.

Annotations.

"Ne quid nimis."

THE INFLUENCE OF TOBACCO ON DIGESTION.

A MEDICAL correspondent, who is also a discreet smoker, sends us the following interesting communication: "The act of smoking, comprising as it does the introduction into the mouth of pungent products of combustion, excites the flow of saliva, and as salivation is only the first of a series of digestive reflexes, once the process is started the apparatus as a whole follows suit. Pawlow has shown that the sight of food or the introduction of bitters into the mouth not only stimulates the salivary glands but causes the secretion of very active gastric juice. This is particularly noticeable in the subjects of hyperacidity, in whom smoking will determine heartburn and stomach cramp. It follows that smoking immediately after a meal, which is usually condemned and consistently practised, is not necessarily injurious; indeed, in hypopeptic subjects it may prove beneficial by virtue of its excito-secretory action. In acid dyspepsia, on the contrary, it is unquestionably injurious since its influence tends to aggravate any pre-existing acidity. Moreover, great acidity of the stomach contents may delay the evacuation of that organ *vié* the pylorus, and in sensitive subjects may cause a feeling of distressing distension. Such subjects ought, therefore, to postpone indulgence in tobacco until gastric digestion is well advanced, and if they suffer from the 'delayed' pain indicative of hyperacidity they should discontinue smoking altogether. Of course, the more copious the meal the less is the resulting inconvenience, because the excess of acid is neutralised by the excess of food. The desire for tobacco that is felt by many after a hearty meal is no doubt due to its stimulating influence on gastric secretion, and the comfort that follows indulgence is, in part at any rate, attributable to the extra fillip given to digestion. From this point of view the action of tobacco is preferable to that of a liqueur, which is a direct irritant. Smoking just before meals is to be deprecated, because the pungency of the pyroligneous products contained in tobacco-smoke renders the buccal mucosa insensitive to alimentary stimulation—in fact, their effect is to dull or abolish the olfacto-gustatory reflex, thus depriving us of what Pawlow calls 'appetite juice.' Moreover, by exhausting the salivary secretion, smoking before meals prevents the physiological action of the saliva on starchy foods." Our correspondent adds that smoking just before going to bed is often followed by insomnia, because the stomach contains a quantity of unneutralised juice, which irritates the mucosa and gives rise to a sensation of hunger. This distressing consequence may be averted by taking either some light food or a little bicarbonate of soda before retiring to rest in order to neutralise the secretion; but our suggestion here is that a habit, however pleasant, which leads to a distinct pathological condition requiring therapeutic treatment, ought to be censured by a medical man.

THE PUBLIC DRINKING CUP.

IN the United States of America public opinion is ripening for a campaign against the public drinking cup. These cups, attached by chains to the fountains in the streets, are sources of considerable peril, especially to children. The probabilities are that the majority of adults rinse out the metallic cups before drinking out of them, but children, whether using similar cups placed in their playgrounds or drinking from the street fountains, seldom take this precaution. Hot from a run or a game, they snatch up the cup and take a hasty drink without any preliminary rinsing out, and thus pathological conditions may be communicated from one to the other which, even in the intimacy of school life, had hitherto escaped dissemination. So obvious is this fact that several of the American States have passed laws abolishing such cups. In railway cars or at stations there are no cups; the railway servants have been supplied with cups to carry about with them, and every traveller in these States must make similar provison for his needs, inconvenient though it may be. To escape the difficulty some persons provide themselves with paper cups, which can be thrown away when they have been used, while there is also a device by which chained cups can still be employed, but without danger, called the "bubbling cup." Here a cup is attached to the fountain, but it has to be placed in such a position that the water perpetually flows into the cup and over the rim, so that all the time the cup is not being used it is being washed. The objection is the waste of water, but in many of the existing fountains the water runs perpetually, and the cups might only be attached to such fountains. The question of chained drinking cups in schools has been investigated, and it has been found that in many cases cups have not been cleaned for several months. In some cases there were dents in the bottom of the cup where a sufficiently large quantity of dirt was deposited for it to be possible to pick out and examine the accumulations. The microscope revealed that they consisted of mud, epithelium, and bacteria. With compulsory education it has become the bare duty of all concerned in school management to see that the children do not infect each other, and however trivial a precaution may seem it should be taken. To provide a system of common drinking cups in schools that shall be safe may not be easy, but to ensure the cups being regularly boiled ought to be no real trouble to anyone.

THE annual general meeting and conversazione of the Harveian Society will be held at the society's rooms in Tichborne-street on Thursday next, Jan. 5th. The retiring President, Dr. Montagu Handfield-Jones, will deliver an address on Science and Practice. A smoking concert will follow.

THE supplement to the thirty-ninth annual report of the Local Government Board, 1909–10, containing the report of the principal medical officer of the Board, has just been issued, and may be obtained at the price of 3*s*. 7*d*. from Messrs. Wyman and Sons, London; Messrs. Oliver and Boyd, Edinburgh; and Messrs. E. Ponsonby, Dublin.

THE Governor of Mauritius has reported to the Secretary of State for the Colonies, under date Dec. 23rd, 1910, that 27 cases of plague occurred during the week ended Dec. 22nd.

THE PUBLIC HEALTH IN NATAL.[1]

THE vital statistics of Natal for the year 1909 show a diminution in the European population as compared with the previous year; this was not due to any excessive mortality, but to the fact that there is a continual loss by emigration, which amounted in the year under review to 12,770. Dr. Ernest Hill, the health officer, gives no explanation for this, on the face of it, unsatisfactory feature in the polity of the colony, or—as it now is—province. He draws some consolation from the fact that the loss of population has fallen entirely on the towns (Durban and Maritzburg), the number of those engaged in utilising the resources of nature on the land having considerably increased. In 1904 a census was taken, and the population was 101,183; the estimated population, as at June 30th, 1909, was 98,934. It is pointed out that 30 days are allowed by law for the registration of death

[1] Report of the Health Officer for the Colony of Natal, 1909.

and that therefore deaths by violence, poison, &c., may occur, and burial take place, without any opportunity of inquiry. In some towns by-laws are in force requiring the production of a medical certificate before burial, and a draft Bill to secure proper registration of births, deaths, and marriages has been considered by the Government, but has not yet been brought before Parliament. It is to be hoped that, now the Union has been accomplished, there will be no further delay in passing this necessary enactment.

Another unsatisfactory feature is the steadily diminishing European birth-rate: in 1904 this stood at 31·1 per 1000; in 1909 it was 27·2. It is true that this is a higher figure than is registered in some other of our oversea dominions, but Dr. Hill points out that in Natal the sex distribution of the population is more favourable to a high birth-rate than it was six years ago. The death-rate for Europeans continues to decrease, and in 1909 was only 8·14 per 1000, the lowest on record. Maritzburg had a high rate of mortality (9·81) compared with Durban (7·44); this latter figure was also not only lower than the rate for the Colony generally, but lower even than the rate for rural populations (7·95).

Diarrhœal diseases were the most frequent cause of death, the ratio per 1000 inhabitants having been 0·75; this, however, was lower than in any year since 1904, when it was as high as 1·62. Tuberculosis of the lungs, meninges, &c., caused 0·6 death per 1000, and cancer 0·64. Small-pox is happily non-existent in Natal among Europeans, no death having occurred since 1904. Enteric fever also has materially diminished in recent years, the mortality having fallen to 0·19 in 1909.

The infantile mortality under one year shows a very welcome improvement, both as regards deaths from all causes (56·79 per 1000 births) and deaths from diarrhœal diseases (15·96), these ratios being lower than any previously recorded. Dr. Hill draws attention to the difference between Maritzburg and Durban, as shown by seven years' statistics; in the former town over 80 per cent. of the infantile diarrhœal deaths occurred in the five months of hot weather, and less than 4 per cent. in the four months of lowest incidence, whereas at Durban the deaths from this cause are distributed throughout the year. The minimum at Maritzburg occurs in midwinter; the maximum (in October) does not correspond to the period of maximum temperature (which comes in January), but to a time of moderate warmth, fair amount of rain, and great prevalence of flies. As the weather gets hotter there are more rain, less wind, and fewer flies. Durban, being on the coast, has a moist as well as warm climate nearly all the year round; there is no period of immunity from conditions favourable to diarrhœal disease. The diarrhœal death-rate ought to be lower in Maritzburg than in Durban, but on an average it has been 35 per cent. higher. Dr. Hill considers this to be a well-marked instance of the effects of good and bad sanitary administration respectively. Durban has had a water-carriage system of sewage removal for many years in most parts of the town, and is now completely served in that way; in Maritzburg pail closets only are in use, and these are emptied twice, or in some districts once only, in each week.

Enteric fever in Natal has diminished very markedly in recent years, the number of cases notified, which were 726 and 919 in 1902 and 1903, having fallen to 161 and 160 in 1908 and 1909. The deaths, which were 72 and 84 in 1902 and 1903, have dropped to 20 and 19 in 1908 and 1909. There was a small outbreak of ten cases at the Agricultural College, Cedara (apparently due to carrier infection); and at the South African Whaling Station, on the Bluff, there were five cases; otherwise there was nothing in the shape of an epidemic.

The diarrhœal death-rate for the general European population has improved greatly in recent years, the death-rate per 1000 having fallen steadily from 2·46 in 1902 to 0·75 in 1909; this has been largely due to improvement in sanitary conditions, resulting from better supervision and administration. The mortality from phthisis is lessening, though not rapidly; in 1905 very nearly half the deaths, as to which information was obtained, were of persons resident in the colony less than three years; in 1909 only two out of 31 who died had been less than three years in the colony. "This indicates that far fewer persons suffering from advanced consumption come to this country as a last hope; but, on the other hand, it also indicates a greater incidence of phthisis on the normal population, which will require very close attention in the future." Vaccination is in a very unsatisfactory condition: the "conscientious objector" flourishes.

In Natal there is a population of Indian immigrants slightly exceeding in numbers the Europeans, and amounting on June 30th, 1909, to 103,906. Their death-rate has been decreasing slowly, but in 1909 was 16·09 per 1000, or nearly double that of the Europeans. The chief causes of death have been pneumonia (2·12 per 1000), diarrhœal diseases (1·8), and tuberculosis of lungs (1·53). Ankylostomiasis caused 16 deaths, as compared with 29 in 1908; at the beginning of the year the number of indentured Indians discharging ova was found to be 60 per cent. of those examined, while in November and December it did not reach 15 per cent. Restriction was enforced on the allotment of new arrivals; microscopic examination of fæces was carried out, and remedies given where required. Owing to representations that the restrictions on landing were seriously interfering with the recruiting for labour the Board of Health advised that they might be relaxed, provided the Immigration Trust Board undertook that the infected persons should receive treatment, and the sanitary conditions of the Indian barracks be improved. The results were satisfactory.

The Native population is estimated at 996,445, of whom 767,336 live in Natal proper and 229,109 in Zululand. Tuberculosis and syphilis are prevalent. Leprosy exists to a limited extent; Dr. Hill estimates the total number of persons affected to be about 450, of whom 66 are segregated in a "location" at Amatikulu.

CENTRAL MIDWIVES BOARD.

THE report on the work of the Board for the year ending March 31st, 1910, states that the names on the Midwives Roll at that date amounted to 29,209, an increase for the year of 1928. Of the total, 8147 had passed the Board's examination and 9643 were admitted to the Roll in virtue of prior certification under Section 2 of the Midwives Act. The total number of trained midwives was therefore 17,790, as against 11,419 untrained, the percentages being 61 and 39. Owing to the incompleteness of the returns made by the local supervising authorities it was impossible to estimate with accuracy the respective proportions in the case of practising midwives. A large percentage of the trained women obtained their certificate without any intention of ever practising, many others had ceased to do so, and a considerable number practised in the colonies or in foreign countries. There was no doubt that at the present time the untrained practising midwives were largely in excess of the trained.

The Board's memorandum on the meaning of the words "personally delivering," occurring in Rule C, 1 (1), sent to all the recognised training schools in January, 1909, has had a good effect in securing more careful observance of the requirements of the rule. An instance having occurred in which a training school was found to have neglected to pay due attention to the terms of the Board's circular, the training school was in consequence removed from the list of institutions in which midwives may be trained. At a subsequent date, the Board being satisfied that the rule was being strictly complied with, the institution was restored to the list.

The penal procedure of the Board as laid down in Rule D had been under consideration during the year. The rule provides that "the secretary, or other person appointed by the Board for the purpose," shall conduct the case on the hearing by the Board of a charge of malpractice, negligence, or misconduct against a midwife in respect of which a local supervising authority has found a *primâ facie* case to be established. In some cases the local supervising authority has claimed to have the conduct of the case, and, as in the opinion of the Board this would introduce confusion into the proceedings, the following resolution was passed:—

Resolved, that local supervising authorities be not allowed a hearing in penal proceedings before the Board, except by special leave of the Board, which may be given when in the course of such proceedings charges are made against an authority, or its officers, to which an answer may be reasonably expected.

The local supervising authority of Hertfordshire was desirous

that the collection of evidence, the formulation of the charges to be met, and the conduct of the case at the hearing should be left entirely to the authority, and that the Board should act in the matter in a purely judicial capacity. On receipt of this suggestion the Board decided to communicate with the local supervising authorities of England and Wales, stating the proposals made, and inquiring whether the authorities were in favour of amending Rule D accordingly. The replies received showed that 21 authorities were in favour of the alteration of procedure, and 66 against it, while 5 favoured the establishment of a circuit system whereby provincial courts for groups of counties might be held at certain appointed centres.

The number of cases of ophthalmia neonatorum coming to the notice of the Board in the course of its penal administration made it apparent that strong efforts should be made to combat the ignorance and carelessness which so frequently lead to the total destruction of the infant's eyesight. The rules had accordingly been strengthened by substituting "must" for "should" in the rule dealing with the cleansing of the child's eyelids, and by placing on the midwife the obligation of advising medical help in case of a purulent discharge in a woman who is pregnant or in labour.

It is satisfactory to observe that the reports of the medical officers of health show in many cases a continued improvement in the old type of midwife still practising under their supervision, in respect of cleanliness, carefulness, and observance of the rules.

THE OUTBREAK OF CHOLERA IN MADEIRA.

WE have received from our special correspondent, since our previous communication from him,[1] two interesting accounts of the cholera at Madeira, and the story as told does not redound to the credit of the central authorities at Lisbon, although it shows that the way in which the epidemic was tackled by the local authorities has been, as far as their means lay, practical and efficacious, while proving great resolution to meet the difficulties of the situation. The English population, it may be added, has escaped the attack. It will be remembered that the last note from our special correspondent on the matter indicated that the original infection took place about the middle of October. The cases which then occurred were in the lowest strata of the population and escaped notice for some time, while the epidemic progressed slowly, so that in the first five or six weeks only some 60 cases occurred, with 20 deaths.

With regard to the origin of the epidemic and its spread during the past month, our special correspondent writes as follows:—"Cholera seems to have been introduced into Madeira by emigrants from a passing steamer, probably Russians or Italians, on their voyage to South America. These people, unless epidemic sickness is recognised on board, roam about the least-frequented parts of Funchal whilst their steamer is coaling, and exchange their clothing and whatever else is marketable for drink and local produce. On the present occasion some time elapsed before the disease was identified, cases having occurred far and wide before the authorities realised what was happening, but as soon as the true nature of the invasion was demonstrated nothing could exceed the energy displayed by His Excellency the Civil Governor and all serving with him in measures of disinfection, isolation, water-supply, and house-to-house inspection. The protection of the people and the restraint of the epidemic were enthusiastically undertaken. A lazaretto has been opened east of Funchal for the reception of patients, and isolation hospitals are established in outlying districts. The direction of the principal hospital has been entrusted to Dr. João Lomelino, who has gained experience at Lourenço Marques, and who, with the official Lisbon delegate, Dr. Carlos Monteiro, has rendered excellent service. The statistics issued early in December showed that 542 persons had been attacked, and that 183 of them had died—a death percentage of about 33. But we knew that it would be necessary to add to these numbers a great many unreported cases, and if the issue here was favourable the percentage of deaths would be reduced. By Dec. 12th the attack had been well got under in Funchal, and most of the cases since reported have come from squalid and distant settlements. The Government at Lisbon have sent out to us a distinguished bacteriologist who has worked zealously and efficiently, but they have otherwise done little in the present calamity to earn the gratitude of their fellow citizens of Funchal or create confidence in the authority of the new *régime* in Portugal."

On Dec. 23rd we received a letter from our special correspondent which had been delayed in transit and did not reach this office until we had gone to press last week. In this letter he complains of the difficulties of communication making it impossible for regular correspondence, save by cablegram, to be transmitted. He adds: "Five or six cases are reported daily in Funchal and its suburbs, where the disease is well under control and fast subsiding; but the villages on the south side still contribute on a larger scale. In these localities the authorities have been thwarted by the ignorance and impatience of the people, who resent all restrictions and precautions, and who attribute the immunity of their social superiors to some sinister influence exerted by the Government. About 900 people have been attacked, and the deaths have been 280. The epidemic is still limited to the lower strata of the population. We are practically isolated, and we are bewildered to think why the Cape outward-bound boats refuse to drop our weekly mail."

From these communications the magnitude of the disaster which has fallen upon Madeira can be estimated. The epidemic, which appears to be now coming under complete control, was a moderately severe one, the spread of the disease during the end of November being rapid, so that from 900 to 1000 persons have suffered in a population of under 150,000. No English person has been attacked, and the cases amongst the Portuguese have been absolutely confined to the least sanitary, poorest, and most ignorant sections of the population. We must all of us sympathise deeply with the island, particularly with those to whom a good season in Madeira is of the first importance. It would seem that the Central Government at Lisbon has hardly realised the responsibilities attaching to office.

[1] See THE LANCET, Dec. 10th, p. 1716.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7619 births and 4946 deaths were registered during the week ending Dec. 17th. The annual rate of mortality in these towns, which had been equal to 18·1 and 16·8 per 1000 in the two preceding weeks, further declined to 15·2 in the week under notice. During the first 11 weeks of the current quarter the death-rate in these towns averaged 14·8 per 1000. In London during the same period the death-rate, calculated on a probably over-estimated population, was equal to 15·5 per 1000. The annual death-rates in the 77 towns in the week under notice ranged from 5·7 in East Ham, 6·5 in Handsworth, 7·2 in Smethwick, and 7·4 in Hornsey, all being suburban districts, to 21·1 in Swansea, 21·2 in Newcastle-upon-Tyne, 21·3 in Warrington, 22·2 in Tynemouth, and 23·3 in Burnley. The 4946 deaths from all causes in the 77 towns in the week under notice showed a further decline of 499 from the high numbers in the two preceding weeks, and included 397 which were referred to the principal epidemic diseases, against 420, 416, and 332 in the three preceding weeks; of these 397 deaths, 169 resulted from measles, 61 from whooping-cough, 61 from diarrhœa, 52 from diphtheria, 28 from scarlet fever, and 26 from enteric fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns was equal to 1·2 per 1000, against 1·3 and 1·0 in the two previous weeks. No death from any of these epidemic diseases was registered in the week under notice in East Ham, Halifax, Stockport, Hornsey, St. Helens, Huddersfield, or in 10 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·7 in Devonport and in Tynemouth, 3·9 in Rotherham, and 4·2 in Grimsby. The fatal cases of measles in the 77 towns, which had been 231 and 143 in the two previous weeks, rose again to 169 in the week under notice; the highest annual rates from this disease in the week were 1·6 in Rotherham, 1·8 in Oldham, 2·1 in Grimsby, and 2·8 in Tynemouth. The 61 deaths from whooping-cough were within one of the

number in the previous week, and caused annual rates equal to 1·2 in Norwich, 1·3 in Hartlepool, and 2·4 in Rotherham. The deaths attributed to diarrhœa which had steadily declined in the 15 preceding weeks from 527 to 39, rose again in the week under notice to 61, and showed a proportional excess in Burnley, Devonport, and Rochdale. The 52 deaths referred to diphtheria exceeded by 16 the number in the previous week, and included 19 in London and its suburban districts, 5 in Liverpool, 3 in Manchester, and 2 both in Devonport and in Blackburn. The 28 fatal cases of scarlet fever were fewer by 2 than those in the previous week; 6 occurred in London and its suburban districts, 4 in Birmingham, 4 in Liverpool, and 2 both in Sheffield and in Swansea. The 26 deaths referred to enteric fever also showed a slight increase, and included 6 in London, and 2 each in Grimsby, Manchester, and Hull. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had declined in the five preceding weeks from 1832 to 1719, had further fallen to 1680 on Saturday, Dec. 17th; 156 new cases of this disease were admitted to these hospitals during the week, against 170 and 169 in the two previous weeks. The 1448 deaths from all causes in London in the week under notice included 355 which were referred to pneumonia and other diseases of the respiratory system, against 669 and 506 in the two preceding weeks; and were 26 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 41, or 0·8 per cent., of the deaths registered during the week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-upon-Tyne, Leicester, Portsmouth, Salford, and in 51 smaller towns; the 41 uncertified causes of death in the 77 towns in the week under notice included 6 in Liverpool, 5 in Birmingham and in Stoke-on-Trent, and 3 each in Manchester, Blackburn, Hull, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 850 births and 598 deaths were registered during the week ending Dec. 17th. The annual rate of mortality in these towns, which had been equal to 17·5 and 17·2 in the two preceding weeks, further declined to 16·5 in the week under notice. During the first 11 weeks of the current quarter the death-rate in these eight towns averaged 14·9 per 1000, and slightly exceeded the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns in the week under notice ranged from 11·3 and 14·0 in Greenock and Perth, to 17·2 in Glasgow and 17·8 in Dundee and in Paisley. The 598 deaths from all causes in the eight towns during the week showed a further decline of 24 from the number in the previous week, and included 50 which were referred to the principal epidemic diseases, against 55, 47, and 40 in the three preceding weeks; of these 50 deaths, 18 resulted from diphtheria, 13 from whooping-cough, 9 from diarrhœa, 7 from scarlet fever, 2 rom measles, and 1 from "fever," but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns in the week under notice was equal to 1·4 per 1000, and exceeded by 0·2 the rate from the same diseases in the 77 English towns. The deaths referred to diphtheria in the eight Scotch towns, which had been 11 and 13 in the two previous weeks, further rose to 18 during the week, of which 8 occurred in Edinburgh, 4 in Glasgow, and 2 each in Leith and Perth. The 13 fatal cases of whooping-cough also showed an increase of five upon the number in the previous week, and included 7 in Glasgow, 3 in Dundee, and 2 in Leith. Of the 9 deaths attributed to diarrhœa, corresponding with the number in the previous week, 3 were returned in Glasgow, and 2 both in Dundee and Aberdeen. The 7 fatal cases of scarlet fever exceeded those in the previous week by 3, and included 2 each in Glasgow, Edinburgh, and Paisley. The death referred to "fever" occurred in Glasgow and was certified as cerebro-spinal meningitis. The deaths referred to diseases of the respiratory system in the eight towns, which had been 157 and 151 in the two preceding weeks, further declined to 122 in the week under notice, and were 93 below the number in the corresponding week of last year. The causes of 19, or 3·2 per cent., of the deaths in the eight towns during the week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 552 births and 432 deaths were registered during the week ending Dec. 17th. The mean annual rate of mortality in these towns, which had been equal to 18·1 and 19·6 per 1000 in the two preceding weeks, was again 19·6 in the week under notice. During the first eleven weeks of the current quarter the annual death-rate in these Irish towns averaged 17·6 per 1000; the mean rate during the same period did not exceed 14·8 in the 77 largest English towns and 14·9 in the eight Scotch towns. The annual death-rate during the week was equal to 19·8 in Dublin, 17·7 in Belfast, 20·5 in Cork, 20·4 in Londonderry, 21·9 in Limerick, and 35·1 in Waterford; the mean annual death-rate for the week in the 16 smallest of these Irish towns was equal to 20·4 per 1000. The 432 deaths from all causes in the 22 town districts during the week corresponded with the number in the previous week, and included 23 which were referred to the principal epidemic diseases, against 36 and 33 in the two previous weeks; these 23 deaths were equal to an annual rate of 1·0 per 1000; in the 77 English towns the mean rate from the same diseases for the week under notice was equal to 1·2, and in the eight Scotch towns to 1·4 per 1000. The 23 deaths from these epidemic diseases in the Irish towns included 10 from measles, 5 from diarrhœa, 3 from scarlet fever, 2 both from whooping-cough and enteric fever, and 1 from diphtheria, but not one from small-pox. The 10 fatal cases of measles showed an increase of 5 upon those returned in the previous week, and included 6 in Lurgan and 3 in Belfast. Three of the 5 deaths from diarrhœa, and 2 of the 3 from scarlet fever occurred in Belfast. The 2 deaths referred to enteric fever were returned in Dublin and Galway. The 2 deaths from whooping-cough showed a decline of 13 from the number in the previous week; and the fatal case of diphtheria occurred in Dublin. The deaths in the 22 towns during the week included 130 which were referred to pneumonia and other diseases of the respiratory system, against numbers increasing from 80 to 116 in the four preceding weeks. The causes of 12, or 2·8 per cent., of the deaths registered in the Irish towns in the week under notice were not certified; in the 77 English towns the proportion of uncertified deaths did not exceed 0·8 per cent., but was equal to 3·2 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Bernard G. Goodwin resigns his commission (dated Dec. 21st, 1910).

Lieutenant-Colonel C. W. Johnson, on arrival from Gibraltar, has been posted to the Eastern Command. Lieutenant-Colonel C. Birt, from the London District, has taken over medical charge of the Royal Infirmary, Dublin. Lieutenant-Colonel G. G. Adams has been transferred from Hyderabad to Colaba. Lieutenant-Colonel F. W. Gordon-Hall has been granted leave from Jan. 17th to Feb. 10th with permission to travel in France. Major S. J. C. P. Perry and Major G. E. F. Stammers have embarked for a tour of service in India. Major J. F. Burke has been transferred from the Western to the Southern Command. Major H. V. Prynne has been appointed to the Eastern Command. Major A. H. Morris has been granted leave of absence from Dec. 27th to Feb. 24th. Major F. Wade-Brown, from Kilworth Camp, has taken up duty at Cork. Major A. W. N. Bowen has been transferred from Poona to Kirkee. Captain R. J. Cahill, Captain E. J. H. Luxmoore, Captain K. A. C. Doig, Captain G. A. Kempthorne, and Captain S. C. Bowle have arrived home from India. Captain P. Dwyer has been transferred to the home establishment from India, tour-expired. Captain H. Ensor, D.S O., who has been serving with the medical branch of the Egyptian Army since May, 1902, has received his Majesty's permission to wear the Order of the Osmanieh (Fourth Class) which was recently conferred by H.H. the Khedive in recognition of valuable

services. Captain A. T. Frost has been appointed Specialist in Dermatology and Venereal Diseases to the Dublin District. Captain T. S. Coates, from Haulbowline, has taken up duty at the Royal Arsenal, Woolwich. Captain S. Field has embarked for a tour of service in Jamaica. Captain T. C. Potter, pathologist to Queen Alexandra's Military Hospital at Grosvenor-road, has left for Jamaica to take up special duty under the Colonial Office. Captain Edward Gibson has taken up service with the Egyptian army. Captain J. M. H. Conway has been transferred from Dublin to Kilbride. Lieutenant S. S. Dykes has been granted leave of absence from Dec. 28th to Jan. 31st, with permission to travel in France and Switzerland. Lieutenant F. H. Somers-Gardner has been transferred from Cosham to Hilsea. Lieutenant H. V. Stanley, from Kilworth Camp, has joined at Dublin.

INDIAN MEDICAL SERVICE.

Brevet-Colonel J. Shearer, C.B., D.S.O., has arrived home from India. Lieutenant-Colonel A. O. Evans, on return from leave, has been appointed Civil Surgeon at Maymyo. Lieutenant-Colonel A. Buchanan has been appointed Civil Surgeon of Amraoti and to the Executive and Medical Charge of the Amraoti District Jail. Lieutenant-Colonel R. C. MacWatt, Bengal, has been granted one year's leave home from India. Lieutenant-Colonel H. B. Melville and Major C. Duer have been confirmed by the Government of India in their appointments as Joint Civil Surgeons at Simla. Major A. Leventon has taken over charge of the Dibrugarh Jail from Lieutenant-Colonel E. R. W. C. Carroll. Major F. A. Smith (Bombay Presidency) and Major R. Bryson (Madras Presidency) have arrived home on leave from India. Major J. Woolley has rejoined his former appointment as Superintendent of the Central Jail at Bhagalpur. Major P. C. Gabbett, professor of surgery at the General Hospital, Madras, has been granted two years' combined leave. Major W. Lethbridge has taken up duty as Agency Surgeon at Wano. Major E. G. R. Whitcombe has received an extension of his leave up to Jan. 5th. Captain A. S. M. Peebles has been appointed Specialist in Mental Science to the Northern Army. Captain A. E. Grisewood, assistant plague medical officer at Hoshiarpur, has been appointed District Plague Medical Officer, Hoshiarpur, in succession to Captain H. Watts, proceeding on leave. Captain A. C. MacGilchrist has taken over the duties of Civil Surgeon at Jessore. Captain H. C. Brown has been posted to the charge of the Brigade Laboratory at Jullundur. Captain E. J. C. Macdonald, district plague medical officer at Sialkot, has been posted to Jhelum, relieving Captain S. B. Mehta, transferred. Captain H. B. Drake has received an extension of his leave. Lieutenant K. S. Thakur has been appointed to the officiating medical charge of the 31st Punjabis. Lieutenant H. Semon has arrived home on leave. Lieutenant A. C. Munro has been appointed Specialist in Ophthalmology to the 7th (Meerut) Division.

TERRITORIAL FORCE.

Infantry.

5th (Prince of Wales's) Battalion, The Devonshire Regiment: Surgeon-Major Ernest P. A. Mariette resigns his commission (dated Dec. 21st, 1910).

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Dec. 16th. There were present: Dr. F. de Havilland Hall, in the chair; Dr. J. Pickett, Dr. M. G. Biggs, Dr. M. Greenwood, Dr. F. J. Allan, Dr. F. C. Martley, Mr. J. Brindley James, Dr. J. W. Hunt, Mr. F. S. Edwards, Mr. F. J. Colyer, Dr. W. Knowsley Sibley, Dr. F. S. Palmer, Dr. St. Clair B. Shadwell, and Dr. J. B. Ball. The records of the society show that the business is very successful. The number of sickness claims received during the autumn is less than usual, and the claims have been for the most part of very short duration, so that the total amount of sick pay disbursed is considerably under the amount expected and provided for by the rates of contribution. The funds are rapidly growing and now amount to over £240,000. Prospectuses and all further information on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

Correspondence.

"Audi alteram partem."

THE MOTOR FUNCTIONS OF THE STOMACH.

To the Editor of THE LANCET.

SIR,—Apart from powerful peristaltic waves there is no physiological division of the gastric cavity, and most certainly no middle sphincter such as Mr. Gray describes, and this I state on the experience of about 1500 observations conducted on something well over 500 cases, so that although I do not claim to be an authority yet such experience is surely sufficient to refute Mr. Gray's contention. To those who know the work involved in these cases, not only in the examinations themselves but also in following them up, it is obvious that a busy surgeon with a large private and hospital practice could not give the time necessary for more than a very limited number of examinations. I presume I am one of those "radiographers and others" to whom Mr. Gray refers. May I suggest that it is just "radiographers and others," whose business it is, who are most likely to know the interpretation of radiographic shadows which are notoriously deceptive to those who are not experienced in their interpretation.

"The interpretations of radiographers require criticism," certainly, but that criticism should be well-informed, fair-minded, and intelligent. For instance, "One cannot allow that Dr. Barclay's observations (on the rate at which food leaves the stomach) confirm Dr. Hertz's when they differ on so important a point as the position of the pylorus," which is hardly a fair method of throwing doubt on Dr. Hertz in any case. Moreover, it is not a fact that I disagree with Dr. Hertz, as Mr. Gray will see if he looks up the *British Medical Journal* for August 27th, where I stated that "the stomach is placed almost entirely to the left of the middle line, and it is tubular, roughly J-shaped. The pylorus is about half an inch above the lowest point, which is slightly above the level of the umbilicus, and half an inch *to the right of the middle line.*" And yet Mr. Gray states and re-states, and yet again sets it down that I place the pylorus to the *left* of the mid-line and endeavours to throw doubt not only on my own findings but also on those of Dr. Hertz and others by reiterating as a fact a statement that I have never made. He has read into the words of a paper written two years ago a meaning they never had for anyone, except himself, and has used them in a way that is very reminiscent of recent electioneering tactics. At that time one could not get so good a screen examination as nowadays, and I remember well debating whether I was sufficiently convinced of the position of the pylorus to put it down on paper as I did later on. I am convinced of the folly of regarding the stomach as a cast-iron vessel and attempting to give exact shapes and positions for its various parts. The normal shape is neither here nor there, for it is altered at once if the stomach loses even a little of its tone—i.e., the greater curvature elongates and allows the lowest part to drop a little, the pylorus remaining in the same position presumably. This entirely accounts for the discrepancies in the descriptions of the normal shape. Maybe, if I examined the stomachs of savage tribes instead of civilised town dwellers, I would find tonic action more perfect in every normal subject and would find the pylorus the lowest point instead of some part of the pyloric portion of the greater curvature. I doubt if Mr. Gray knows these elementary facts, or that Pfahler and Holzknecht described the ideal rather than the usual stomach as having the pylorus as the lowest point. I am certain that they also place the pylorus in the same place as do "recent radiographers and others"—i.e., just to the right of the middle line, and therefore agreeing with Dr. Hertz and others. I also am certainly one of those who maintain that there is no peristalsis in the cardiac end, as Mr. Gray will see even in that old paper of mine which he quotes. He asks: "Why should peristalsis affect only a small part of the tonically contracted tube?" I cannot tell him why—I simply state facts and attempt to explain them if I can, whereas Mr. Gray has apparently started off with the idea that the stomach is bilocular and has adduced cases to prove it from a limited experience.

On the practical bearing of Mr. Gray's contention there is little to be said. The stoma of a gastro-jejunostomy appears to act quite as efficiently when placed 4 inches from the pylorus as when it is placed nearer. I have examined many cases after this operation has been successful and have invariably found the stoma patent and acting perfectly, even though the stoma was not close to the pylorus. In the operative failures I have only come across one instance of vicious circle vomiting, and in that case the stoma was as near to the pylorus as 2½ inches. The other cases of operative failures were due to different causes, some of which are detailed in a paper on Gastric Radioscopy in the *Archives of the Roentgen Ray* for October, 1910.

It is entirely against my wish that I am dragged into this controversy on so intricate a subject, and without trespassing on the hospitality of your columns to an unwarrantable extent I cannot answer more than the main thesis of Mr. Gray's papers which teem with assertions that urgently call for criticism, if not for refutation.

I am, Sir, yours faithfully,

Manchester, Dec. 20th, 1910. A. E. BARCLAY.

To the Editor of THE LANCET.

SIR,—I am afraid that little good—other than amusement to some of the readers of THE LANCET—will result from the discussion on this subject.

Dr. Hertz's remarks at first were chiefly confined to the functions of a healthy stomach—it is dangerous to use the word normal—but now he draws more deeply from pathological phenomena. The fact that the stomach evacuates its contents through the pylorus at once or in the absence of hydrochloric acid in pathological cases is no proof that the same occurs in health. One might as well say that the stomach is of no use in the normal human economy because a man can live an apparently healthy life after the whole or greater part of the stomach has been removed.

Dr. Hertz's letter confirms my conviction that the ideas of what occurs in normal gastric digestion are in a tangled condition, at least, so far as the motor conditions of the stomach are concerned, and that the subject from a radiographer's point of view requires elucidation and agreement. The consensus of a small committee which had collectively investigated the subject would be valuable!

I am, Sir, yours faithfully,

Aberdeen, Dec. 24th, 1910. H. M. W. GRAY.

POLYDACTYLISM AND HEREDITY.

To the Editor of THE LANCET.

SIR,—Dr. Banks Raffle's letter in THE LANCET of Dec. 10th reminded me of a recent case here. The patient was affected by deformity of the hands, and one of her brothers showed a similar malformation; but so far as could be discovered no other members of the family manifested the same peculiarity. The patient was admitted as an ordinary case of puerperal mania and made a good recovery. She apparently had the full use of her hands, and busied herself with knitting, &c., and when at home performed all her duties in connexion with agricultural work and life without apparent difficulty. Although the patient was undoubtedly of a degenerative type, the heredity remains obscure.

Professor R. W. Reid of Aberdeen having examined the radiograms in this case reports that the middle phalanges of the index, middle and little fingers of the right hand are imperfectly formed and ankylosed to the distal ends of the proximal phalanges, but seem to articulate with the distal phalanges in the ordinary way. In the left hand the middle phalanges of the index and middle fingers are much shortened, but articulate normally at both distal and proximal ends. I am, Sir, yours faithfully,

Perth, Dec. 20th, 1910. A. R. URQUHART.

TREATMENT OF ULCERS OF THE LEG BY PASTE.

To the Editor of THE LANCET.

SIR,—I notice in your issue of Dec. 10th an abstract from the *University of Pennsylvania Hospital Bulletin* describing the treatment of ulcers of the leg by the use of Unna's paste. I do not know how long it may have been the practice in America, but your readers may be interested to know that this method of treatment has been in vogue at St. Bartholomew's Hospital for at least the last seven years with, on the whole, excellent results. In fact, it is perhaps the method of dealing with these troublesome ulcers most frequently used at that hospital. It is not used for the largest ulcers, because these discharge so much that the bandages, which are somewhat laborious to apply, would have to be frequently changed, but after a course of boroglyceride fomentations and antiseptic treatment most cases become reduced to manageable proportions, and are almost always cured by the use of the Unna's paste bandages. At first they are changed about twice a week, and subsequently at longer intervals up to a month. They are extremely comfortable, and give valuable support to the limb. Varicose veins, the usual cause of these ulcers, are, of course, also frequently associated with eczema of the leg, and this condition, too, can often be advantageously dealt with in the same way. The bandages are only contra-indicated if the discharge be too profuse. One point in applying them must particularly be emphasised, and that is that the limb must be kept raised for at least a quarter of an hour before application. If this be not done the bandage does not fit properly and soon becomes loose and uncomfortable, and has to be removed. I am, Sir, yours faithfully,

HALDIN. DAVIS, F.R.C.S. Eng.

Portman-street, W., Dec. 21st, 1910.

ERRORS OF REFRACTION IN THEIR REFLEX AND DISTANT MANIFESTATIONS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Dec. 17th, p. 1743, there appears a masterly and interesting lecture on "The Aftermath of Eye-strain," by Mr. Sydney Stephenson. This brought to my mind the case of a girl who was sent into St. George's-in-the-East Infirmary with a view to being sent to an idiot asylum, and who had been attending a special school for weak-minded children and found incapable of receiving instruction, whereas mentally the child was quite bright and was the victim of undetected compound hypermetropic astigmatism. The hypermetropia being greater than her power of accommodation, the child was not even "long-sighted"—she had no clear vision at all. The following are the brief notes of the case.

The patient was a girl aged 8 years. She was admitted to hospital on June 10th, 1899, as "mental hebetude." The mother informed me that the girl had been refused at school as she was an idiot. She was said to have had a "fit" a year ago. On June 10th she looked rather vacant and shy. On the 22nd the sister of the ward reported that the child played with the other children, and appeared to have a fair amount of intelligence. The child could count, but did not appear to have learnt to read. Was her sight defective? Yes. For she could neither see the position of the distant clock hands nor count small dots close to. Under homatropine it was found that with + 5 D. sph. and + 1 D. cyl. axis vert. she could, with each eye, count ⅛ inch dots at 20 feet. This state of refraction was confirmed by retinoscopy. She was supplied with spectacles and sent home, and *not* to an idiot asylum!

I am, Sir, yours faithfully,

Dec. 19th, 1910. MARCUS M. BOWLAN.

THE DETERMINING CAUSE OF CANCER IN MAN.

To the Editor of THE LANCET.

SIR,—May I beg space to point out some errors which have crept into the adaptation in black-and-white of my coloured schema—illustrating a new theory upon the above subject—and the letterpress accompanying it, in your issue of Dec. 24th, p. 1831? 1. On the schema as printed for "venous" read "arterial," and for "arterial" read "venous" (red and blue in the original). 2. For "pancreas" read "pancreatic duct" (green in the original). 3. The channel joining the liver with the gall-bladder and intestine (yellow in the original) are the "bile ducts," and not the "portal vein" as indicated by shading and description. 4. The areas indicated by decussating lines at the junction of the venous

and the arterial systems represent the "pulmonary" and the "systemic" capillaries," and not "lymphatics" as described.

I am, Sir, yours faithfully,

London, Dec. 24th, 1910. ROBT. HY. SCANES SPICER.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—In a volume just published by Messrs. John Murray and Sons, entitled "Induced Cell Division and Cancer," by Mr. H. C. Ross and Dr. J. W. Cropper, our names are quoted either in the preface or in the body of the work. We desire to say that, having had no opportunity of seeing the work previous to publication, either in manuscript or in proof, we think it only fair to disclaim any responsibility for the statements made and the conclusions arrived at by the authors. We are, Sir, yours faithfully,

R. J. HARVEY-GIBSON,
W. A. HERDMAN,
B. MOORE,
J. REYNOLDS GREEN,
C. S. SHERRINGTON.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Medical Units.

AT the headquarters, in Upper Chorlton-road, the annual parade took place recently for the prize presentations in connexion with the Royal Army Medical Corps (Territorial Force), East Lancashire Division. The great drill hall, gay with flags, was filled with a strong muster of men, officers, and guests. Colonel W. Coates, C.B., principal medical officer, East Lancashire Territorial Division, who deserves all praise for his devotion to the corps, presided. He was supported by Lieutenant-Colonel Sir Henry Mackinnon, K.C.B., C.V.O., general officer commanding in chief, Western Command; Colonel Lord Brackley and Lady Brackley; Colonel J. C. Culling, principal medical officer, Western Command; Colonel Damer Harrisson, R.A.M.C., T.F., Major Scott, R.A.M.C., and many others. In introducing Sir Henry Mackinnon, Colonel Coates said that the principal work of the year had been the formation of No. 18 Special Reserve Field Ambulance R.A.M.C., which was now ready for service at home and abroad. A division of the British Red Cross was now being formed in East Lancashire, and he thought that through their corps they could help the movement. There were hundreds of men who had passed through the ranks of the Royal Army Medical Corps who could go into these voluntary aid detachments without any further examination. Those wishing to join should communicate with headquarters. Those who joined would only undertake the obligation of possibly rendering aid to the wounded in the locality in which they lived. Colonel Bentley Mann gave an encouraging account of the present position of the East Lancashire Field Ambulance. Sir Henry Mackinnon said that he looked upon the medical units as an efficient and useful body of the Territorial Force. Their position was vastly improved since he last addressed them six years ago, and they had now got the medical service of the Territorial Force on a sound working basis.

National Minimum of Health.

Dr. James Niven's recent lecture to the Manchester Fabian Society was full of interest. He stated that, as shown by the Registrar-General's return, the death-rate of the country had been reduced by almost one-third since the quinquennial period of 1871–75. For those years the uncorrected death-rates were 22 per 1000. Thirty years later the death-rate was 16 per 1000, and in 1908 it was 14·7 per 1000. This was calculated to represent a value of over £12,000,000 a year. There are, however, obstacles to further progress. Boys and girls in our large towns are hurried off to work at the earliest possible moment, and their energies engrossed in acquiring technical skill and in earning wages. Little or no interest is taken in domestic matters. The girls know very little but what they have learned at school; hence they are very ignorant of how to make a comfortable home for their husbands, or how to rear healthy children. "They lose their babes, but pass through a painful apprenticeship in motherhood." Then come trade depressions, unemployment, crowding together of families, disease, and idleness, and probably one-tenth of the industrial population is subjected to deterioration, both physical and moral. Dr. Niven believed that ordinary punishment for neglect of children is useless and may be harmful. He would have power of detention, with enforced labour for the support of the wife and children. If girls are to be good mothers they must know how to take care of infants, and he remarked that excellent, though all too short, education is provided by the Manchester Education Authority for the senior girls in elementary schools. Dr. Niven desires a more extended and systematic course, to include cooking, cleaning, washing, sewing, mending, and so on; that the girl should be able to choose a house, know how to use it to the best advantage, and know also what goods to get, their prices, and how to combine them—in fact, all the things which make the difference between a well-kept and a badly-kept house. It will, however, be some time before Manchester girls become miniature Mrs. Beetons.

Typhoid Fever at Knutsford.

An inquest was held recently on a seven-year-old child in suggestive circumstances. Six weeks before the death the mother was taken to the hospital with typhoid fever. When she got back home on Nov. 2nd she found the child, whom she had left in the care of another woman, very ill, but she did not send for a medical man till the evening of the child's death. The medical evidence was that "death was caused by septic poisoning, due to the perforation of a typhoidal ulcer." The condition of the house was said to be such that it was perfectly impossible "for the child to get better." The coroner expressed surprise that the sanitary authorities did not visit the house after the mother's removal to the hospital. Evidently the Knutsford slums require looking after. From its position the town is not a very easy one to drain satisfactorily.

Dec. 27th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

The Training of Midwives.

AN effort is being made in Cardiganshire to raise funds voluntarily for the purpose of providing for the efficient training of midwives in the county. The proposal is not meeting altogether with the approval of some of the local sanitary authorities, who consider that the county council should provide the necessary funds so that each district will have to contribute its proper and fair proportion. The Merionethshire county council has for several years granted yearly three scholarships of £25 each for the training of midwives.

Cardiff Infirmary: Suggested Fees from Patients.

At a recent meeting of the board of management of the Cardiff Infirmary a recommendation was made by one of the committees that each in-patient should be called upon to pay 6*d.* a day and each out-patient 3*d.* weekly, unless their circumstances were such that they could not afford to make these payments. The proposal was approved by Lord Aberdare, who stated that this method of adding to the funds of the institution had been adopted elsewhere with success. The average weekly cost of each in-patient is £1 2*s.* 4*d.*, and it is estimated that the adoption of the proposal would add about £700 yearly to the income of the infirmary. The scheme did not meet with the approval of all the members of the board and no definite decision was come to on the matter.

An Isolation Hospital for Aberystwith.

The question of providing an isolation hospital for the town of Aberystwith has been under the consideration of the town council for a very long period and the need for such an institution has been felt upon many occasions. There appears to be some chance of this very necessary municipal equipment being provided, a plot of land two acres in extent having been offered to the council as a site. It is situated at the rear of the Aberystwith infirmary, and a suggestion has been made that it might be possible to administer the hospital from that institution. When the question was being discussed at a recent meeting of the town council one member

pointed out that the inhabitants of Aberystwith depended for their livelihood almost entirely upon the revenue derived from visitors and that one serious epidemic might absolutely ruin an industry upon which many were dependent.

Aberystwith Board of Guardians and Poor-law Medical Officer.

At a meeting of the Aberystwith board of guardians held recently a motion was carried by 24 votes to 5 giving notice to Mr. G. R. E. Bonsall to terminate his appointments as district medical officer, medical officer of the workhouse, and public vaccinator. The only definite reason which appears to have been given for the adoption of this course was a purely personal one between Mr. Bonsall and the member of the board who proposed the motion. Fortunately the consent of the Local Government Board is necessary before the medical officer's appointments can be terminated, though this is not the case with respect to the appointment of public vaccinator, and the central authority may be trusted to give an impartial consideration to the question which has been raised. The Poor-law inspector of the Local Government Board has borne testimony to the efficient and painstaking manner in which Mr. Bonsall has carried out his duties, and more than one member of the local authority pointed out that if the motion were passed no official would be safe from dismissal if he happened to have a private quarrel with one of the guardians.

Health of Merionethshire.

The estimated population of the county of Merioneth at the middle of 1909 was 48,800. The birth-rate during 1909 was 19·0 per 1000 of the inhabitants, and the death-rate from all causes 14·5 per 1000. Dr. Richard Jones, who for 17 years has prepared a statistical report for the county council, refers in his last report to the large number of infectious diseases in Merionethshire, a fact which he attributes to the absence of isolation hospital accommodation. He suggests that three combined districts should be formed for the purpose of providing these institutions. The Local Government Board has recently urged upon the council the desirability of making such accommodation, and suggests that a beginning should be made in the Dolgelly union. There does not seem to be any disposition on the part of the county council to give effect to these proposals.

Dec. 27th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Epidemic of Cholera.

ONE of the greatest difficulties confronting the sanitary authorities in their energetic attempts to stem the further progress of the scourge is the inability to discover the actual origins of infection. The epidemic is still spreading, and the peculiar feature about it is that a number of isolated cases appear here and there in quarters on the Bosphorus and the Golden Horn which are often very far apart and have no evident connexion with one another. These "cholera nests" seem to baffle all cleansing efforts, and new measures are being adopted, of which the following are the most important: Seven additional sanitary stations are to be constructed in various quarters, which will each have a medical man, two assistants, four porters, and all the necessary furniture, medicines, and instruments. At Ferikeuy, Stamboul, and Scutari three pavilions will be erected for the reception of patients. Sanitary inspectors will be attached to the municipality of Pera. The vigilant inspection of the shops, restaurants, coffee-houses, &c., has already begun. The managers of the theatres have received an injunction to have a special room equipped with necessary means for accommodating persons stricken with cholera during the theatrical performances. Every establishment of amusement will have a medical man in attendance. Strict, regular disinfection of these establishments is to be carried out under skilful supervision. Should a cholera case show itself in a theatre it will at once be closed. The Imperial Medical Society of Constantinople has issued a number of useful recommendations, such as the absolute necessity of increasing the staff of medical men in the municipal service. Attempts are being made to compel the boiling of drinking water in the hotels, schools, and pensions. Talaat Bey, the Minister of the Interior, has made the following interesting communication in Parliament: "As soon as the epidemic of cholera began to spread in Russia, the Superior Sanitary Council of Constantinople sent the necessary instructions to the medical authorities of the adjoining provinces and two lazarets were established at Trebizond. A special commission was sent to that town, as well as two torpedo-boats to survey the coast-line. Yet, in spite of these and other measures, it was impossible to prevent the epidemic spreading to Turkey. It made its first appearance in the province of Erzeroum and then in Trebizond." Talaat Bey has also stated that 50 medical men have been ordered to come to Constantinople to strengthen the sanitary service, and that 35 physicians who had proved incapable were dismissed. The hygienic service has been reinforced by 100 persons and the sum of £T1500 has been expended on disinfectants, but the general unsatisfactory sanitary and hygienic conditions of the metropolis render the task extremely difficult. The streets are dirty. The poverty of the population in many districts is very great, and their ignorance of the most elementary principles of cleanliness and hygiene is astounding. Mahmoud Shevket Pasha, the Minister of War, visits all the military schools, barracks, and hospitals every day to see that the hygienic instructions are strictly carried out.

Dec. 22nd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

A Medical Man Fined.

A RECENT action before the Ontario courts is of interest to members of the medical profession who patronise the automobile in their calling. The particulars of the case are as follows. Returning from a call, the medical man was descending a hill slowly in his motor car when he espied one of his patients, a farmer, unloading gravel from a wagon to which was attached a pair of spirited young horses. He did not blow his horn as the law requires, fearing that it would alarm the team, but stopped. He was approaching from the rear. The horses became unmanageable and ran away, the farmer being thrown upon his back in the wagon, his feet becoming entangled in the whiffletrees. The bumping of the wagon caused a rupture of the liver, and death occurred from internal hæmorrhage in little more than one hour. The jury found that the accident had arisen through the negligence of the defendant in not sounding his horn to apprise the farmer of his approach, and a fine was ordered.

Western Hospital, Montreal.

The authorities of the Western Hospital, Montreal, are appealing to the public for financial aid to the extent of $100,000. This money is needed for the erection and equipment of new buildings to accommodate the increasing number of patients who daily seek admission. In 1909 the hospital treated 1288 patients, of whom 609 were free patients, 323 paying a small sum, and 356 private cases. The average cost per patient per day was $1.44. The free patients cost the hospital $17,644, while the total public cash subscriptions only amounted to $9686.17.

Montreal Maternity Hospital.

It is stated that the past year has been one of the most satisfactory in the history of this institution. The total number of patients was 743, of whom 697 were discharged in good health, while 646 births took place in the hospital and only 2 maternal deaths occurred. The private patients numbered 150—an increase of 28 over the previous year. The finances were reported in a better condition than formerly, the endowment fund reaching $30,000, but as this only equalled about one-half the sum expended an urgent appeal is being made to the public for increased subscriptions. The needs of the hospital are an extension of the building and a new nurses' home. Reference was made to the great loss the hospital had recently sustained through the death of Dr. Arthur A. Browne.

Complimentary Banquet to Dr. Temple, Toronto.

On the evening of Nov. 26th Dr. J. Algernon Temple, Toronto, was entertained at a complimentary banquet in the York Club and a presentation was made to him by many of his medical friends in Toronto and others. The occasion

was the retirement of Dr. Temple from the chair of gynæcology in the Medical Department of the University of Toronto. For 40 years Dr. Temple was an active teacher, first as professor of obstetrics and gynæcology in Trinity Medical College, and afterwards when amalgamation took place with the University of Toronto as professor of gynæcology. Dr. John Taylor Fotheringham, Toronto, presided, and over 70 of Dr. Temple's friends and admirers in Toronto participated. Dr. Arthur Jukes Johnson presented an illuminated address, signed by all present, which expressed their admiration of Dr. Temple as teacher, friend, and physician. Dr. R. B. Nevitt, one of Dr. Temple's oldest students, presented him with a solid silver tea and coffee service. Dr. J. F. W. Ross proposed the health of Dr. Temple's old students, and Dr. Charles Sheard, late medical health officer of Toronto, responded. Dr. G. Stirling Ryerson proposed the health of lay friends and patients, to which Mr. E. B. Osler, M.P., and Mr. D. R. Wilike replied. Dr. Temple was very much moved by the many manifestations of friendship and goodwill and responded suitably.

Dec. 15th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Anterior Poliomyelitis in New York State.

IT is stated that the health officers of New York State have endorsed a proposal that the recently-formed State Legislature should be requested to make an appropriation to enable the State Health Department to undertake a thorough investigation of anterior poliomyelitis, with the view to take the steps necessary to stamp out the disease. The State Health Department has pointed out that the importance of such an investigation is obvious. Attention is drawn to the fact that during the past two or three years the disease has occurred in epidemic form over an ever widening territory and with an increasing number of cases. Surgeon-General Wyman, of the Public Health and Marine Hospital Service, has estimated that the records for the year 1910 will show upwards of 3000 cases, while 10 per cent. of those who have been attacked by the disease are left with more or less permanent paralysis.

The Work of the Guild of St. John in New York.

The Guild of St. John is a charitable organisation of New York city which concerns itself with the health of infants during the hot season of the year. The Guild supports a children's hospital on Staten Island and also provides trips and meals on its boats to infants and mothers in the summertime. According to statistics read recently by Professor W. H. Burr, President of the Guild, last summer was less severe on the small children and infants of New York than usual. The seaside hospital at New Dorp, Staten Island, received between June 1st and Sept. 15th 2400 mothers and children, 296 less than in 1909, and the number of days of hospital treatment was 20 per cent. less than in the previous year. Professor Burr recommended that the hospital should be used for convalescents during the months that it is not occupied by sick infants and mothers. In existing circumstances the hospital lies idle during eight months of the year, when it might be used for convalescents, maternity patients, and others.

The New York Milk Committee.

This committee was recently incorporated in New York State to improve the milk-supply of New York city and to educate the public in the proper use of milk for various purposes. Although the law provides for pasteurisation of certain grades of milk, some secret and ingenious process has been used to evade it. Milk submitted to this process will not sour, but it undergoes another sort of decomposition, "rots," as it has been described. This miserable substitute for genuine pasteurisation has confused the mind of the public; and so bitter have been the attacks on what was supposed to be an altogether fraudulent process that a philanthropist, who has been supplying the poor with thoroughly pasteurised milk at a halfpenny a glass to the extent of some 4,000,000 gallons annually, has withdrawn this benefaction.

The Holman Association for the Promotion of Rural Nursing, Hygiene, and Social Service.

This new society has been incorporated by a number of New Yorkers distinguished socially and is to be supervised by well-known practitioners. Its work is to be done chiefly among the mountaineers of North Carolina, Tennessee, and Kentucky. The plans call for the building of hospitals along the course of new railways, the employment of competent physicians and nurses, and the outfitting of social workers and lecturers on hygiene, who are to travel from place to place. These mountaineers present an interesting problem. They are probably the purest-blooded Anglo-Saxons in the United States, being descended from the early English settlers, who betook themselves to the mountains, where they have remained for some 300 years untouched by railways and their blood unmixed with any foreign stream. Physically they are fine-looking people, being tall, blonde, and broad-shouldered, while many of the younger women are goddess-like in their appearance and carriage. They are, however, astonishingly illiterate, superstitious, and suspicious, as well as lawless. Their ideas of medicine and hygiene are about those that their ancestors brought with them from the old country, and an authoritative manner and an ability to carry out mummery in a convincing way are about all the equipment at present demanded of any practitioner amongst them.

Dec. 18th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending Nov. 12th show 5359 deaths for all India. The Bombay Presidency reported 1024; Madras Presidency, 282; Bengal Presidency, 200; the United Provinces, 1022; the Punjab, 856; the Central Provinces, 734; Mysore State, 358; Hyderabad State, 158; Central India, 158; and Rajputana, 503.

Inoculation Against Plague in the Punjab.

Captain C. A. Gill, I.M.S., Chief Plague Medical Officer in the Punjab, has compiled a valuable memorandum that has just been officially issued by the Punjab Government on the subject of the great advantages of inoculation as a prophylactic measure against plague infection.[1] In this a striking instance of the protective value of inoculation is quoted, based on a report made by Lieutenant E. S. Baillie, Civil Surgeon of Muzaffargarh. A *hakim* (native "doctor") was engaged in treating plague cases in the town and its vicinity. He was shrewd enough at the early stages of the epidemic to get himself inoculated, with the result that although he was constantly in the midst of infection he remained in perfect health throughout the epidemic. Unfortunately, however, he failed to get any of his family inoculated, nor did he advise others to follow his good example. It thus came about that infection, probably in the form of infected fleas, attached itself to his clothing whilst visiting his patients. In this manner he conveyed the disease to his own house and shop in an uninfected quarter of the town, with the result that after a few days rats began to die, and after a further interval his wife contracted the disease and died from plague.

Insanitary Bread-making.

The conditions under which the bread consumed by Europeans in India is prepared by native bakers need some close attention from the sanitary authorities. Bakeries are often ill-ventilated and insanitary in many respects, and the natives employed at the work are extremely filthy in their personal habits and clothing, and are quite ignorant of the most elementary rules of hygiene. Tuberculosis is, unfortunately, too prevalent amongst the inhabitants of the bazaars, from which places the bakers obtain their assistants, and this danger to public health should not be lost sight of when a sanitary inspection of a bakery is made. The floors of bakehouses in India are generally of rammed earth, which material does not allow of proper cleaning; the roofs are constructed of *darma* matting with bamboos and tiles. There are no proper chimneys, and smoke, dust, and dirt are liable to contaminate the materials from which the bread is made.

Vaccination in Bombay.

Lieutenant-Colonel T. E. Dyson, I.M.S., Sanitary Commissioner, in his report on Vaccination in the Bombay Presidency for 1909–10, states that during the year 665,602 persons were primarily vaccinated and 48,885 revaccinated,

[1] See THE LANCET, Dec. 17th, p. 1789.

against 672,252 and 52,362 in the previous year, showing a decrease of 6650 in primary and 3477 in revaccination. Out of 665,602 persons primarily vaccinated 609,827, or 91·62 per cent., were successful; 6429 were unsuccessful; while in 49,661 cases the results could not be ascertained. The percentage of success excluding "unknown" was 98·96. Revaccination cases numbered 48,885, the percentage of success being 42·91. In 19,354 instances the result could not be ascertained, and in 8628 the operation failed. The sex percentages in primary vaccination were 51·69 males and 48·31 females. In revaccination the percentages were 78·94 males and 21·06 females, and in the total number of persons vaccinated 53·56 and 46·44. Of the total number of persons primarily vaccinated, 4478 were Christians, 505,877 Hindus, 112,408 Mahomedans, 1562 Parsis, and 41,277 persons of other castes. The age details are compiled for three periods—viz., under 1 year, between 1 and 6 years, and above 6 years. The number under each age period primarily vaccinated was 523,893, 121,197, and 20,512 respectively. The ratio of infantile protection afforded during the year was 73·43 per cent. The total expenditure on account of vaccination as compared with the preceding year was Rs.3,47,974 (£23,198 4*s.*), as against Rs.3,27,369, an increase of Rs.20,604.

The Medical Department of the Army.

All military medical officers below the rank of colonel have been directed to furnish to headquarters at the close of each year a short essay on the improvements they have noticed during the past twelve months in matters connected with the medical services. They are also required to make any suggestions for the improvement thereof in any particular branch. This is a step in the right direction, which might well be followed by the home authorities. It is to be hoped, however, that the "*suggestions*" will not be "committed" to the extensive vaults known to exist at army headquarters, Simla.

Nov. 26th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Lunacy in Victoria.

IN the annual report of the Inspector-General of the Insane for Victoria, Mr. Ernest Jones, it is stated that the authorities had been asked, "Were mental disorders becoming more prevalent during youth and adolescence?" The statistics at Kew were examined for a period of 27 years, and Mr. Jones thinks that the increase shown is more apparent than real. The total number of insane persons known to the department was 5200. The report states that the Lunacy Act requires amendment to permit the voluntary admission into certain State institutions on the application of the patient; to permit, under safeguards, the admission of voluntary applicants to private licensed houses; to legalise the certification of such patients in various directions either of discharge or incurability. Provision should also be made for legalising home treatment of certain cases of mental disorder. Mental hospitals should be provided apart from asylums. A whole-time pathologist was needed. The expenditure for the year was £163,116. The cost per patient averaged 12*s.* 10¼*d.* per week.

Increase of Rats.

Soon after his arrival in Melbourne Dr. B. Burnett Ham, chairman of the Board of Health, expressed the view that Melbourne's freedom from plague was due to the fact that the species of rat prevailing was the grey and not the black rat. The latter type has since shown signs of decided increase, and at one wharf where a few years ago black rats formed only 6 per cent. of all rats caught, the percentage has risen to 21, and has been as high as 46. Dr. Ham proposed to introduce a Bill making every occupant of premises responsible for rat destruction on those premises.

Government Appointments.

The Federal Government recently announced that two women doctors, Dr. Muriel Davies and Dr. J. Cohen, had been appointed to examine female government employees absent on sick leave. This announcement was immediately followed by a protest from the Women's Medical Association in Victoria. The members of this body, accompanied by several leading male practitioners, waited on the Federal Minister for Home Affairs and stated that while they had no personal objection to offer to the two ladies appointed, they were of opinion that no Government appointment should be made without calling for applications from any practitioner eligible to apply. Mr. King O'Malley protested his ignorance of the manner of appointment, but agreed that the deputation's request was reasonable and promised to look into the matter. It has since been found that 64 appointments of a similar kind have been made in Australia.

Federal Invalid Pensions.

The medical certificate entitling anyone to claim a Federal invalid pension must show that the person is suffering "from either one or other of the following disabilities or a disability of equal gravity":—

Accident.—The complete loss of a limb where such loss renders applicant permanently unable to work; the complete loss of vision.
Nervous system.—Locomotor ataxia (advanced), cerebro-spinal sclerosis, idiocy, epilepsy major with frequent fits, complete paralysis of a limb where such renders work impossible permanently, advanced diabetes, complete loss of vision in old age.
Respiratory system.—Advanced tuberculosis or miner's disease.
Circulatory system.—Heart disease with compensation failed; thoracic aneurysm.
Genito-urinary.—Advanced renal disease with dropsy.
Senility.—Advanced age (70) with degenerative arterial change; chronic articular rheumatism rendering person unable to work.
Unspecified.—Cancer or incurable wasting disease of any kind rendering patient unable to work.

Lady Talbot Milk Institute.

The Premier has promised to advance money for the support of this undertaking during the ensuing summer on condition that the management is put on a proper business footing.

Radium.

The Sydney Hospital has decided to buy £4000 worth of radium. Half this sum has been raised by public subscription and the Government has added the remainder. Dr. W. McMurray will proceed to Paris to purchase the radium, and on his return a special department will be established.

Weather Vagaries.

Melbourne has notoriously a capricious climate, but during the last few weeks the weather variations have been extraordinary. On Nov. 5th a record low reading for barometer was followed by a furious gale, with wintry temperatures. Three days later the shade temperature rose to 88°, followed next day by a drop to 60°. Cold weather followed, and a week later the thermometer rose in one day from an early morning reading of 46° to an afternoon shade reading of over 80°, with a record of 72° all night. Next day at noon the shade maximum was 90°; 20 minutes later the wind veered south, and in half an hour the shade temperature fell 22° F. In the evening the drop amounted to 30°. No visible effect in health is produced by these remarkable changes except on individual cases.

Personal.

Lady Dudley underwent a serious surgical operation on Nov. 19th at Federal Government House, Melbourne. Lady Dudley had been in bad health for some time and visited London last year for the purpose of undergoing an operation, which was performed by Mr. Hurry Fenwick. Her ladyship returned to Australia, and, although not strong, has been able to appear at various viceregal functions. Recently another surgical interference became imperative, and Dr. Douglas Shields operated, assisted by Dr. T. P. Dunhill and Dr. H. B. Devine. The operation is stated to have been successful, and at date of writing Lady Dudley's condition was satisfactory.

Nov. 25th.

Obituary.

SYDNEY JAMES RODERICK, M.B., C.M. EDIN.

WE much regret to record the death of Dr. Sydney Roderick, which took place on Dec. 18th at Vaux Hall, Llanelly, in his forty-sixth year.

Dr. Roderick was educated at Marlborough and at the University of Edinburgh, where a successful career was curtailed in order to permit of his carrying on at Llanelly the extensive practice of his uncle, the late Dr. Buckley. From the first he

showed a predilection for investigation, and readiness to bring the refinements of the laboratory to bear upon the problems of general practice, so that he soon was recognised as a valuable addition to the medical fraternity of the town and district. His medical *confrères* over a large area quickly learned to rely on him for assistance and information in X ray work and in the making of bacteriological investigations, blood examinations, and other laboratory procedure, and he willingly placed at their disposal his skill and knowledge. He was a thoroughly sound and good general practitioner and a skilful surgeon, but his bent was towards the scientific side of his profession, and he was one of the pioneers in South Wales in X ray development, radiotherapy, and opsonic work.

He was medical officer of health for the Llanelly area, medical inspector of schools, certifying factory surgeon, and medical officer to several works in the district, and from his public position no less than from his success in private practice was able to bring a powerful influence for good among his neighbours. He possessed those qualities of mind and character which, while they ensure respect, endear a man to all classes of the community, and he gained the affectionate esteem of everyone who knew him. Of a reserved disposition, he was not more in the public gaze than his posts necessitated—in fact, he studiously avoided publicity where possible. But his public knew him for a kind, sympathetic, and able man, always firm as a rock in opposition to wrong, and the display of sorrow at his death showed that his loss was deeply and widely felt.

Dr. Roderick left a widow and two children.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—A. De Luyck (Sections I. and II.), Brussels; J. Ellison (Sections I. and II.), Cambridge and St. George's Hospital; O. Marshall (Sections I. and II.), University College Hospital; G. Meyer (Section II.), Graz; and R. P. Wylde (Sections I. and II.), Manchester.

Medicine.—E. C. Banks (Section I.), Manchester; E. G. Brisco-Owen (Section II.), Cardiff and Royal Free Hospital; O. Marshall (Section I.), University College Hospital; T. F. O'Mahony (Section I.), London Hospital; and W. H. Parkinson (Sections I. and II.), Manchester.

Forensic Medicine.—A. De Luyck, Brussels; W. H. Parkinson, Manchester; and J. E. S. Sheppard Jones, St. Thomas's Hospital.

Midwifery.—E. C. Banks, Manchester; A. De Luyck, Brussels; and M. J. A. Des Ligneris, Berne.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—W. H. Parkinson and R. P. Wylde.

UNIVERSITY OF LEEDS.—At examinations held recently the following candidates were successful:—

DEGREES OF M.B. AND CH.B.

J. P. Brown, W. S. Hart, H. N. Ingham, J. P. Musson,* C. G. K. Sharpe, B. A. Slowcombe,* and G. V. Stockdale.*
* Second-class honours.

M.B., CH.B. SECOND EXAMINATION.

Anatomy and Physiology.—L. H. Butler, W. A. Drake, J. C. Gillies, H. R. Knowles, P. K. Messon, H. Sinson, H. L. Taylor, and C. Ward.

FINAL EXAMINATION, PART I.

Pathology, Forensic Medicine, and Public Health.—F. Wigglesworth and B. W. F. Wood.

DENTAL DIPLOMA.

Mr. Howden.

DIPLOMA IN PUBLIC HEALTH.

P. W. Ashmore, W. M. Hitchins, and J. H. Mason.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful:—

THIRD M.B. EXAMINATION.

Pharmacology, Therapeutics, and Hygiene—Walter Barnes, L. S. Daly, R. B. Gorst, C. L. Graham, Harold Harrison, G. B. Horrocks, T. P. Kilner, Frank Oppenheimer, W. J. A. Quine, and Harold Sheldon.

Pharmacology and Therapeutics.—C. T. G. Bird.

FIRST M.B. EXAMINATION.

Organic and Bio-Chemistry.—Gwendolen Birch-Jones and D. R. Garrett.

UNIVERSITY OF EDINBURGH.—At the Graduation Ceremonial on Dec. 21st the following degrees were conferred:—

Degree of Doctor of Medicine.—David Colvin Henry, Ronald Tydd Herdman, and George William Robert Skene.

Degree of Master of Surgery.—Mukhtar Ahmed Ansari, B.A. (*in absentiâ*). Thesis commended.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Edward Gordon Anderson (*in absentiâ*), Amédée Edwin Charles Beausoleil, Basil John Wilberforce Bennetts, Gilbert Burnet, Lawrence Dougal Callander, Thomas Forrest Craig, William Allison Dunn, Louis Thomas Eden, Arthur Charles England, James Erlank, Thomas Richard Evans, Alexander James Ewing, M.A., Annie Grange Fergus, Alexander Galletly, Frederick Peter Gibson, Matthew Edward Goode, Robert Govan, M.A., Max Greenberg, John Donald Gunn, B.A., Charles Cochrane Iles, Hannah Margaret Irving, B.Sc., Alexander Brown Jamieson, Charles Aloysius Keegan, Thomas Dymock Kennedy, William Douglas Kirkwood, Edward William Lawrence, Sea Foon Lee, Richard Charles Lowther, Duncan John M'Afee, Wilfrid Victor Macaskie, John Dugald M'Ewen, M.A., Marion Macintyre, Donald James M'Laren, Elizabeth Macleod, Arthur Murray Masters, Daniel Beresford Maunsell, Horace Macaulay Mills, Samuel Newman Mokand, Francis Laird Moore, Christoffel Cornelius Murray, Koka Ahobala Rao, Evan Williams Richards, William Robert Ridley, Thomas Robert Sandeman, Charlotte Dorothy Schaeffer, Subrata Chunder Sen, John Watt Senter, John Cormack Simpson, Austin Nimmo Smith, Norman Walter Stevens, John Stevenson, David Edmund Stodart, James Robert Stott, George Sutherland, Bernard Charles Tennent, Dirk Leonardus Theron, Pieter Hendrik du Toit, Chung Yik Wong (passed with Second-class honours), and Norman Campbell Young.

Diploma in Tropical Medicine and Hygiene.—William Henry Forsyth (Captain R.A.M.C.) (*in absentiâ*), Edward Charles Cecil Maunsell (Captain I.M.S.), and Allan Watson.

The Stark Scholarship in Clinical Medicine has been awarded to David Murray Lyon, M.B., Ch.B.

THE Queen has sent a Christmas donation of £10 to the Chelsea Hospital for Women.

THE MEDICAL TREATMENT OF SCHOOL CHILDREN.—At a recent meeting of the Marylebone division of the British Medical Association it was decided to convene a meeting of all the registered medical practitioners resident or practising in Marylebone, for the purpose of ascertaining their views upon the question of the medical treatment of school children found on inspection to be defective; and of considering what action, if any, should be taken to express those views. The meeting will be held on Monday, Jan. 9th, 1911, at the rooms of the Medical Society of London, Chandos-street, Cavendish-square, W., at 5 P.M.

ROYAL COLLEGE OF SURGEONS IN IRELAND AND "GRINDING."—The Council of the Royal College of Surgeons in Ireland has adopted very stringent regulations for the control of the "grinding" or private coaching which is a feature of Irish medical schools. No one is to be allowed to take private pupils in the school of the College who is not a Fellow of the College and approved by the Council on the recommendation of the dean. Moreover, every such "grinder" must pay an annual licence fee of five guineas, and certain capitation fees for his pupils according to scale. These capitation fees are in some cases greater than the fees usually charged to the pupils. The regulations practically crush "grinding" out of the school, and as students are not likely to rely entirely on official teaching, an exodus of students to other schools is not unlikely.

ROUX'S OPERATION FOR OVARIAN CYST.—Dr. Bastian publishes an interesting case of operation on a very large ovarian cyst in the October number of the *Revue Médicale de la Suisse Romande*. The patient, aged 79 (!), was suffering from acute dyspnœa producing deep cyanosis and from prolapse of the uterus and vagina owing to a very large ovarian tumour diagnosed as cyst. As mere puncture often proves inefficacious owing to the gelatinous nature of the contents of the cyst, Dr. Bastian decided to operate "à deux temps," imitating Dr. Roux in the treatment of a similar case. The first day Dr. Bastian made an incision of two inches in the median line under local anæsthesia with novocaine, sutured the cyst to the aperture and punctured it, leaving the contents to ooze out slowly. After 24 hours he broke down part of the remaining walls of the multilocular cyst, thus emptying the greater part of the fluid contents, and then after enlarging the external wound, also only under local anæsthesia, he opened the peritoneum, after suturing the aperture in the tumour, twisted the remnant of it, and pulled it out of the aperture and removed it. The ligature of the pedicle alone caused the patient some pain. Duration of operation 15 minutes. Normal temperature; good recovery.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, London.

On Acute Intestinal Toxæmia in Infants. An Experimental Investigation of the Etiology and Pathology of Epidemic or Summer Diarrhœa. By Ralph Vincent, M.D. An Address delivered before the Glasgow Obstetrical and Gynæcological Society on Nov. 23rd, 1910. Price 3*s*. 6*d*. net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CRIDLAND, A. B., F.R.C.S. Edin., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 25, with a view to his being employed in all ophthalmic cases which may arise in the Circuit.

DANIELS, D. W., F.R.C.S. Eng., M.D., B.S. Lond., has been appointed Surgical Registrar at the Prince of Wales's Hospital, N.

DREW, J. H., M.B., B.S. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Poole District of the county of Dorset.

EALES, W. H. FULFORD, B.Ch. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon to the Eye Hospital, Birmingham.

FISHER, R. W., M.B., B.S. R.U.I., has been appointed Medical Inspector of Police for the South and East Divisions of Belfast.

HARNETT, WILLIAM GEORGE, M.D. Dub., has been appointed Medical Superintendent of the Barnet Isolation Hospital.

JOHNSTON, T. ARNOLD, M.D. Edin., has been appointed Honorary Pathologist to the Leicester Infirmary.

MACDONALD, D. M., M.B., B.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Leven District of the county of Fife.

PARSONS, LEONARD, M.D. Lond., M.R.C.P. Lond., has been appointed Physician to Out-patients at the Birmingham and Midland Free Hospital for Sick Children.

REYNOLDS, LEWIS WILLIAM, M.R.C.S., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 37, more particularly to High Wycombe, Aylesbury, and Chesham County Courts.

RICHARDSON, J. N., M.D. Durh., M.R.C.S., has been appointed Medical Officer of Health of Ilkley.

SCOTT, H. HAROLD, M.D. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Bacteriologist and Fermentation Chemist to the Government of Jamaica.

WALLACE, D., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ullapool District of the county of Ross and Cromarty.

WYATT, W. L., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Hornsea District of the county of Yorks, East Riding.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARBADOS GENERAL HOSPITAL.—Senior Resident Surgeon. Salary £300 per annum and unfurnished quarters.

BEDFORD COUNTY HOSPITAL.—House Physician. Salary £80 per annum, with apartments, board, and laundry.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Assistant Physician. Also House Surgeon for six months. Salary at rate of £20 per annum, with board, residence, &c.

BOURNEMOUTH, ROYAL BOSCOMBE AND WEST HANTS HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, lodging, and washing.

BOURNEMOUTH, ROYAL VICTORIA HOSPITAL.—House Surgeon. Salary £100 per annum, with board, rooms, and laundry.

BRISTOL ROYAL INFIRMARY.—Two House Physicians and One House Surgeon. Salary £100 each per annum. Also One Obstetric and Ophthalmic House Surgeon, and One Throat, Nose, and Ear House Surgeon. Salary £75 each per annum. Also Casualty Officer for six montes. Salary £50 per annum. Apartments, board, and laundry are provided. Also Honorary Dental Anæsthetist. Also Honorary Medical Registrar. Also Dental House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—House Surgeon for six months. Also Second House Surgeon. Salary £80 per annum in each case, with board, residence, and laundry.

CANCER HOSPITAL, Fulham-road, London, S.W.—Surgical Registrar. Salary 50 guineas per annum. Also House Surgeon for six months. Salary £70 per annum.

CARDIGANSHIRE COUNTY COUNCIL.—Medical Officer. Salary £450 per annum.

CHELTENHAM GENERAL HOSPITAL.—Resident Surgeon. Salary £180 per annum, with rooms, coal, and gas.

EARLSWOOD ASYLUM, Redhill.—Junior Assistant Medical Officer, unmarried. Salary £130, with board, lodging, and washing.

GLASGOW MATERNITY AND WOMEN'S HOSPITAL.—Two Outdoor House Surgeons at the Hospital. Outdoor House Surgeon (female) to West-End Branch for three months. Also Two Visiting Gynæcologists, Two Assistant Gynæcologists, Two Supernumerary Assistant Gynæcologists, and House Surgeon, the appointment in last case being for six months.

GLOUCESTER, BARNWOOD HOUSE HOSPITAL FOR MENTAL DISEASES.—Second Assistant Medical Officer. Salary £160 per annum, with board, &c.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

HAMPSTEAD GENERAL HOSPITAL.—House Physician for eight months. Salary at rate of £70 per annum, with board and residence.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Assistant Casualty Medical Officer (and House Physician), unmarried, for six months. Salary £30, with board, residence, &c. Also House Surgeon, unmarried, for six months. Salary £30, with board, residence, &c.

HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.—Assistant House Surgeon (female). Salary £40 per annum, with board and laundry.

JERUSALEM, BRITISH OPHTHALMIC HOSPITAL.—Chief Surgeon. Salary £500.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—Honorary Assistant Surgeon.

LONDON HOSPITAL, WHITECHAPEL, E.—Medical Registrarship. Salary £100 per annum.

LONDON TEMPERANCE HOSPITAL.—Medical Registrar. Salary at rate of 40 guineas per annum.

MANCHESTER GENERAL HOSPITAL, Gartside-street.—Assistant Medical Officer for six months. Salary £100 per annum.

MANCHESTER VICTORIA MEMORIAL JEWISH HOSPITAL, Cheetham.—Resident Medical Officer (female) for six months. Salary at rate of £80 per annum.

NATIONAL HOSPITAL FOR THE RELIEF AND CURE OF THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.—Honorary Anæsthetist.

NEWCASTLE-UPON-TYNE, CITY HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Assistant. Salary £125 per annum, with board, lodging, &c.

NEWCASTLE-UPON-TYNE EDUCATION COMMITTEE.—Second Assistant Medical Officer. Salary £250 per annum.

NORTH SHIELDS, TYNEMOUTH VICTORIA JUBILEE INFIRMARY, Spring Gardens.—House Surgeon. Salary £100 per annum, with rooms, board, &c.

OCHILTREE PARISH COUNCIL, Ayrshire.—Medical Officer. Salary £25 per annum.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Surgeon.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Dental Surgeon. Salary £50 per annum.

READING, BERKSHIRE EDUCATION COMMITTEE.—Assistant Medical Inspector of Schools. Salary £300 per annum.

ROTHERHAM HOSPITAL.—Senior House Surgeon. Salary £110 per annum, with board, lodging, and washing.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Assistant Physician.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Surgeon.

RYDE, ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Resident House Surgeon. Salary £125 per annum.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Resident Medical Officer, unmarried. Salary £105 per annum, with residence and attendance.

ST. PAUL'S HOSPITAL FOR SKIN AND URINARY DISEASES, Red Lion-square, W.C.—Clinical Assistant.

SHEFFIELD ROYAL INFIRMARY.—Seventh Resident Medical Officer. Salary £60 per annum, with board and residence.

SOUTHAMPTON, FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

DUNN.—On Dec. 15th, at Beaufort East, Bath, to the wife of T. W. Newton Dunn, M.A., M.B., B.C., a son.

MARRIAGES.

HOLT—WADE.—On Dec. 15th, at St. Margaret's Church, Leytonstone, Arthur Knight Holt, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng., to Audrey Daisy, daughter of Mr. and Mrs. Charles Aubrey Wade, of Henfield, Sussex.

DEATHS.

COLLENS.—On Dec. 18th, in Vienna, of broncho-pneumonia, Edward Howard Collens, M.B., B.S. Lond., of Pen-y-Bryn, Hafod-road, Hereford, in his thirty-seventh year.

GREATHEAD.—On Oct. 26th, in North-East Rhodesia, John Baldwin Smithson Greathead, M.B., C.M. Edin.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

REFUSAL TO SUBMIT TO AN OPERATION.

A CASE under the Workmen's Compensation Act, 1906, of some medical interest, inasmuch as the question arising was whether the applicant had unreasonably or wrongly refused to submit to an operation, came before his honour Judge Scully, with Dr. J. C. Uhthoff as medical referee, at Haywards Heath county court on Dec. 15th. The applicant was a coachman who, in December of last year, met with an accident while chaff cutting, his ring finger on his left hand being crushed in the cogs of the machine. His employers, the respondents, paid him half wages up to September, but since then he had only been able to do light work and had not in any week earned more than 15*s*. Applicant had refused to have the finger amputated, and medical witnesses on his behalf stated there would be no general advantage in having the operation performed, as the removal of the damaged finger would not strengthen the hand or improve the other fingers or the grip of the hand. For the respondents, on the other hand, medical evidence was given that the removal of the injured finger would be a great improvement, and that while the man was under an anæsthetic the adhesions in the adjoining fingers could be also broken down and partly removed. The county court judge held that the refusal of the coachman to undergo an operation was not unreasonable, and awarded him 4*s*. a week compensation.

THE TREATMENT OF NETTLE-RASH.

To the Editor of THE LANCET.

SIR,—I shall be thankful if any of your readers will kindly give me a hint how to treat a form of nettle-rash which comes out, say, every third, fourth, or fifth day. Ichthyol has proved no good; aspirin, iodide of potassium, and colchicum checks the condition and makes the interval between the attacks longer. The patient is a female, aged 31, dark, small, wiry, and otherwise healthy.

I am, Sir, yours faithfully,

Dec. 24th, 1910. C. A.

ENCEINTE.

THE pronunciation of this polite word is a puzzle to many people, and its etymology we find is also in dispute. In Webster's dictionary (1891) its etymology is given as (F., fr. L. *in* not + *cinctus*, p.p. of *cingere*, to gird about). In the Encyclopædic Dictionary (Cassell, 1903) the etymology is given as Lat. *incinctus*, girt about: *incingo*, to gird about: *in* = in, around, and *cingo* = to gird. Robert Ainsworth, the Latin scholar, who published his dictionary in 1736, stated that *incinctus* meant (1) girded, environed, hemmed in; and (2) ungirded, loose. Here we have both sides at once. But for the word *Incingo* he gives only, "To gird, to gird about, to environ, to compass in," so how he came to give the second meaning for the participle remains obscure. Some students have thought the word *enceinte* to have a possible connexion with "*Inciens*," and Ainsworth quotes *Incientes oves*, ewes near their time of yeaning. To yean, or to ean, means in English to bring forth young as a sheep, or to lamb. *Ædcen* in Anglo-Saxon meant pregnant. Here, again, is a word very similar in appearance to *enceinte*. Dr. William Smith, LL.D., the well-known classical scholar and author of the dictionaries of Greek and Roman antiquities, gave in his Latin-English dictionary published in 1855 the derivation of the French *enceinte* and the Italian *incinta* (pregnant) as from the Latin *inciens*.

DRINK, MANIA, AND CRIME.

AT the Old Bailey Stanley Denniss, a carman, who was indicted for the murder of the youngest of his four children, a girl, aged 6 months, by strangling her, was proved to have been "very strange in his manner" on the morning of the crime, and after committing it to have remarked to a neighbour that she would "have a surprise in about five minutes." He then went into the street, where he met a constable, to whom he accused himself of the murder and gave himself up. He was out of work at the time, but his wife earned a little money as a charwoman, and he had been drinking heavily. The inquiries of a police inspector showed that other members of the prisoner's family had been confined as lunatics and that his father had committed suicide. The evidence of Dr. S. R. Dyer, medical officer at Brixton prison, who had reported on the case to the Director of Public Prosecutions, was to the effect that, taking into consideration the family history of the prisoner, he was of the opinion that alcohol affected him readily and had produced in him a condition of mental derangement at the time when he committed the murder, owing to which he did not know the nature and quality of his act or that it was wrong. Dr. Dyer was questioned by Mr. Justice Coleridge, who tried the case, as to the inference which might be drawn from the prisoner having gone immediately to a

policeman and given himself up, and replied that it was possible that it might have suddenly dawned upon the man that he had done wrong, so that at the time when he surrendered himself to the police he knew the nature and quality of the act he had committed. The jury accepted the view thus presented to them, and found that the prisoner was guilty of murder, but that he was insane when he committed it. The usual order for his detention as a criminal lunatic was made.

THE BONE CALLED "LUZ."

BY inadvertence we omitted to state in our annotation on this subject in our issue of Oct. 1st that the information was derived from an article by Mr. J. H. Garreson, contributed to the *New York Medical Journal* for July 23rd, 1910. In view of the fact that our annotation has been largely copied and commented upon by other journals we desire to place the credit for the facts in the proper quarter.

MOSSMAN FEVER.

UNDER the name of "Mossman fever" Mr. Oliver Smithson describes in the *Journal of Tropical Medicine and Hygiene* for December a peculiar fever common in some parts of North Queensland, occurring chiefly in the Mossman district, a few miles north of Port Douglas. The symptoms are sudden headache, and a feeling of general malaise, accompanied by shivering and a rise of temperature in a few hours to 102°, 103°, 105° F. The pulse-rate is increased, but not in proportion to the temperature. The tongue soon becomes coated with a moist white fur, and the breath is offensive. Vomiting and pains in the epigastrium occur, but are rare. Within a few days after the onset the posterior axillary glands become enlarged and painful to the touch. Occasionally the inguinal glands enlarge. The duration of the fever is from 10 to 14 days, the temperature dropping by crisis. In the few fatal cases the patient sinks into a typhoid state, grows very dull and lethargic, and has a sharp rise of temperature just before death. Blood examination is negative; occasionally the filaria sanguinis hominis has been found. The fever attacks only those engaged in cutting the sugar cane, the farmers and those working in the crushing mills being unaffected. The mosquito does not seem to be responsible for the disease, and apparently it is not infectious. Quinine, salicylate of soda, and salicylate of quinine are without effect on the temperature. The headache is best relieved by phenacetin, and simple saline mixtures seem to be most efficacious in rendering the patient comfortable.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
" 23rd (Paris).—First Congress of French Medical Journalists.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
" 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
" 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
" 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.
May 30th (The Hague).—International Congress on Opium.
May–October (Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
" (Turin).—International Congress of Pathology.
" (Genoa).—International Exhibition of Marine Hygiene.
Sept. 11th–15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).
" 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 18th–23rd (Sydney).—Australasian Medical Congress.
" 18th–24th (Turin).—Fourth National Congress of Hygiene.
" 24th–30th (Rome).—International Congress on Tuberculosis.
" 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Rome).—International Exhibition of Social Hygiene.
(Date uncertain) (Turin).—International Exhibition of Industry and Labour.

In 1912:—
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
" Visit of German Medical Men to America.
Nov. 22nd–29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—
(London).—Seventeenth International Congress of Medicine.
(Dresden (?)).—International Conference on Cancer.
August (Buffalo).—Fourth International Congress of School Hygiene.

In 1914:—
(Vienna).—Third International Congress for Professional Diseases.

In 1915:—
(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries G. F. Blacker, J. H. Targett): at 8 P.M.

Specimens:

Dr. Eardley Holland: Sarcoma of the Uterus with Hæmatometra.
Dr. S. Cameron: (1) Rupture of the Uterus through a Cæsarean Scar; (2) Twin Extra-uterine Pregnancy; (3) Osteomalacic Pelvis.
Dr. A. H. N. Lewers: Interstitial Gestation Sac of between Two and Four Months' Development, Removed Unruptured with the Body of the Uterus by Abdominal Hysterectomy.
Dr. Herbert Spencer: Suppurating Ovarian Cyst Perforated into Small Intestine and Omentum, successfully Removed with Affected Bowel, Omentum, and Appendix.

Paper:

Mr. Alban Doran: Subtotal Hysterectomy for Fibromyoma Uteri, Forty Additional Histories.

A DISCUSSION will be held on Wednesday and Thursday, Feb. 2nd and 3rd, to be opened by Dr. Amand Routh, on "The Indications for, and Technique of, Cæsarean Section, and its Alternatives in Women with Contracted Pelves, who have been Long in Labour and exposed to Septic Infection."

The following have signified their intention of taking part in the Discussion:—Dr. Malins, Dr. Briggs, Dr. Maxwell, Dr. Munro Kerr, Dr. Rayner, Dr. Eden, Dr. Herbert Spencer, Dr. Edge, and Dr. Russell.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—L. Hemington Pegler, W. H. Kelson), at 11, Chandos-street, W.: at 5 P.M.

Cases and Specimens.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchberne-street, Edgware-road, W.

THURSDAY.—8.15 P.M., Annual General Meeting and Conversazion Presidential Address:—Science and Practice.

RONTGEN SOCIETY, 20, Hanover-square, W.

THURSDAY.—8.15 P.M., Prof. Rutherford: The Radioactivity Thorium.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales' Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Dr. E. W. Goodall: The Rashes of Some of the Acute Infectious Diseases and the Rashes which Simulate them (illustrated by lantern slides).

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital.

FRIDAY.—8 P.M., Clinical Meeting. Cases will be shown.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (4th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (5th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor. 9 A.M., Major, 2 P.M.).

SATURDAY (7th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page for the current half year is published in this issue, which completes the second volume of the year 1910.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 will be ready shortly. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Aberdeen Royal Lunatic Asylum, information for students, 654
Aberdeen University Court and the Medical Ordinance, 261
Aberfeldy, hospital accommodation at, 1862
Abergavenny workhouse, 1380
Abortion, fatal attempts to self-induce, 322; Prevention and Treatment of (Dr. F. J. Taussig) (review), 1141
Abraham, Dr. J. J., the clinical aspects of "juvenile general paralysis," with an account of a case treated with "606," and observations on prophylaxis, 1877
Abraham, Dr. P. S., discussion on diet suitable in acute inflammatory diseases of skin, 558; on use of solid carbon dioxide in dermatology, 559; on dermatology, 391; some varieties of molluscum contagiosum, 811; specialists and specialism, an address, 1197
Abram, Dr. J. H., cases of long-continued fever of obscure causation, 1347
Abrams, heart reflex of, "kuatsu" and, 1501
Abrams, Dr. A., Spondylo-therapy: Spinal Concussion and the Application of other Methods to the Spine in the Treatment of Disease, 1910 (review), 1705
Abstracts and extracts in general and scientific literature, 583
Academy of Medicine, Paris, discussion on Professor Ehrlich's new remedy ("606") 1313
Accident cases, medical fees in, 506
Accidents, insurance against, question of inclusion of sunstroke in, 1384; in their Medico-legal Aspect by Leading Medical and Surgical Authorities, 1910 (review), 1423 (see also School accidents)
Acetanilide, death from, 915
Achard, Dr., method of differentiating living from dead leucocytes by staining with neutral red, 401
Achondroplasia, case of, 1344
Acidosis, pathogenesis, prophylaxis, and treatment of, 346; primary, 1356; recovery (Dr. S. Bontor), 1339
Acne, cases successfully treated by colon lavation (Dr. A. Mantle), 304; rosacea, treatment of, by tonogen, 1384
Aconite, case of poisoning by (Dr. W. Edgecomb), 1270
Acoustic nerve, right, angio-neurotic paralysis of, 1701
Acromegaly, case with hypertropied heart, pressor substances in urine, 552; partial, case of, 1833
Actinomycosis, 811; of neck and lower jaw, 1833
Adalia, plague at, 1311
Adami, Prof. J. G., discussion on avenues of infection in tuberculosis, 186; sisterhoods and tuberculosis, 188; the complete physicians, 1733; and Prof. A. G. Nicholls, Principles of Pathology (review), 381
Adams, Dr. C. E., obituary, 1387
Addenbrooke's Hospital, information for students, 608
Addis, Dr. S., pathogenesis of hereditary hæmophilia, 824
Addison, Mr. O. L., case of old healed tuberculous disease of knee-joint, 1696; case of sarcoma of femur, 1696
Adelaide Medical and Surgical Hospitals, Dublin, information for students, 665
Adenoid growths and tonsils, death after removal of, 1294
Adenoids in association with ear disease without nasal obstruction, 783; operation for, 782; removal of, statistics of, 23; and tonsils, hypertrophic, 782
Adenomatosis vaginæ, 1215
Adler doctor's car, 1851
Adnexa, vaginal route in treatment of lesions of, 1157
Adulteration of wine, a warning, 917
Adults, tuberculous meningitis in (Dr. W. B. Warrington), 1754
Advertisement, inadvertent in lay press, apology for, 1807; indecent, 207
Aeroplaning, dangers of (price of progress), 1226

Africa, British South, public health administration in, 897; Central, Universities Mission, need of medical man's assistance, 739; South, visit of Duke and Duchess of Connaught to, 1149; West, health in, 1183; medical staff of, promotions, 191; yellow fever in, 1552; South, British, conditions for British medical practice in, 697; South, medical organisation in, 1571
Agar plate cultures, method of staining deep colonies (Mr. E. Dodson), 310
Age and temperature, influence of, on potency of diphtheria antitoxin, 958
Agnathia and cyclops, case of, in lamb, 473
Agriculture, Department of, and the sanitary authority, 1862
Air embolism occurring during labour, 396; in heart, discovery of, after venous injection (Looking Back), 131; in lungs and blood, mechanism of gaseous interchange between, 828; purification and sterilisation of, Robertson, Rentoul, and Spencer apparatus for, 1087; and ventilation in modern warship, 817
Air liquid, in treatment of skin diseases, 1768
Air passages, lower, technique of direct examination of, 336
Airy Way, The (Mr. G. A. Dewar) (review), 1426
Albuminuria, intermittent, varieties of, 1348
Alcock, Lieut.-Col. A., Snakes (Tropical Medicine and Hygiene), 1910 (review), 1139
Alcohol, concentrated, action of 15 to 50 cubic centimetres of, on memory, 1040; effect of, on nervous system, 599; injection of, in treatment of laryngeal tuberculosis, 1710
Alcoholism in causation of insanity, 1063; and crime, social problem of, connexion between, 591; increase in Italy, 203; and offspring, 58
Ale, rustic, 1495
Alexander, Dr. D. M., and Newbolt, Mr. G. P., specimen of excised tumour of brain, 1768
Alexander, Dr. S. R., elected Mayor of Faversham, 1641
Alexander, Mr. William, complimentary banquet and presentation to, 199, 1517; resignation of, 577
Alexander's operation, value of, in treatment of retrodeviations of uterus, 1159
Alexandra, H.M. Queen, household medical appointments of, 1029
Alexandra Nurses' Home, Devonport, opening of, 1319
Alexandria, Aristotelian influence in, 1330; medicine in, 1330

Algeciras as health resort, 209
Algeria, public health in, 517; Flora of (Dr. A. S. Gubb) (review), 1838
Alienist physicians and neurologists of France and French-speaking countries, congress of, 590
Alimentary Hygiene, Second International Congress of, 1051
Alimentary system, section of, in medical museum of British Medical Association, 750
Alkalinity and cerebro-spinal fluid, 1
Allan, Dr. A. P., "Wigmore" nasal douche, 1563
Allbutt, Sir T. C., discussion on alcohol and nervous system, 400; on effect of digitalis on human heart, 487; FitzPatrick lectures on Greek medicine in Rome, delivered at the Royal College of Physicians of London, 1325, 1395; report of address to Edinburgh Royal Medical Society, 1247
Allen, Mr. H. E., Medical Register, 1103
Allen, Dr. J. F., bilharziosis and how to prevent it, 375, 576
Allen, Lieut.-Col. S. Glenn, discussion on naval recruits, 562
Allen's Commercial Organic Analyses (review), 1706
Alliott, Dr. A. J., obituary, 920
Alpine misadventure, 1522
Alvarenza prize of College of Physicians of Philadelphia, 1455
Ambulance service for London, 195; of Territorial service, 1374
Ambulatory treatment of fracture of leg, 1654
America, South, foreign medical practice in, 696
American Academy of Ophthalmology and Oto-Laryngology, anniversary lecture, 1113
American Dermatological Association, Transactions of, at the Thirty-third Annual Meeting held in Philadelphia, June, 1909 (review), 1772
American Electro-Therapeutic Association, convention of, 1144
American Federation of Sex Hygiene, 137
American Gynecological Society, Transactions of, vol. xxxiv., for Year 1909 (review), 382
American Medical Association, affairs of, 205; Sixty-sixth Annual Session, 67
American Practice of Surgery, 1909, vol. vi., vii. (review), 105
American surgeons, visit to England, 71
Ampoules, Sim's file for, 467
Amritsar, instruction in malarial fever prophylaxis at, 1316
Amyotrophy of acute and chronic rheumatism, 904
Anæmia, Addisonian (idiopathic pernicious), 1762; fatal case, Widal reaction obtained (Mr. P. Gully), 1827; pernicious, case terminating in acute diabetes (Dr. J. Parkinson), 543; intermission of, for 17 years, 1150; (soap), experiments on, 827; splenic, treatment by splenectomy (Dr. G. A. Sutherland and Mr. F. F. Burghard), 1819; cases treated by splenectomy, 1764
"Anæsthedone," 807
Anæsthesia in association with two cases of cerebral hæmorrhage, 1415; in Dental Surgery (Dr. T. D. Luke and Mr. J. S. Ross) (review), 1018; (inhalation) prevention and treatment of surgical shock during, 556; prolonged, maintained by ether and gas alternately, 1487; spinal, advantages of, 1159; personal experience of, 324; sixth nerve paralysis following, 578; surgical, hypnotism in relation to, 1764
Anæsthetics, administration of, 273; and V-shaped upper jaw, 59; committee of British Association, 844; Committee, General Medical Council, report, 1625; deaths under, question of our hospitals' responsibility in (leading article), 1022; (General) Bill, 1519; and legislation (leading article), 415; legislation on, 808; local, quinine as, 840; use of quinine and urea hydrochloride as, in ano-rectal surgery, 576; status lymphaticus in relation to use of, in surgery (Dr. D. W. Buxton), 365; and surgery in medical diseases (leading article), 742; use of, in surgery, status lymphaticus in its relations to, 587
Anæsthetics Act, proposed, and General Medical Council, 1722
Anaglyth, method of, for stereoscopic reproduction of medical photographs, 1366
Analgesia (see Spinal analgesia)

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Apricot Liqueur (Pricota), 34—Archena Water, 1495—Boulon Natural Mineral Water, 1143—Calmine Powder and Tablets, 1495—Caisa, 467—Cellasin, 895—Certified Complexion Soap, 1495—Crème de Menthe, 34—Diabetic foods, 467—Digestin, 895—Glashagen Mineral Water, 894—Hayden's Viburnum Compound, 467—Huxley's Proteid Food, 1142—Lacto-bacteria Tablets, 35—Lak-cit Milk Food, 35—Lin Aulagne, 1143—Medicated Throat Pastilles, 1495—Milk foods, 467—Olive Oil (B and G Brand), 467—Perpetuale, 467—Pom Powder Toilet Soap, 467—Preserved Mango Juice, 1142—Pure China teas and blends, 895—Rustic Ale, 1495—Salus Water, 35—Sim's File for Ampoules, 467—"Soloid Bile Salt" Agar-agar and Soloid Nutrients, 34—Sophol, 1143—Spirosal, 35—Stomike Coffee, 35—"Tabloid" Bismuth Gauze, 1142—Toni-Kola, 1495—Valier Cheese, 895—Vegetable charcoal preparations, 895—Vibrona, 1143—Virogen, 468—"Wellcome" Brand Tuberculin, 34

Anaphylactic animal, immunity in, 85; initial leucopenia in, after injection of unorganised antigens, 83
Anaphylactic shock, effect of deep-ether narcosis on, 84; reactive leucocytosis after, 89; state, nature of, 85
Anaphylaxia in hay fever, nettle-rash, and asthma (Dr. G. Billard), 1208
Anaphylaxis (leading article), 1224; relation of leucopenia to, 15
Anatomical material, methods of preservation, 475
Anatomical Society of Great Britain and Ireland, 1653
Anatomist, Emanuel Swedenborg as, 474
Anatomists, International Congress of, at Brussels, 551
Anatomy, ancient drawings of, from Tibet, 1149; Morbid, Handbook of, and Post-mortem Technique (Dr. C. R. Box) (review), 832; pathological, in epilepsy, 148; Second International Congress of, 764; Special Pathological, Text-book of, for Students and Practitioners (Lehrbuch der Speziellen Pathologischen Anatomie fur Studierende und Aerzte) (Dr. E. Kaufmann) (review), 1283
Ancient records of disease in Egypt, 416
Anderson, Mr. A. R., discussion on mortality of appendicitis, 1835
Anderson, Dr. H. M., tear of the inferior vena cava, with survival for nine hours, 976
Anderson, Dr. J., death of, 1152; obituary, 1251
Anderson, Dr. J. F., discussion on Poor-law reform and the medical profession, 407; influence of age and temperature on the potency of diphtheria antitoxin, 958
Anderson, Lieut.-Col. R., obituary, 1305
Anderson's College, Glasgow, appointment to professorship of midwifery, 201
Anderson's College Medical School, Glasgow, information for students, 649
Andrewes, Dr. F. W., Croonian lectures on the behaviour of the leucocytes in infection and immunity, delivered before the Royal College of Physicians of London, 8, 83, 153

Howard Mummery (President) on the reasons for susceptibility and natural immunity to dental caries, 562; papers by Mr. J. G. Turner and Mr. H. Baldwin, 818; Ophthalmology: Presidential address; Dr. G. A. Berry on the future of ocular therapeutics; other papers by Dr. J. W. H. Eyre, Mr. Arnold Lawson and Dr. Mackenzie Davidson, Dr. H. M. Traquair, and Mr. N. Bishop Harman and Dr. E. R. Morton, 482; Mr. W. T. Holmes Spicer and Mr. S. Mayou and others on the more chronic forms of anterior uveal inflammation; Dr. A. Hugh Thompson on the operative treatment of high myopia; other papers by Mr. Arthur H. Benson, Lt.-Col. L. J. Pisani, I.M.S., and Mr. A. F. MacCallan, 565; papers, &c., by Dr. J. S. Risien Russell, Mr. Bishop Harman (illustrated), and Maj. G. H. Fink, I.M.S., 819; Otology: Presidential address; Dr. W. Milligan and others on aural tuberculosis in children, 485; Dr. Robert Bárány and Mr. C. E. West and others on the diagnosis and treatment of infective labyrinthitis, 567;

papers by Dr. Jobson Horne, Mr. Yearsley, and Mr. Mark Hovell, 822; Pathology: Dr. F. W. Mott on the effect of alcohol on the nervous system; Dr. W. H. Willcox on the therapeutic use of alcohol vapour mixed with oxygen; Dr. Achard on a method of differentiating living from dead leucocytes by staining with neutral red, 399, 486; papers, &c., by Dr. T. Addis, Dr. E. E. Glynn, Dr. J. A. Braxton Hicks, Dr. G. W. Goodhart, Dr. R. A. Chisholm, Dr. C. Price-Jones, Mr. Gordon R. Ward, and Dr. Boycott, 824; Pharmacology and Therapeutics: Dr. O. F. Grünbaum on treatment with lactic acid organisms; Prof. R. Tanner Hewlett on certain cases of malade imaginaire; Dr. Alex. Bryce on the limitations of curdled milk therapy, 401; Prof. Wenckebach and others on the effect of digitalis upon the human heart, 486; papers by Dr. H. H. Dale, Prof. Hans Meyer, Prof. P. G. Unna, Dr. J. H. Fortescue-Brickdale, and others, 828; Physiology: Lieut.-Col. Melville, R.A.M.C., on the food requirements of man for sustenance and work, 403; Prof. E. A. Schäfer and others on the factors which make for an efficient circulation; Dr. Ivy McKenzie on healthy lungs and chest walls as factors in an efficient circulation, 487; papers by Dr. August Krogh, Dr. M. Ross Taylor, Dr. C. G. Douglas, and Dr. F. W. Edridge-Green, 828; Psychological Medicine and Neurology: Dr. Theophilus B. Hyslop (President) on the relationship of psychology to neurology; Dr. G. H. Savage on marriage and insanity; Dr. Leonard D. H. Baugh on paranoidal symptoms at the female climacteric, 404; Dr. J. S. Risien Russell and others on the treatment of tabes dorsalis, 489; papers by Dr. R. Bárány, Dr. D. G. Thomson, Dr. Bruce, Dr. Edwin L. Ash, and Dr. W. A. Jolly, 829; Radiology and Medical Electricity: papers &c., by Prof. Sir J. J. Thomson, F.R.S., Dr. H. Lewis Jones, Dr. Dominici and Dr. A. A. Warden, Mr. C. Thurstan Holland, Dr. E. Reginald Morton, and Dr. W. F. Somerville, 406; Dr. S. Jellinek on disorders and death following electric shock; other papers by Dr. L. Freund, Dr. Dawson Turner, and Dr. T. G. George, Dr. C. Bailey, Dr. Leonard A. Rowden, and Dr. J. B. Simpson, 490; Dr. G. Allpress Simmonds, Dr. W. S. Lazarus-Barlow, Mr. Alfred E. Barclay, Prof. Wenckebach, Dr. A. Howard Pirie, and Dr. Alfred C. Jordan, 831; State Medicine: Mrs. Sidney Webb and others on the relation of Poor-law reform to public health and the medical profession, 407; Dr. John Robertson on town planning in relation to public health; Dr. George Reid on the administrative control of ophthalmia neonatorum; Dr. James Niven on summer diarrhœa in relation to house flies, 568; Dr. James Kerr, Sir William Collins, M.P., Dr. Robert Milne, and Mr. F. E. Fremantle, 833; Surgery: Mr. Arbuthnot Lane and others on the operative treatment of simple fractures, 348; Prof. Theodore Kocher and others on the surgical treatment of exophthalmic goitre; Prof. G. W. Crile on certain factors which influence the immediate results of surgical operation, 471; Mr. Frederick D. Bird on conditions simulating cancer of the stomach; Mr. H. J. Paterson on the early diagnosis and treatment of gastric cancer; Prof. Alexis Thomson on the Pathological anatomy of cancer of the stomach; Mr. E. Deanesly on the excision of gastric ulcers; Mr. W. Ernest Miles on the radical abdomino-perineal operation for cancer of the rectum; other papers, &c., by Dr. Martel, Mr. C. J. Bond, Dr. C. MacLaurin, Dr. R. Kennedy, and Mr. P. J. Lockhart Mummery, 553; Tropical Medicine: Col. Sir David Bruce, F.R.S., and others on human trypanosomiasis; other papers by Lieut.-Col. J. R. Roberts, Mr. J. Cantlie, and Dr. Raghavendra Row, 408; Dr. Aldo Castellani, Prof. Fülleborn, Lieut.-Col. C. Birt, R.A.M.C., Dr. Phillips, Dr. Louis W. Sambon, Dr. Andrew Balfour, Maj. G. H. Fink, I.M.S., and Dr. F. C. Madden, 835; Sir Richard Havelock Charles, K.C.V.O., and others on special factors influencing the suitability of Europeans for life in the tropics, 492; Medical Association, annual exhibition, 493; annual meeting of, 244; seventy-eighth annual meeting in London, 551, 808; Presidential address (Mr. H. T. Butlin), 279, 321; address in medicine on recent progress in medical science, delivered at meeting in London (Dr. J. M. Bruce), 284; (leading article), 318; address in surgery on malignant disease, delivered at meeting of British Medical Association in London (Mr. H. G. Barling), 289; (leading article), 319; medical museum, 749

British Medical Association, Victorian branch, 437

British Medical Benevolent Fund, 186, 551, 756, 1427, 1839; Guild, 1658; support urgently needed, 1649

British Pharmaceutical Conference, forty-seventh annual meeting, 328

British Pharmacopœia, Synopsis of, 1898 (Compilation by Mr. H. W. Gadd) (review), 466

Budget, remarks on, 140

Building by-laws, defective, at Bolton, 199

Buildings for rinking, 778

Buist, Dr. R. C., discussion on falling birth-rate, 816

Bulgaria, cholera in, 1162; Bulgaria, Servia, and Roumania, cholera in, 1790

Bulkley, Dr. D., value of a very restricted diet (rice) in certain acute inflammatory diseases of the skin, 557

Bullet, revolver, complete destruction of cervical portion of spinal cord by, without involvement of sympathetic ocular fibres, 902; (shrapnel), removal of half of, which had remained embedded in leg of Arab for 11 years (Mr. J. B. Christopherson), 1010; wounds of spleen, 1452

Bullet wound, Brown-Séquard's paralysis due to, 1833

Bulletin of Entomological Research (review), 317

Bumm, Dr., leading principles of Cæsarean section, 1156

Bunch, Dr. J. L., vaccine therapy, 809

Burdett, Sir H., discussion on economic basis of hospital management, 351

Bureau d'Hygiène, 322

Burghard, Mr. F. F., System of Operative Surgery, by various authors (review), 30

Burghard, Mr. F. F., and Sutherland, Dr. G. A., the treatment of splenic anæmia by splenectomy, 1764, 1819

Burial, premature, fear of, 598

Burial grounds as affecting public health, 1321; (see also Cemetery)

Burma, Government of, report of chemical examiner and bacteriologist to, for 1909, 1656; lunatic asylums in, 1734; malaria in, 1735

Burns, Mr. J., deputation to, in favour of prohibition of use of unwashed flock for bedding, 120

Burns, X ray, treatment of, 811

Burrell, Mr. B. A., Elementary Course of Food Testing, 1910 (review), 1839

Burroughs, Mr. W. J., case of chronic constipation treated by faradism of the large intestine, 799

Burroughs, Wellcome, and Co., Messrs., prize conferred upon, by International Hygienic Exhibition, Buenos Aires, 1142; record number of distinctions at Brussels International Exhibition, 1054

Burton, Dr. H. L., registration of the medical student and the regulations of the General Medical Council, 1103

Bury, county borough of, report of medical officer of health, 1035

Burying ground at Forthill (Parliamentary question), 141

Bush nursing scheme, 436, 855, 1110, 1385

Bushby, Dr. T., development of multiple growths, 1346; Who is he? (illustrated), 1580

Bushire, plague in, 1310

Bust, life-sized, identity wanted, 1580

Butcher, Mr. W. D., discussion on vaccine therapy, 888

Butlin, Mr. H. T., carcinoma is a parasitic disease, 1794; discussion on legislation on anæsthetics, 809; presidential address at the Seventy-eighth Annual Meeting of the British Medical Association in London (evolution of the British Medical Association and its work), 279; (annotation), 321

Butter and Margarine Act, 73

Butyric Acid Test for Syphilis (Dr. H. Noguchi) (review), 1017

Buxton, Dr. D. W., dosimetric administration of chloroform, 388; the status lymphaticus in its relation to the use of anæsthetics in surgery (clinical lecture), 365

Buzzard, Dr. E. F., discussion on diagnostic values of ophthalmoplegia, 820; on treatment of tabes dorsalis, 490; thrombotic softening of the spinal cord as a cause of so-called "acute myelitis," 1723
Buzzard, Dr. T., foreign honorary membership conferred on, 1716
Bygott, Dr. A. H., discussion on Poor-law reform and the public health, 408; on sickness insurance, 480
Byles, Dr. Y. B., intravenous injection of salvarsan, or "606," 1795

C

Cabot, Dr. R. C., Physical Diagnosis, 1910 (review), 1424
Cadell, Dr. Grace, discussion on falling birth-rate, 816
Cæcum and ascending colon, volvulus of (Mr. R. J. Pye-Smith), 302
Cæcum, carcinoma of, removed after preliminary evacuation of fæcal abscess and ileo-sigmoidostomy, patient well year later (Mr. J. D. Malcolm), 1131
Cæsar, Mr. R. T., fatal accident to, 1312
Cæsarean section, 1156; different methods (classical, vaginal, and extra-peritoneal), 1156; for concealed accidental hæmorrhage, 1281; justification for, 1216; leading principles of, in Great Britain and Ireland; for conditions other than contracted pelvis, 1156; successfully performed twice in same patient, 1241; treatment of eclampsia gravidarum (Dr. F. J. McCann), 789; undertaken in presence of septic infection (Dr. R. D. Maxwell), 306; value and choice of the different methods of, 1156; modern methods for improvement of technic of, 1156; (see also Hebosteotomy v. Cæsarean section)
Caird, Prof. F. M., carcinoma of stomach, cases exhibited after operation, 1834; epithelioma of the tongue, 1419
Caithness, medical inspection of school children in, 1582
Calus, Dr. Joannes, quatercentenary of, 1162; anecdote of, 1845
Calcium, action of, 828
Calcium salts in epilepsy, 219
Calculus, renal, diagnosis of, 1693; by X rays, 1698; surgical treatment of, 517; value of screen examination in diagnosis of, 492; ureteral (vesical portion of ureter) specimen, 1557; impacted, removal from lower end of each ureter, 1834
Caldwell, Lieut.-Col. R., Military Hygiene, 1910 (review), 1619
Caledonian Medical Association, annual meeting, 1105
Calf muscles, treatment of rupture of, 100, 209
Calkins, Prof. G. N., Protozoology (review), 313
Calmette, Prof., discussion on influence of predisposition and heredity in tuberculosis, 1244
Calmine powder and tablets, 1495
Calsa, 467

Edgecombe, Dr. W., case of poisoning by aconite, 1270
Edinburgh, annual meeting of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, 117, 186; housing question at, 188; post-graduate students at, 702; University of, degrees in public health, 682; general council, 1450; graduation ceremonial, 339; information for students, 645; pass list, 348; rectorial address, 1380; voluntary health visitors of, 1729
Edinburgh Dental Hospital and School, information for students, 689
Edinburgh Medical Journal (review), 34, 317, 807, 953, 1494
Edinburgh Royal Infirmary, information for students, 643; new clinical medicine laboratory, 1247; nurses' prize-giving, 1173
Edinburgh Royal Medical Society, report of Sir C. Allbutt's address, 1247
Edinburgh Sanitary Society, 1518
Edinburgh School Board and the medical inspection of school children, 1518
Edinburgh School of Medicine for Women, information for students, 648
Edinburgh Students' Union, 1380
Edinburgh University Club of London, dinner, 206
Edmunds, Mr. W., discussion on school clinics for continuous treatment of defects of vision, 821
Edridge-Green, Dr. F. W., spectrometer for mapping out colour sensations, 829; visual sensations arising from excitation of the yellow spot, 829
Edsall, Prof. D. L., pathogenesis, prophylaxis, and treatment of acidosis, 346
Education, importance of, 1191; medical, absence of instruction of psycho-therapeutics in, 516; in United States, 137; in the United States of America (leading article), 242; present position of, 1120; suggested remedies, 1847; pharmaceutical, 1148; Physical Training Bill, 140, 272; primary, in Ireland, 767
Education Act, administration of, in relation to prevention and cure of diseases of throat and nose (Mr. T. J. Faulder), 97
Education of high myopes, 820
Education of students of medicine, 1306
Edward VII., H.M. King, Belfast memorial to, 980, 107; Bristol's memorial to, 1172; Indian hospital memorials to, 774; Gloucestershire memorial to, 1581; memorials to, 143; memorial to, in Belfast, 767; in Cornwall, 1581; in Devon, 1319; Welsh national memorial to, 1105
Edwards, Mr. E. H., honour conferred upon, 1716
Efficient ventilation, 1240
Egg, white of, as dressing, 275
Eggar, Dr. Max, and Fabre, Mme. Dr., effect of radium in case of multiple sclerosis, 1367
Egypt, ancient records of disease, 415; foreign medical practice in, 695; pellagra in, 1037; prevalence of certain diseases in (Capt. G. W. G. Hughes), 169; prisons in, sanitation of, 1513; Public Health Department of, 1298; typhoid fever in, 835
Ehrlich, Prof., new remedy of, for syphilis, 583; humour of, 598
Ehrlich-Hata's remedy "606," 913, 1108, 1649, 1656; (Fleet-Surg. W. E. Home), 1096; discussion on, at Paris Academy of Medicine, 1313; in internal diseases, 1864; intravenous injection of, 1795; practical experience with, 1768; in Russia, demand for, 1318; some failures with, 1867; in treatment of malaria, 1152; in treatment of recurrent fever in rats (Dr. J. McIntosh), 713; (leading article), 740; in treatment of syphilis (Dr. W. Wechselmann), 1295; treatment of syphilis, indications and contra-indications (Dr. E. Emery), 1543; treatment of syphilis with, theory and practice (Dr. J. McIntosh and Mr. P. Fildes), 1684; report of twenty cases (Mr. J. E. R. McDonagh), 711; (leading article), 740; Treatment of Syphilis by (Dr. J. Bresler) (review), 736; use of, 1797; in Prof. Treupel's clinic (Dr. J. G. Garson), 964; Wechselmann's apparatus for injection of, 1708
Eiken, Prof. Dr. von, technique of direct examination of the œsophagus and lower air passages, 396
Elbow-joint, fracture of, in children, 1802; syphilitic disease of, 1492
Electric currents, effect of, on micro-organisms, 1359; shock, disorders and death following, 490
Electrical currents, effects of, upon blood pressure, 552; treatment for relief of symptoms of prostatic obstruction (Dr. J. S. Bolton), 1009
Electrical Standardising, Testing, and Training Institution, information for students, 690
Electricity for treatment of uterine fibroids, 1241
Electro-coagulation, cancer of lower lip treated by, 1654
Electro-dynamic phenomena (Looking Back), 331
Electro-Therapeutical Section of Royal Society of Medicine, 1649
Elementary bodies, comparative therapeutic value of organic and inorganic compounds of, 828
Elementary Schools (Instruction in Hygiene) Bill, 273
Elephants' tusks, diseases of, in relation to billiard balls (Mr. J. Bland-Sutton), 1534
Elgin, Sanitary Congress at, 853
Elgood, Dr. C., practical analysis of human breast milk with regard to clinical conditions of mother and child, 812
Elliot-Blake, Mr. H., quackery, a proposal, 1024
Emaciation, great, accompanying hæmorrhagic diarrhœa, case of, 884
Embolism, air, occurring during labour, 396; of femoral artery, treatment by immediate massage, 962; pulmonary, and infarction of lung, following case of phlegmasia alba dolens, recovery (Mr. J. C. Curtis), 1841
Emery, Dr. E., preparation "606," treatment of syphilis by Ehrlich's method, indications and contra-indications, observations made in Germany, 1543
Emery, Dr. W. D'Este, pathology of syphilis, 1766; technique of a simplified form of the Wassermann reaction, 732; discussion on vaccine therapy, 888
Emigration statistics (Irish), 853
Emotion, effects of, 531; as factor in development of neuropathic and psychopathic symptoms (leading article), 572
Emphysema and chronic bronchitis as result of acute pneumonia (Dr. S. West), 1413
Emrys-Roberts, Dr. E., election to chair in University of Wales, 434
Enchondroma of phalanx following injury (Mr. T. H. Kellock), 1759; ossifying, 1769
Encephalitis, 1947
Endocarditis, nature of, 215
Endometritis, chronic results of curetting in, 1489; chronic symptoms and treatment of, 1489
Endothelial cells, phagocytosis of erythrocytes by (Dr. W. O. Meek), 1256
Endothelioma, inter-fascicular, of choroid, situated at optic disc, 171; of orbit, later history of case, 1278
England, South of, recent army manœuvres in, 1309, 1377; and Wales, pauperism in, 905
English, Mr. T. C., discussion on cystic disease of breast, 1417
English, difficult, 924; language in Chinese colleges, 343
English towns, health of, 53
Englishman's Year Book and Directory, 1911 (review), 1883
Ensor, Mr. H. C., obituary, 852
Enteric fever (see Typhoid fever)
Enterocele, partial, in obturator hernia (leading article), 1288
Enterolith causing intestinal obstruction, spontaneously cured by evacuation through umbilical fistulæ (Dr. D. M. Greig), 1613
Eosinophilia in relation to helminthic infection (Mr. G. D. White), 297
Epidemics in Italy the cause of outbreak of popular violence, 917
Epigastric vein, right superficial varix of, 1763
Epilepsy, age of onset, 149; borderline of (Dr. W. A. Turner), 151; confirmed, 219; convulsive element in, 147; exciting causes of, 149; heredity causation of, 1059; and hysteria, differences between, 151; idiopathic, 147; Morison lectures on (Dr. W. A. Turner), 147, 217; pathological anatomy in cases of, 148; predisposing causes of, 148; problem of, 147; psychical element in, 147; toxæmic, 150; treatment of, 217; treatment, dietetic and physical, 1583
Epileptic children, more frequent examination of, 50
Epileptoid phenomena, 151
Epiphyses, Separated, and Fractures (Mr. A. J. Walton) (review), 1017
Epiploon and bowels, adhesions of, to abdominal wall as consequence of laparotomies, 1158
Epistaxis, point in, 1595
Epithelioma of arm, 1767; squamous, of œsophagus, 1834; of tongue, 1419
Epsom College, annual general meeting, 49; founder's day, 422
Equanimity in medical and social problems (Æquanimitas, leading article), 1088
Ergot of rye, 52; active principles of, 828; effect of, on patellar reflex, 1580
Errata, 1050, 1595
Errors of refraction in their reflex and distant manifestations, 1940
Erythrocytes, phagocytosis of, by endothelial cells (Mr. W. O. Meek), 1266
Esliner, Prof. A. A., treatment of aortic aneurysm by the introduction of wire and the passage of a galvanic current, 1637
Esophoria not caused by refractive errors, preliminary observations on (Mr. R. A. Morell), 1274
Esperanto, travellers' manual of conversation (J. C. O'Connor) (review), 34
Ether, administration of, acute œdema of larynx due to, 44; open system of, 555; first operation under, in Europe, 1242, 1447; and gas alternately, prolonged anæsthesia maintained by, 1487; and oil, hypodermic injection of mixture of, 1731; narcosis, deep, effect on anaphylactic shock and leucopenia, 84
Ethics, medical, 1516, 1818; professional, instruction in, discussed at General Medical Council, 1625
Etiquette, medical, 1516
Ethnology in West Australia, 1385
Eugenics, 1190; main questions in, 764; and national degeneracy, 1064, 1553
Eunochoid skulls, 389

Europe, evolution of racial types of, and its bearing on racial factor in disease, 552
Europeans, plague among, 1516; special factors influencing suitability of, for life in tropics, 492
Evans, Mr. A., and Hick, Dr. P., epithelioma of arm, 1767
Evans, Mr. E. R., and others, case of multiple myeloma, with some observations on the nature of the "Bence Jones" protein found in the urine, 1403
Evans, Mr. W., treatment of hirsuties, 811
Eve, Dr. F. C., intense Pirquet's reaction with ulceration cured by horse serum, 60
Evelina Hospital for Sick Children, information for students, 640
Evidence, scientific, in the Crippen case (leading article), 1566
Evolution of the British Medical Association and its work, presidential address given at the seventy-eighth meeting of the British Medical Association in London (Mr. H. T. Butlin), 279, 321
Evolution, Faith of an Evolutionist (Dr. T. A. Palm) (review), 1561; and Heredity Phases of (Dr. P. B. Hart), (review), 1617; of racial types of Europe and its bearing on racial factors in disease, 552; Super-organic, Nature and the Social Problem (Dr. E. Lluria, review), 892
Ewart, Dr. W., discussion on treatment of chronic constipation, 470; dorsal percussion of the thorax and of the stomach, 101; pre-tuberculosis and pre-pulmonary tuberculosis and their diagnosis in relation to school inspection, 308; value of percussion of the vertebra in diagnosis, 470
Ewart, Dr. C. T., eugenics and degeneracy, 1553
Examination, Medical, of Schools and Scholars (Dr. T. N. Kelynack, review), 1138
Examinations (life assurance), fee for, 962; medical, under Workmen's Compensation Act (leading article), 899
Exeter City Asylum, 259; District Nursing Association, 1171
Exhibitions: Annual exhibition of the British Medical Association, 493; Antwerp Scientific Exhibition, 843; Brussels Universal Exhibition, 589, 849, 978; International Exhibition of School Hygiene, 854; International Hygienic Exhibition, Buenos Aires, 1910, 1142; Japan-British Exhibition, 848; London Medical Exhibition, 1093; Prevention of Tuberculosis Exhibition at Edinburgh, 117; Tuberculous Exhibition, Liverpool, 133
Exostoses, multiple cartilaginous, 1344, 1552
Experiments on living animals, 273
Extra-dural abscess tracking through jugular foramen into neck, 1551
Extra-ocular manifestations of anterior uveal inflammation, 565
Extra Pharmacopœia of Martindale and Westcott (review), 383
Extremities, conservative surgery of, 1295; lower, shock in injuries of, use of stovaine in treatment of (Mr. G. Thom), 1014
Eye, action of atoxyl on, 1149; diagnosis chart, 362; diseases of, sero-therapeutic treatment in, 1232; retinal vessels of, arterio-sclerotic changes in, 1833; right, ophthalmoplegia externa of, 889; and ear, affections of, treatment of school children suffering from, 506; Ear, and Throat Infirmary of Edinburgh, information for students, 648; Hospital, new, at Liverpool (St. Paul's), 338; Infirmary, Bristol, 1311; remarkable case of injury to, 1242; work, use of carbon dioxide snow in, 484
Eyestrain and headache, 533; sequels (aftermath) of (Mr. L. Stephenson), 1743
Eyes, atrophy of, and oculo-motor palsy due to intracranial new growth, 171
Eyesight, defective, of children, discussion on medical treatment of, by Liverpool workhouse committee, 979
Eyre, Dr. J. W. H., bacterial products in ocular therapeutics, 484
Eyre, Dr. John, use of filthy flock for bedding, 258

F

Fabre, Madame, action of radium on toxins, 1366; discussion on radium treatment of angioma, 1367
Fabre, Mme. Dr., and Egger, Dr. Max, effect of radium in case of multiple sclerosis, 1367
Face, sun-burnt, 574
Face and neck, right, congenital port wine stain of, 1833
Face-screen, new, 466
Factories, wool-combing, dust in (Parliamentary question), 1659
Faculty of Medicine, Paris, appointment at, 1654; election of professor, 1802
Fæcal abscess, preliminary evacuation of, and ileo-sigmoidostomy, followed by removal of carcinoma of cæcum, patient well year afterwards (Mr. J. D. Malcolm), 1131
Fæces, examination of, in medical practice (O. Kraus), 95
Fœtal extracts, human action of, upon malignant tumours in man, 1151
Fagan, Sir J., retirement of, 1451
Fagan, Mr. P. J., sudden death of, 1174
Fagge, Mr. C. H., discussion on fractures near joints, 1694; discussion on operative treatment of simple fractures, 350
Fahrenheit and centigrade, 1662
Fairbank, Mr. H. A. T., bilateral congenital dislocation of the patella after operation, 1552
Fairbank, J., the administration of anæsthetics and the V-shaped upper jaw, 59
Fairles-Humphreys, Mr. N. W., elected Mayor of Montgomery, 1641
Fairlie, Mr. H. P., note on two cases of cerebral hæmorrhage associated with anæsthesia, 1415
Faith healing, scientific (leading article), 320
Falgovski, Dr., acute relaxation of the uterus during narcosis by inhalation, 1160
Falke, Dr. E., and Stickler, Prof. A., treatment of inoperable cancer by ferments combined with radium, 1155
"Falling of the womb," 1040; operative treatment of more severe cases (Prof. J. B. Hellier), 933, 961
Falls from great heights, 1148
Falmouth board of guardians and tuberculosis, 1861
Families of medical practitioners, question of remuneration for attendance on, in Austria, 204
Faradic current, use of, in treatment of persistent aphonia following laryngitis, two cases (Dr. F. Hernaman-Johnson), 1340
Faradism of large intestine in treatment of, case of, chronic constipation (Mr. W. J. Burroughs), 799
Fardon, Mr. H. J., grain itch, 337; question of counterblast to quack remedies, 1242
Farm colony, action against for loss of a leg, 1854
Farquharson, Dr. J. M., case with symptoms of cerebro-spinal rhinorrhœa, 1701; angio-neurotic paralysis of right acoustic nerve, 1701
Farquharson, Dr. R., discussion on reform of death certificates, 834; position of homœopathy, 185
Farquharson, Right Hon. R., on the notification of consumption, 224
Fats, The (Prof. J. B. Leathes) (review), 1560
Fauchie-Villeplée M., cancer of the lower lip treated by electro-coagulation, 1654
Faucial pillars, suture of, for hæmorrhage, following tonsillectomy, 745, 1083
Faulder, Mr. T. J., case for diagnosis, 1488; the administration of the Public Health and Education Acts in relation to the prevention and cure of diseases of the throat and nose, 21, 97
Favell, Mr. R., Cæsarean section for concealed accidental hæmorrhage, 1281; hysterectomy for complete rupture of uterus, 1556
Faversham, medical mayor elected at, 1641
Favus, recent experiences in treatment of, 810
Fees, medical, in accident cases, 506; for school accidents and London County Council, 1448; question of, 1183, 1391; under the Midwives Act, 1525; of vaccination officers (Parliamentary question), 141
Feeble-minded, care of, 260; children, West Derby guardians' new scheme for care of, 1246; females, detention of, 73
Feeding of nurses, 1456; of school-children in Chicago, 1586
Feet and hands, gonorrhœal keratosic cones of, 1769
Fehling, Prof. H., Die Operative Geburtshilfe der Praxis und Klinik (The Operative Midwifery of Practice and of the Clinique), 1909 (review), 1282
Feibes, Dr. E., discussion on treatment of tabes dorsalis, 489; recent methods in the diagnosis and treatment of syphilis, 391
Feilmann, Mr. E., discussion on bacteriological standardisation of disinfectants, 422
Fein, Dr. J., Hints for the General Practitioner in Rhinology and Laryngology, 1910 (review), 1141
Feldman, Mr. W. M., Manual of Nursery Hygiene, 1910 (review), 1284
Female students in Paris, coöperative restaurant for, 1520
Females and young persons, industrial employment of, 918
Femur, sarcoma of, case shown, 1696
Fenton, Dr. W. J., and Galloway, Dr. J., case of Stokes-Adams' symptoms, 1762
Ferments combined with radium in treatment of inoperable cancer, 1155
Ferrier, Dr. D., discussion on treatment of tabes dorsalis, 489; pathology of acromegaly, 1765
Ferro-silicon, 245; with special reference to poisonous gases evolved therefrom (Mr. H. W. Hake), 220
Fertility of the unfit, 1516
Fever, long-continued, of obscure causation, cases, 1347; Mediterranean, in village near Lucca, 326, 330; recurrent, in rats, influence of new Ehrlich preparation, dioxydiamido-arsenobenzol ("606") on (Dr. J. McKintosh), 713; (leading article), 740; in West of Ireland, 980
Fever hospital enlargement and Dundee town council, 1381
Fevers from the standpoint of the clinician, 1703
Fevers in Tropics, their Clinical and Microscopical Differentiation (Major L. Rogers) (review), 950
Fibroid of uterus, treatment by X rays (Dr Agnes F. Savill), 1132
Fibroids, uterine, treatment by electricity, 1241
Fibroma, sarcoma, and, fibromyoma of abdominal wall (Mr. C. B. Lockwood), 445
Fibromata, naso-pharyngeal, method of removal, with two illustrative cases (Mr. T. Guthrie), 1271
Fibromyomata complicating pregnancy, treatment of, 559; uterine, intra-peritoneal hæmorrhage in cases of, 814
Fibromyositis, nodular, 1702
Fibrosis of uterus, surgical treatment, 813
Fichera, Dr., action of human fœtal extracts upon malignant tumours in man, 1151
Fife, county of, medical officer for, 261; and Kinross District Board of Lunacy, annual report for year ending July 31st, 1909, 508
"Fifty years of science," 1257
Fildes, Mr. P., and McIntosh, Dr. J., theory and practice of the treatment of syphilis with Ehrlich's new specific "606," 1684
Filigree operation (McGavin's) in treatment of ventral and inguinal hernia, 1835
Filliatre, Dr. Le, adhesions of the epiploon and the bowels to the abdominal wall as a consequence of laparotomies for intervention on the uterus and its adnexa, 1158; advantages of spinal anæsthesia, 1159
Finger-nails, fungus affections of, 1421
Fink, Maj. G. H., dysentery, 835; plea for efficient drainage after cataract extraction, 821
Fink, Dr. L. G., blackwater fever, 847
Finnie, Mr. A. S., abuse of the hospital and its cure, 1105
Finny, Dr. J. M., resignation of, 135
Finzi, Dr. N. S., radium treatment of cancer, 1423
Fire, alarming, at Leeds General Infirmary, 1173; at Belfast hotel, 767; disasters at Toulouse Faculty of Medicine, 1382; outbreak in City Hospital, Aberdeen, 1801; at branch premises of Pasteur Institute, 1802; risks of, precautions against at drapery establishments, 924; tests with flannelette and other textiles, 275
Firssel, Dr., gastric terminology from the radiological standpoint, 1366
First-aid, amateur, 64
First-aid in colliery districts of South Wales, 200
First Aid to the Sick, or Diseases, their Description and Treatment (Mr. S. H. Young) (review), 316
Firth, Mr. A. C. D., and Ledingham, Dr. J. C. G., atypical chloroma, 1551
Fischer, Dr. M., Œdema: a Study of the Physiology and Pathology of Water Absorption by the Living Organism (the 1909 Nathan Lewis Hatfield prize essay of the College of Physicians of Philadelphia, 1910 (review), 1560
Fish, conveyance of bacillus of cholera by, 1227, 1306
Fisher, Inspect.-Gen. J. W., award of Greenwich Hospital pension to, 760
Fisher, Dr. T., cardiac strain, 762
Fisherman's Diary, Fly-leaves from (Capt. G. E. Sharp) (review), 1708
Fissura facialis, specimen, 474
Fistula in Ano, Treatise on, by John Arderne, from Early Fifteenth-Century Translation (review), 172; ureteral, permanent, and colotomy opening, method of establishing by means of elevated and more readily controlled mucous openings, 554; vesico-vaginal, summary of 21 cases operated on (Mr. W. C. Bendall), 796
Fistula, umbilical, case of intestinal obstruction caused by enteroliteh spontaneously cured by evacuation through (Dr. D. M. Greig), 1613
FitzPatrick Lectures on Greek Medicine in Rome (Sir T. C. Allbutt), 1325; Lecture II., 1395

Fitzwilliams, Mr. D. C. L., hereditary cranio-cleido-dysostosis, with a review of all the published cases of this disease: theories of the development of the clavicle suggested by this condition, 1466; (leading article), 1710
Fixation method, complement, diagnostic view of, 475
Flannelette and other textiles, fire tests with, 275
Flatulence, senile, remedy for, 1306
Fleas, destruction of, 1459, 1527; of rats, use of hydrocyanic gas for killing, 1713
Fleig, Dr. C., mineral waters as artificial sera, 1126; subcutaneous injections of natural mineral waters, 183
Fleming, Dr. A., discussion on vaccine therapy, 889
Flemming, Mr. A. L., discussion on open system of ether administration, 555; prolonged anæsthesia maintained by ether and gas alternately, 1487
Fletcher, Mr. H. N., boy with swelling on lower part of tibia, 1702
Flexner, Dr. S., recent studies in epidemic poliomyelitis (leading article), 1711
Flies, destruction of, 76; and house refuse deposits, 323; as carriers of infection, 1025 (see also House-fly)
Flock, unwashed, for bedding, prohibition of use of, deputation to Mr. Burns, 120; bedding, dirty (Parliamentary question), 440
Flood water, diversion of, at Belfast, 1107
Flora of Algeria (Dr. A. S. Gubb) (review), 1838
Florence, brigandage near, 246
Flour, adulteration of, 273; bleached, 116, 843; (Parliamentary question), 207
Fœtus, Malformations and Congenital Affections of (Klinik der Missbeldungen und Kongenitalen Erkrankungen des Fötus) (Prof. R. Birnbaum) (review), 382
Folker, Dr. H. H., discussion on administrative control of ophthalmia neonatorum, 569
Fontoynont, M., gynæcology in Madagascar, 1731
Food Congress, 1689
Food for school children, 1801; in shops, hygienic measures for, in Rome, 1257; poisoning bacilli, 391; preservatives, 901; requirements of man for sustenance and work, 403
Food and Hygiene (Dr. W. Tibbles) (review), 806
Food-supply in Paris during railway strike, 1243
Food Testing, Elementary Course of (Mr. B. A. Burrell) (review), 1839
Foods, diabetic, 467; milk, 467; and Drugs, Microscopical Examination of (Prof. H. G. Greenish) (review), 1426
Foodstuffs, various, use of, in preventing dental caries, 397
Footpaths, public, dogs on, resolution at Brighton and Sussex Medico-Chirurgical Society, 1769
Forceps, laryngeal, improved, 1286; nasal punch, 1144
Foreign body in abdomen, intestinal obstruction due to, presumably introduced through perforation in uterus, 1092
Foreign bodies in bronchus, 1682
Foreign medical men, deaths of, 70, 147, 264, 421, 590, 784, 857, 921, 985, 1177, 1252, 1387, 1427, 1588, 1657, 1866
Foreign medical practitioners in Italy, 114
Foreign university intelligence, 439, 595, 1178
"Forensicus," notification of consumption, 432
Forest fires, 416
Forfarshire joint committee and use of paraffin for pediculosis, 1047
Forfarshire Medical Association, annual meeting, 201
Formaldehyde with chinosol, intravenous injections of, in treatment of pulmonary tuberculosis (Mr. J. McElroy), 1408
Forrester, Mr. G. P., organic preparations of arsenic, 1858
Forssell, Dr., experience in the radium-therapy of cancerous tumours, 1367
Forster Green Hospital, Belfast, 1863
Fortescue-Brickdale, Dr. J. H., comparative therapeutic values of the organic and inorganic compounds of certain elementary bodies, 828
Forthill burying ground (Parliamentary question), 141
Foster, Sir Walter (see Ilkeston, Lord)
Fothergill, Dr. E. R., discussion on Poor-law reform and the medical profession, 408
Foulkes, Mr. P. G., grain itch, 431
Fowler, Mr. G. S., and others, oxidation of phenol by certain bacteria in pure culture, 1783
Fowler, Sir J. K., discussion on vaccine therapy, 887; knighthood conferred upon, 1290
Fox, Dr. R. Hingston, the fertility of the unfit, 1516
Foxwell, Dr. A. (the late), 1736
Foy, Dr. G., status lymphaticus in its relations to the use of anæsthetics in surgery, 587
Fracture of leg, ambulatory treatment of, 1654; of both patellæ, two cases occurring at intervals of 10 and 13 years respectively, 1557; compound, with tetanic symptoms, two cases, recovery after injection of anti-tetanic serum (Mr. E. K. Williamson), 1485; healed, of right temporal bone, 1551
Fractures, new apparatus for treatment of, 767; new method of extension in, 1863; operative treatment of, 501; simple, operative treatment of, 348; and Dislocations, Practical Treatise on (Dr. L. A. Stimson) (review), 550; Joint, and Dislocations (Dr. F. J. Cotton) (review), 1015; in neighbourhood of joints (Mr. R. Jones), 1479, 1486, 1648; and Separated Epiphyses (Mr. A. J. Walton) (review), 1017; of elbow, treatment in children, 1802; of base of skull, treatment by repeated lumbar puncture, 1026; of skull, vomiting of brain tissue in, 963
Fraenkel, Dr., vaginal incision, 1157
France, cholera in, 1508; depopulation of, 1584; early operations for cataract in, 1715; foreign medical practice in, 691; precautions against cholera in, 1314; sanatoriums in, defective personal hygiene prevailing at (wet day at an air and water cure), 913
Francis, Dr. H. A., probable explanation of the effect of nasal cauterisation in asthma and other vaso-motor neuroses, 478
Francis of Teck, H.S.H., death of, 1290; efforts and work of, in connexion with Middlesex Hospital, 1358

Mills, Dr. G. P., effect of radium on a healthy tissue cell, 462
Milne, Mr. J. W., heart puncture, 377, 588
Milne, Dr. R., defence of the home treatment and prevention of scarlet fever, 834
Milner, Mr. S. W., notes on a case of infection of the base of the brain from a carious tooth, 1416
Mind, evolution of, 1188; heredity in relation to (Harveian Oration) (Dr. H. B. Donkin), 1187
Minehead, water-supply of, 765
Mineral water injections into tissues, clinical application of, 1128
Mineral waters as artificial sera (Dr. C. Fleig), 1126; Boulou natural, 1143; Glashagen, 894; natural subcutaneous injections of, 183
Mines, accidents in, 73; rescue work in, 1869
Minority Report, medical proposals of, 335
Missionaries, medical training of, 63
Missionary Conference at Edinburgh, 63
Mitchell, Dr. A. P., M'Cunn scholarship awarded to, 1389
Mitchell, Dr. W., diagnosis by means of X rays, 1348
Mitral stenosis, meaning of audible signs in, 1167, 1239; (Dr. A. Morison), 1073
Models, wax anatomical, sale of, 1658
Moffatt, Mr. E. W. P., Science German Course, 1910 (review), 1708
Molar teeth, growth of, in relation to development of antrum of Highmore, 389
Molluscum contagiosum, some varieties of, 811
Molony, Dr. J. B., note on an unusual case of lipoma, 1549
Molony, Dr. J. B., and Rolleston, Dr. H. D., idiopathic hypertrophic dilatation of the colon, 1345
Mongolia, plague in, 975
Monmouthshire, water supply of western valleys of, 517
Monmouthshire Asylum at Abergavenny, report for year 1909, 973
Monsarrat, Mr. K. W., case of osteitis deformans, exhibited, 1703; discussion on pyloric stenosis in infancy, 1347
Monstrosity, case of, 60
Montgomery, medical mayor re-elected at, 1641
Montreal, mortality from consumption decreasing in, 1733; sanitary conditions in, 433
Moore, Prof. B., discussion on falling birth-rate, 816; economic basis of hospital management, 350
Moore, Dr. F. C., and Kilroe, Dr. L., use of belladonna in dyspepsia, 1550
Moore, Sir J. W., address on some recent clinical experiences, 1616; appointment of, as deputy lieutenant for the county of city of Dublin, 767; Meteorology, Practical and Applied, 1910 (review), 1837
Moore, Dr. Norman, the Bolingbroke lecture, entitled "An Exercise on Heart Disease," 213
Mooren's ulcer of cornea treated by zinc ionisation, 406
Morals, Public, National Council of, 1859
Morel-Lavellée, treatment of the morphine habit, 767
Morgan, Mr. G., unusual case of gland infection, 890
Morgan, Mr. J. H., C.V.O., promotion to, in Order of Hospital of St. John of Jerusalem, 503
Morgan, Dr. W. P., discussion on vaccine therapy, 888
Morison, Dr. A., discussion on heart strain and dilatation, 1697; heart puncture, 516; lymphatic leukæmia in a woman, associated with rheumatoid arthritis, 1557; meaning of audible signs in mitral stenosis, 1073, 1239
Morison, Prof. R., and Drummond, Dr. H., dermoid tumours, 1336
Morison lectures on epilepsy, abstract of, delivered before the Royal College of Physicians of Edinburgh (Dr. W. A. Turner), 147, 217
Morphia habit, treatment of, 767, 1104; by "pantopon," 1169; and quinine, influence of, upon phagocytosiss (Dr. H. L. Smith), 1342
Morphine and chloroform, murder by, followed by suicide by illuminating gas, 885
Morphine, use of, in pneumona (Capt. W. E. McKechnie), 942, 963
Morrell, Mr. R. A., preliminary observations on some cases of esophoria not caused by refractive errors, 1274
Morris, Mr. S. G., honour conferred upon, 1716
Morrison, Prof. J. T., discussion on spinal analgesia, 808
Mortality, English urban, in the past summer, 1228; excess of, in colliery districts, 746: urban, in the United Kingdom, recent, 248; and operations, 1240
Morton, Deputy Inspec.-Gen. Charles (obituary), 911
Morton, Dr. C. J., discussion on operative treatment of simple fractures, 350
Morton, Dr. E. R., preliminary note on the treatment of rodent ulcer by solid carbon dioxide, 130, 198, 258; skiagrams of case of syphilitic disease of elbow-joint, 1492; some bony changes observed in case of chronic X ray dermatitis, 406; use of solid carbon dioxide in dermatology, 558; and Harman, Mr. N. B., use of carbon dioxide snow in eye work, 484
Morton, Dr. H., medical research award, 340
Morton, Dr. R., and Orton, Dr. G. H., Royal Society of Medicine, Electro-Therapeutical Section, 1649
Mortuary, wanting at Crewe, 1312
Mosquito curtain, difficulty of ventilation with (leading article), 741; special, steamer provided with, 130
Mosquito screens, special, in ss. *Vincent*, 517
Mosquitoes in Austria-Hungary, 594; Bentley-Taylor method of mounting, 1551; and malaria, 988
Mosquitoes and Malaria (Maj. R. J. Blackham) (review), 1018
Mossman fever, 1948
Mosso, Senator Angelo, obituary, 1656
Mother aad Child, practical analysis of human breast milk, with regard to clinical conditions of, 812
Motor-car hiring trade, alleged custom of, 1851
Motor-cars of medical men, question of speed on visits to patients, 1048
Motor Exhibition at Olympia, London (Mr. C. T. W. Hirsch), 1362, 1433
Motor functions of the stomach, 1939
Motoring notes (C. T. W. Hirsch), 48, 250, 581, 966, 1032, 1573, 1851
Mott, F. W., comparative neuro-pathology of human trypanosomiasis and syphilis, 1214; effect of alcohol on the nervous system, 599; Huxley lecture on hereditary aspects of nervous and mental diseases, delivered at the opening of the winter session at Charing Cross Hospital, 1057; (leading article), 1090; Oliver-Sharpey lecture on the cerebro-spinal fluid, delivered before the Royal College of Physicians of London, Lecture II, 79; Syphilis of Nervous System (vol. iv. System of Syphilis), 1910 (review), 1084
Moullin, Mr. C. M., essential cause of gastric and duodenal ulcer, 993
Mountbellew dispensary district in county Galway, well-fought election of medical officer, 1730

Moure, M. E. J., and Bouyer, M. A., Abuse of the Singing and Speaking Voice, Causes, Effects, and Treatment, 1910 (review), 1284
Mouse cancer, air-dried, experiments with, 1550
Mousseos, Dr. B., Les Formes Larvées du Paludisme: Diagnostic et Traitement, 1910 (review), 1494
Mouth, care of, during general disorders, 398
Moynier, M. G., death of, 890

Poor-law medical reform and Majority and Minority reports of Royal Commission, 977; what it should aim at (Dr. M. Greenwood), 46
Poor-law reform, 976, 1519; Commission's two reports, 1041; proposed, some medical aspects of (Dr. M. Greenwood), 56; and medical profession, 121; from general practitioner's point of view, 760; in Ireland, 916; in relation to public health and the medical profession, 407
Poor-law treatment of consumptives, 1171
Pope, Dr. C., Practical Hydrotherapy, 1909 (review), 806
Popper, Dr. H., and Obermayer, Prof. H., the demonstration of bile-pigment in blood serum and in serous exudates, 1569
Poppy heads, poisoning by decoction of, in France, 1249
Population, estimates of, and the Census (leading article), 110
Pór, Dr., treatment of acne rosacea by tonogen, 1384
Pornography, repression of, in Italy, 203, 1049
Portadown, insanitary condition of, 1047
Porter, Dr. C., Sanitary Law in Question and Answer, 1910 (review), 1838
Porter, Dr. W. G., clonic spasm of right vocal cord and soft palate, 1701; patient shown two years after operation on right labyrinth, 1700
Portfolio of Dermochromes, by Professor Jacobi of Freiburg, 1910 (review), 1882
Porto Rico, public health of, 518
Portsea improvement scheme, 503
Portugal, foreign medical practice in, 695
Port-wine stain, congenital, of right face and neck, 1833
Post-graduate courses at Royal Victoria Infirmary at Newcastle, 338
Post-graduate study, information as to, 699
Post-Graduates' Medical College and Polyclinic, introductory address (Dr. R. Jones), 1196
Post-nasal space, tumour of, 1488
Post Office authorities, action of, in case of measles, 197; measles and, 59
Postural causes, cranial asymmetry of infants due to, 1492
Potassium bichromate, use of, in treatment of phthisis (Dr. J. B. Tombleson), 1484
Powell, Dr. H. W. F., and Badgerow, Dr. G. W., tumour of the post-nasal space, 1488
Powell, Sir R. D., discussion on heart strain and dilatation, 1615
Powell, Prof. S. A., Bentley-Taylor method of mounting mosquitoes, 1551
Power, Mr. D'Arcy, address on the diagnosis and treatment of cystic disease of the breast, delivered before the Harveian Society of London, 1416, 1604
Practice, General, Operations of (Mr. E. M. Corner and Mr. H. T. Pinches) (review), 173
Practice, unqualified, in Germany, 1732
Practice, unqualified, report on, 1659
Practitioners, general, duty of, to deaf children (Mr. M. Yearsley), 781; right methods of keeping them abreast of modern developments, 102
"Prana" carbon dioxide snow apparatus, 1840
Pratique, La, des Maladies des Enfants (Diagnostic et Thérapeutique), vol. iii. (Diseases of the Appendix, Peritoneum, Liver, Kidneys, Pancreas, Blood, and Lymphatic Glands), 1910 (review), 804
Prausnitz, Dr. C., and Turner, Mr. N. H., Dr. C. E. Harris fund, 763
Precipitin reaction, interpretation of, 556
Pregnancy, complicated by fibro-myomata, treatment of, 559; concurrent extra- and intra-uterine, case of, 1276; extra-uterine, occurring twice in same person, 101; case of (Dr. W. W. Stainthorpe), 462; removal of fœtal skeleton, recovery, 1584; full-term ectopic, 1281; hygiene of, 65; Myoma in (Dr. T. Landau) (review), 173; ovariotomy through vaginal method during, 1157; toxæmia of, value of blood pressure determinations in (Dr. H. J. Starling), 784; twin, diagnosis of, new sign of, 1293; vaginal route in cases of, complicated by cancer of uterus, 1157
Pre-pulmonary tuberculosis, diagnosis in school inspection (Dr. W. Ewart), 308
Prescriber's Companion (Dr. T. D. Savill) (review), 1707
Prescriptions, medical, law relating to, 1019; ownership of, 1724, 1795 (Mr. H. W. Gadd), 1030; property in, 1168, 1241; of practitioners; rights of property of (leading article), 1428
Presentations and testimonials: to Dr. W. Alexander, 199; to Sir James and Lady Barr, 1379; to Mr. C. J. Bond, 1737; to Sir Thomas Crosby, 1319; to Mr. W. F. Dearden, 1456; to Lieut.-Col. H. P. Dimmock, 1804; to Dr. J. Graham, 135; to Dr. J. R. Kaye, 1096; to Mr. J. H. Marsh, 1096; to Sir G. O'Farrell, 1174; to Prof. A. Ogston, 979; to Mr. H. A. Pattinson, 766
Preservatives, food, 901
Presidential address at the meeting of the British Medical Association in London (Dr. H. T. Butlin), 279; annotation, 321
Presidential address on strain (Sir L. Brunton), delivered at the annual meeting of the Ipswich Medical Society, 531
Pressor substances in urine in case of acromegaly with hypertrophied heart, 552
Pre-tuberculosis, diagnosis of, in relation to school inspection (Dr. W. Ewart), 308

Preventive and administrative measures for the control of tuberculosis in New York City (Dr. H. M. Biggs), 371
Price, Dr. G. B., discussion on special factors influencing suitability of Europeans for life in tropics, 493
Price-Jones, Dr. C., alterations in size of red blood corpuscles, 827
Pricota (apricot liqueur), 34
Pridham, Mr. G. H., note on a case of apical pneumonia with meningeal symptoms, 1549
Prince, Dr. M., Psychotherapeutics (review), 316
Prince Francis of Teck memorial fund, 1513
Prince of Wales General Hospital, Tottenham, N., information for students, 638
Pringle, Mr. S., transperitoneal cystotomy for tumour of the bladder, with report of a case, 1698
Prison Congress, Fifth International, 1586
Prison reform, 1568; common sense in (leading article), 1843
Prisons, report of Commissioners of, for year ended March 31st, 1910, 1440
Prisons in Egypt, sanitation of, 1513
Pritchard, Dr. E., banana flour in infant feeding, 812; case of achondroplasia, 1344; grain itch, 587
Pritchard, Dr. H., transposition of viscera with congenital heart disease, 1493
Pritchard, Dr. U., discussion on syphilis in relation to otology, 1489
Prizes and performances (Dr. S. S. Sprigge), 1068
Proctoclysis, continuous, 35, 1517, 1580
Professors, extraordinary, of German Universities, position of, 518
Progressive Medicine: a Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences (review), 948
Prolapse of rectum, operation for, 1242
Property in prescriptions, 1168, 1241
Proptosis, double, due to growth invading each orbit, 1763
Prostate, hypertrophy of, profuse hæmaturia, first symptom of, 1228; obstruction of, relief of symptoms by electrical treatment (Dr. J. S. Bolton), 1009
Prostatic enlargement, pathology of (Mr. F. T. Paul), 294
Prostatitis and spermato-cystitis, typhoid, 502
Proteid, Determination of Different Forms in Blood and Meat (Praktische Anleitung zur Ausführung des Biologischen Eiweiss-differenzierungsverfahrens, &c.), (Dr. P. Uhlenhuth und O. Weidanz) (review), 103
Proteid food, Huxley's, 1142
Protein ("Bence Jones"), nature of, found in urine in case of multiple myeloma (Dr. O. T. Williams and others), 1403
Protozoal disease, ulcerating granuloma of pudenda as, 1628; (Capt. R. M. Carter), 1128
Protozoology (Prof. G. N. Calkins) (review), 313
Prout, Dr. W. T., discussion on human trypanosomiasis, 409
Provision of Meals Act, administration of, 1625; by London County Council, 1506
Provisional Federal Council for the Australian Order of District Nursing, first meeting, 1110

Territorial training, 195
Testicle, dermoid cyst of, associated with new growth (Mr. F. J. F. Barrington), 460
Testis, chondro-carcinoma of, case (Mr. W. Sheen and others), 874; malignant disease of, radical operation for (Mr. Russell Howard), 1406; undescended, association of appendicitis with, 1767
Tetanic symptoms accompanying two cases of compound fracture, recovery after injection of anti-tetanic serum (Mr. E. K. Williams), 1485
Tetanus, treatment of, by atropine, 60
Tetany, recurrent, 1345
Text-books, medical, 1818
The Views of "Vanoc": an Englishman's Outlook, 1910 (review), 1882
Thain, Mr. L. L., point in pharmacology, 1306
Therapeutics, ocular, future of, 483; in ancient Rome, 1399; plea for study of, 1344; Pocket, and Dose-book (Dr. Morse Stewart) (review), 238
Thermo-electric bath, effects of, 341
Thom, Mr. G., stovaine, its use in the treatment of shock, &c., in injuries of the lower extremities, 1014
Thomas, Dr. B. A., treatment of ulcers of the leg by a paste of gelatin, glycerine, and zinc oxide, 1716
Thomas, Dr. G. D., obituary, 520
Thomas, Dr. H. W., steamer with special mosquito screens, 130
Thomas, Dr. W. D., obituary, 1177
Thompson, Dr. A. F., fatal accident to, 62
Thompson, Dr. A. H., operative treatment of high myopia, 566
Thompson, Mr. G. S., breaking-down gummata of liver simulating tropical abscess, 1415
Thompson, Prof. Sir J. J., address on X rays, 406
Thompson, Prof. R. L., and Ochsner, Prof. A. J., Surgery and Pathology of the Thyroid and Parathyroid Glands, 1910 (review), 1350
Thomson, Prof. A., discussion on epithelioma of tongue, 1420; "le rheumatisme tuberculeux" of Poncet of Lyons, 1347; pathological anatomy of cancer of the stomach and the conditions which are mistaken for it, 554
Thomson, Dr. D. G., post-graduate curriculum and diploma in psychological medicine, 830
Thomson, Dr. F. G., acute toxic polyneuritis, 1348
Thomson, Prof. H. A., patient after removal of impacted stone from the lower end of each ureter, 1834; periosteal sarcoma of right humerus, case shown after operation, 1834
Thomson, Dr. StClair, discussion on direct examination of œsophagus and lower air passages, 397
Thorax, dorsal percussion of, 101; hernia of stomach into, 1135
Thorburn, Prof. W., introductory address at Medical Department, University of Manchester, on "the evolution of surgery," 1072
Thorne, Mrs. Isabel (obituary), 1151
Thorpe, Mr. E., and Harris, Dr. C. J. J., note on CO poisoning at the Whitehaven pit disaster, 1693
Threadworms, treatment of, 778, 860
Thresh, Dr. J. C., and Mr. J. F. Beale, practical sterilisation of potable waters by means of ultra-violet rays of light, 1849
Throat, cancer of, 815
Throat hospitals and school children, 97
Throat and nose, administration of Public Health and Education Acts in relation to diseases of (Mr. T. J. Faulder), 2197
Throat pastilles, medicated, 1495
Thrombosis of inferior mesenteric vein (Mr. A. A. Straton), 311; of the lateral sinus, three cases of (Mr. J. Walker Wood), 1210; primary, in pulmonary artery, fatal cases of, 824
Thrombotic softening of spinal cord, cause of so-called "acute myelitis," 1723 (Dr. H. C. Bastian), 1531
Thymus, enlarged, and sudden death, 1493
Thymus, treatment of carcinoma, 931
Thyroid extract, case of chorea treated by, 1276; gland, seaweed in disease of, 842
Thyroid, and Parathyroid Glands, Surgery and Pathology of (Prof. A. J. Ochsner and Prof. R. L. Thompson) (review), 1350
Tibbles, Dr. W., discussion on infantile diarrhœa, 1556; Food and Hygiene, 1910 (review), 806
Tibet, ancient anatomical drawings from, 1149
Tibia, swelling on lower part of, 1702
Tilley, Mr. H., remarks on laryngology, tribute to Sir Felix Semon, 396; vulsellum catch-forceps for the more efficient removal of imbedded tonsils, 1563
Time-gun and Dundee Royal Infirmary staff, 1653
Tissue-cell, healthy, effect of radium upon (Dr. G. P. Mills), 462
Tissue infection, local, leucocytosis of, 89
Tissues, mineral water injections into, clinical application of, 1128; and organs, strain of, 531
Tivy, Mr. William J., obituary, 264
Tobacco, pure, 1527; scent in, 1431, 1870; influence of, on digestion, 1935
Tocher, Mr. J. F., discussion on bacteriological standardisation of disinfectants, 423
Tod, Mr. Hunter, discussion on aural tuberculosis in children, 486; discussion on infective labyrinthitis, 567; value of ossiculectomy in chronic middle-ear suppuration as a means of avoiding the complete mastoid operation, 715
Toes, webbed, bi-parental inheritance of, pedigree showing (Dr. H. P. Newsholme), 1690
Tolstoy, Count, physician of, 1865
Tombleson, Dr. J. B., on the use of potassium bichromate in the treatment of phthisis, 1484
Tomkinson, Dr. J. G., discussion on treatment of syphilis, 393; pityriasis rubra pilaris, 810
Tonga Islands (see Friendly Islands)
Tongue, epithelioma of, 1419
Toni-kola, 1495
Tonkin, Dr. J. H., case of Henoch's purpura with intussusception, 802
Tonogen in treatment of acne rosacea, 1384
Tonsil, anatomy of capsule of, its significance in treatment of diseases of tonsil, 814; the pharyngeal, 389
Tonsillectomy followed by hæmorrhage, suture of faucial pillars for, 745, 1083
Tonsils, enucleation of, with guillotine (Dr. S. S. Whillis and Mr. F. C. Pybus), 875; removal of, statistics of, 23; and adenoid growths, removal of, followed by death, 1294; and adenoids, hypertrophic, 732; imbedded, vulsellum catch forceps for more efficient removal of, 1562
Tooth, carious, infection from, to base of brain, case of, 1416
Toothbrush drill, 76, 1054
Torquay Medical Charities, 1014; medical service at, 1449; Nurses' Institution, 1506; proposal to establish medical baths at, 1591
Toronto Free Hospital for Consumptives, 1798
Toronto, Health Department of, 1733
Toulouse Faculty of Medicine, disastrous fire at, 1382
Tousey, Dr. S., Medical Electricity and Roentgen Rays (review), 1219

Toxæmia of pregnancy, value of blood-pressure determinations in (Dr. H. J. Starling), 784
Toxicological tests for colchicine, 1432
Toxicology, Medical Jurisprudence and Public Health, Manual of (Dr. W. G. A. Robertson) (review), 1285; and Jurisprudence, Medical (Dr. J. Glaister) (review), 802
Toxins, action of radium on, 1366
Tractor, new, for use with midwifery forceps, 550
Traffic of the streets, and children, 247
Trains, sterilised, on Italian lines, 1053
Transfusion of blood, direct, in treatment of hæmorrhage in new-born, 1433
Traquair, Dr. H. M., treatment of purulent keratitis by zinc iontophoresis, 484
Treatment, Medical, Text-book of (Dr. W. Calwell) (review), 30; of embolism of the femoral artery by immediate massage, 962
Trephine, safety, 553
Trephining in simple fractures of skull, 1520
Treponema pallidum in congenital gummata, distribution of (Dr. E. A. Shaw), 26
Treupel's, Prof., clinic, visit to, use of "606" (Dr. J. G. Garson), 964
Trevelyan, Dr. E. F., child with partial paralysis of right shoulder muscles, exhibited, 1557
Treves, Sir F., Bart., voluntary aid detachments, 1516
Treves, Sir F., Bart., and Hutchinson, Mr. J., Manual of Operative Surgery, 1910 (review), 1836
Trial of H. H. Crippen, 1299
Trigonum vesicæ, 390
Trinidad, medical administration in, 904
Trinity College, Dublin information for students, 657
Tripoli, cholera in, 1509, 1791
Troops, Indian, station hospitals for, 519
Tropical abscess, breaking-down, gummata of liver assimilating, 1415
Tropical Diseases, Hospital and School for, in Hamburg, 580
Tropical Medicine, Section of, in Medical Museum of British Medical Association, 750; marine, floating laboratory for study of (Mr. A. Balfour), 55; and Parasitology, Annals of, vol. iv., No. 1, Amazon Yellow Fever Expedition (review), 315
Tropical medicine and hygiene, examination in, University of Cambridge, 679
Tropical medicine, diplomas in, support from University of Liverpool, 1652; memorial as to, discussed at General Medical Council, 1590
Tropics, cost of sanitation in, 1103; diseases of (Parliamentary question), 140; Fevers in, their Clinical and Microscopical Differentiation (Dr. L. Rogers) (review), 956; life in, special factors influencing, suitability of Europeans for, 492

Trousseau, Dr. A., fatal accident to, 1452
Trypanosoma gambiense, transmission of, 323
Trypanosomiasis, and the cinematograph, 1861; human, 408; new human, from Rhodesia, 1572; treatment of, by organic compounds of antimony and arsenic, 1175; and syphilis, comparative, neuropathology of, 1314
Tubercle in milk-supply of Glasgow, 340
Tubercle bacillus, acid-fast, relation of, to other forms of bacterial life, 1359
Tuberculin, action of ultra-violet rays on, 1863; injection of, into skin, serious result of, 248; test, distrust of, 252; treatment of out-patients, 341; in treatment of pulmonary phthisis, 553; use of, in prevention, diagnosis, and treatment of tuberculosis, 1421; in treatment of laryngeal tuberculosis, 473; "Wellcome" brand, 34
Tuberculosis, avenues of infection in, 186; combat against (Parliamentary question), 360; diagnosis of pre-tuberculosis in school inspection (Dr. W. Ewart), 308; dispensary at Cardiff, 1246; dread of, 134; First Spanish International Congress of, 1357; frequency of, in childhood, 119; heliotherapy in, 1633; incidence of, in children, with special reference to school attendance (Dr. J. E. Squire), 373; industrial (Dr. T. D. Lister), 1122; International Congress of, date and place of meeting, 844; mortality from, in Ireland, 1909, 1233; Muskoka sanatoriums for, 1041; Ninth International Conference on, permanent commissions, influence of predisposition and heredity, royal messages, 1244, 1245; and milk-supply, a question of procedure raised at Sunderland, 1853; notification of, 432; a Preventable and Curable Disease (Dr. S. A. Knopf) (review), 383; prevention of, 118, 1045; Conference on, 117, 186; Conference at Edinburgh, 251; its diagnosis and treatment by use of tuberculin, 1421; in Ireland, 188; preventive measures and administrative control of, 187; (Dr. E. W. Hope), 164; (Dr. H. Scurfield), 166; problem, duty of public in regard to (leading article), 37; of State intervention, 252, 255; question whether present in pig's carcass offered for sale, 1174; relation of, to generative functions (Dr. J. T. R. James), 233; Section of, in Medical Museum of British Medical Association, 749; some features of, in India, 409; Surgical, Ionisation in (Dr. G. B. Massey) (review), 1351; treatment of, on Mediterranean coast, 1249; heliotherapy, 1435; working man in relation to, 120; (see Meningitis, tuberculous)
Tuberculosis, abdominal, susceptibility of children to, 252; acute general leucopenia in, 88; aural, in children, 485; laryngeal, treatment by injection of alcohol, 1701; treatment of dysphagia in, 1847; use of tuberculin in treatment of, 479; pulmonary, prognosis in, 747; treatment by artificial pneumothorax, 202; by drugs, 1505; by intravenous injections of chinosol with formaldehyde (Mr. J. McElroy), 1408; 20 cases treated by continuous antiseptic inhalation (Dr. D. B. Lees), 1475; as problem of administration (Dr. A. K. Chalmers), 167
Tuberculosis in childhood, incidence of, 251
Tuberculosis Exhibition, Liverpool, 133
Tuberculosis in New York City, measures for control of (Dr. H. M. Biggs), 371
Tuberculosis and sisterhoods, 188
Tuberculous abscess of neck, 889; cripples, conservative treatment of, 394; gland, its significance and treatment (Dr. R. W. Philip), 19
Tuberculous disease of knee-joint, old healed, 1696
Tuberculous ulcer of ileum, perforated, 1763
Tubes, metal, treatment of central osteitis with, 1846
Tuckey, Dr. C. L., discussion on hypnotism in relation to surgical anæsthesia, 1765
Tumour, relation of, to organism, 266
Tumours, immediate microscopic diagnosis of, at time of operation (Mr. E. H. Shaw), 939, 959; innocent, of breast, recurrence after removal of, 112; malignant, growth and structure of, 266; produced by surgical dressings, 135
Tunbridge Wells General Hospital, 1209
Tunis, increased facilities for sale of quinine in, 202
Tunisia, cholera in, 1162, 1508, 1585, 1790; foreign medical practice in, 695
Turkey, Asiatic, cholera in, 1790
Turkhud, Dr. V. A., obituary notice, 1524
Turnbull, Dr. H., pathological report of case of pernicious anæmia terminating in acute diabetes, 544
Turnbull, Dr. H. H., discussion on effect of digitalis on human heart, 487; experimental administration of drugs of digitalis group, 1615
Turnbull, Dr. H. M., pathological report on benign cyst of humerus, 1206
Turner, Dr. A. L., case of laryngeal tuberculosis treated by injection of alcohol, 1701; two cases of acute lepto-meningitis complicating middle-ear suppuration, recovery, 1701
Turner, Dr. D., pigmented nævus, with hairs of left ocular region, case exhibited, 1833; port-wine stain of congenital origin, case exhibited, 1833
Turner, Dr. D., and George, Dr. T. G., some experiments on the effects of X rays in therapeutic doses on the growing brains of rabbits, 491
Turner, Mr. H. C., obituary, 985
Turner, Mr. J. G., value of teeth to the human economy, 818
